The Division Algorithm in Sextic Truncated Moment Problems

Raúl E. Curto and Seonguk Yoo

Abstract. For a degree $2n$ finite sequence of real numbers $\beta \equiv \beta^{(2n)} = \{\beta_{00}, \beta_{10}, \beta_{01}, \cdots, \beta_{2n,0}, \beta_{2n-1,1}, \cdots, \beta_{1,2n-1}, \beta_{0,2n}\}$ to have a representing measure $\mu$, it is necessary for the associated moment matrix $\mathcal{M}(n)$ to be positive semidefinite, and for the algebraic variety associated to $\beta$, $\mathcal{V}_\beta \equiv \mathcal{V}(\mathcal{M}(n))$, to satisfy $\text{rank } \mathcal{M}(n) \leq \text{card } \mathcal{V}_\beta$ as well as the following consistency condition: if a polynomial $p(x,y) \equiv \sum_{ij} a_{ij} x^i y^j$ of degree at most $2n$ vanishes on $\mathcal{V}_\beta$, then the Riesz functional $\Lambda(p) \equiv p(\beta) := \sum_{ij} a_{ij} \beta_{ij} = 0$.

Positive semidefiniteness, recursiveness, and the variety condition of a moment matrix are necessary and sufficient conditions to solve the quadratic ($n = 1$) and quartic ($n = 2$) moment problems. Also, positive semidefiniteness, combined with consistency, is a sufficient condition in the case of extremal moment problems, i.e., when the rank of the moment matrix (denoted by $r$) and the cardinality of the associated algebraic variety (denoted by $\nu$) are equal.

For extremal sextic moment problems, verifying consistency amounts to having good representation theorems for sextic polynomials in two variables vanishing on the algebraic variety of the moment sequence. We obtain such representation theorems using the Division Algorithm from algebraic geometry. As a consequence, we are able to complete the analysis of extremal sextic moment problems.

1. Introduction

Given a doubly indexed finite sequence of real numbers \( \beta \equiv \beta^{(2n)} = \{ \beta_{00}, \beta_{10}, \beta_{01}, \ldots, \beta_{2n-1,1}, \ldots, \beta_{1,2n-1}, \beta_{2n,0} \} \), the truncated real moment problem entails finding a positive Borel measure \( \mu \) supported in the real plane \( \mathbb{R}^2 \) such that

\[
\beta_{ij} = \int x^i y^j \, d\mu \quad (i, j \in \mathbb{Z}_+, \ 0 \leq i + j \leq 2n).
\]

The sequence \( \beta \) is called a truncated real moment sequence (of order \( 2n \)) and \( \mu \) is referred to as a representing measure for \( \beta \). We next associate a moment sequence \( \beta \) to the moment matrix \( \mathcal{M}(n)(\beta) \) defined by

\[
\mathcal{M}(n)(\beta) := (\beta_{i+j})_{i,j \in \mathbb{Z}_+^2; |i|, |j| \leq n};
\]

we then introduce the following lexicographical order on the rows and columns of \( \mathcal{M}(n) \): \( 1, X, Y, X^2, XY, Y^2, \ldots, X^n, \ldots, Y^n \). The column space of \( \mathcal{M}(n) \) will be denoted by \( \mathcal{C}_{\mathcal{M}(n)} \).

Let \( \mathcal{P} \equiv \mathbb{R}[x, y] \) be the space of bivariate polynomials and for \( k \geq 1 \), let \( \mathcal{P}_k \) be the subspace of \( \mathcal{P} \) whose polynomials are of degree less than or equal to \( k \). The Riesz functional \( \Lambda \equiv \Lambda_{\beta} : \mathcal{P}_{2n} \to \mathbb{R} \) maps a polynomial \( p(x, y) \equiv \sum_{i,j \geq 0; 0 \leq i+j \leq 2n} a_{ij} x^i y^j \) in \( \mathcal{P}_{2n} \) to \( \Lambda(p) := \sum_{i,j \geq 0; 0 \leq i+j \leq 2n} a_{ij} \beta_{ij} \); it is obvious that the presence of a representing measure \( \mu \) implies the identity \( \Lambda(p) = \int p \, d\mu \). We also let \( p(X, Y) := \sum_{i,j \geq 0; 0 \leq i+j \leq 2n} a_{ij} X^i Y^j \); \( p(X, Y) \) is thus an element in \( \mathcal{C}_{\mathcal{M}(n)} \).

In what follows, \( \hat{p} \) stands for the coefficient vector \( (a_{ij}) \) of \( p \); the fact that \( \mathcal{M}(n) \) is a symmetric matrix can be characterized by the equation

\[
\langle \mathcal{M}(n) \hat{p}, \hat{q} \rangle = \Lambda(pq) \quad (p, q \in \mathcal{P}_n).
\]  

We are now ready to list some necessary conditions for the existence of a representing measure \( \mu \) for \( \beta \). We start with positive semidefiniteness of \( \mathcal{M}(n) \); since \( \langle \mathcal{M}(n) \hat{p}, \hat{p} \rangle = \Lambda(p^2) = \int p^2 \, d\mu \), and \( \mathcal{M}(n) \) is symmetric, it follows that \( \mathcal{M}(n) \) is positive semidefinite (in symbols, \( \mathcal{M}(n) \geq 0 \)).

The next necessary condition is related to the support of the measure. To date, there is no general algorithm to find the support of a representing measure for the nonsingular truncated moment problems, while there are concrete results in the singular case. Naturally, the atoms of a representing measure lie in the support of the measure; moreover, as it easily follows from Proposition [1.1] below, the support is contained in the algebraic variety of
\( M(n), \) which is the intersection of the zero sets of the polynomials arising from column dependence relations in \( M(n); \) that is,

\[
V \equiv V(M(n)) \equiv V_\beta : = \bigcap_{p \in \mathcal{P}_n, \hat{p} \in \text{ker} \ M(n)} Z(p),
\]

where \( Z(p) := \{(x, y) \in \mathbb{R}^2 : p(x, y) = 0\}. \)

**Proposition 1.1.** \([2, \text{Proposition 3.1}]\)**Suppose \( \mu \) is a representing measure for \( \beta. \) Then for \( p \in \mathcal{P}_n, \)

\[
\text{supp } \mu \subseteq Z(p) \iff p(X, Y) = 0.
\]

Thus \( \text{supp } \mu \subseteq V \) and, together with \([3, (1.7)]\), we establish the **variety condition:** if \( r := \text{rank } M(n) \) and \( v := \text{card } V, \) then \( r \leq \text{card supp } \mu \leq v. \) Moreover, in \([2, \text{Corollary 3.4}]\), it is shown that the presence of a measure for \( \beta \) implies

\[
f, g, fg \in \mathcal{P}_n, f(X, Y) = 0 \Rightarrow (fg)(X, Y) = 0.
\]

When \([3]\) holds, \( \beta \) (or \( M(n)(\beta) \)) is said to be **recursively generated.**

Since recursiveness is in general not sufficient for the existence of a representing measure, one considers stronger conditions. The first one is called **weak consistency;** \( \beta \) is said to be **weakly consistent** if the following property holds:

\[
p \in \mathcal{P}_n, \ p|_V \equiv 0 \Rightarrow p(X, Y) = 0.
\]

Indeed, if \( \beta \) has a representing measure \( \mu, \) then the moment sequence must be weakly consistent. For, if \( p \in \mathcal{P}_n \) and \( p|_V \equiv 0, \) then \( p|_{\text{supp } \mu} \equiv 0 \) because \( \text{supp } \mu \subseteq V. \) From Proposition 1.1, we conclude that \( p(X, Y) = 0. \) Similarly, we can show that weakly consistency implies the recursiveness of \( M(n)(\beta). \)

Next, we define an even stronger notion that is the key for the main result of this note; \( \beta \) is said to be **consistent** if the following holds:

\[
p \in \mathcal{P}_n, \ p|_V \equiv 0 \Rightarrow \Lambda(p) = 0.
\]

It is easy to see that consistency is a necessary condition for the existence of a measure; moreover, \([6, \text{Lemma 2.3}]\) shows that consistency is fairly strong. Consistency alone helps establish the existence of an interpolating linear functional, as a linear combination of point masses (with some densities possibly negative). Thus, naturally, the next question arose in \([6]\):

**Suppose** \( M(n)(\beta) \) **is positive and singular. If** \( \beta \) **satisfies the variety condition and is consistent, does** \( \beta \) **admit a representing measure?**

The answer turns out to be negative \([9, \text{Example 3.2}]\): there exists a consistent real moment matrix \( M(3), \) with only one column relation \( (Y = X^3), \) which admits no representing measure. As a result, all necessary conditions introduced so far are not sufficient for general truncated moment problems. In \([9, \text{Example 3.2}]\) the algebraic variety is infinite; this type of example illustrates that a moment problem with infinite algebraic variety is, generally speaking, more difficult to solve, an aspect one should keep in mind.
In [6], R. Curto, L. Fialkow and M. Möller initiated the study of extremal moment problems; that is, the case when \( r := \text{rank} \mathcal{M}(n)(\beta) \) and \( v := \text{card} \mathcal{V}_\beta \) satisfy \( r = v \). The main result in [6] follows,

**Theorem 1.2.** For \( \beta \equiv \beta^{(2n)} \) extremal, i.e., \( r = v \), the following are equivalent:

(i) \( \beta \) has a representing measure;

(ii) \( \beta \) has a unique representing measure, which is \( \text{rank} \mathcal{M}(n) \)-atomic;

(iii) \( \mathcal{M}(n) \) is positive semidefinite and \( \beta \) is consistent.

For the special case of the column relation \( Y = X^3 \), a detailed study can be found in [6]; moreover, a complete solution appears in [9]. To briefly summarize the main results of this case, observe first that such a bivariate sextic truncated moment problem allows only two extremal cases: \( r = v = 7 \) and \( r = v = 8 \) (see Table 1 in Section 3). For the former case, it was proved in [6, Section 4] that positivity and recursiveness are sufficient for the existence of representing measures. On the other hand, when \( r = v = 8 \), consistency is required.

Since all the aforementioned conditions do not solve higher order truncated moment problems, a new notion must be discovered; the first one came in [9], in which a solution of \( \mathcal{M}(n)(\beta) \), for any \( n \geq 1 \), satisfying \( Y = X^3 \) was presented with a numerical condition \( \beta_{1,2n-1} > \psi(\beta) \) (where \( \psi(\beta) \) is a quantity dependent on the moments), together with positivity and the variety condition. This type of numerical condition was never needed in solving quadratic and quartic moment problems, but it was somewhat naturally expected as part of the solution of higher order moment problems.

Our main results in subsequent sections will confirm that numerical conditions play an important role in solving truncated moment problems. Our solutions require new cubics or quartics whose zero sets contain the original algebraic variety, together with cubics arising from the column dependence of the moment matrix. For these new polynomials, we need to verify consistency; it is this verification that will bring a new type of numerical condition.

We briefly pause to remind the reader that there exists an equivalence between bivariate real moments problems and one-variate complex moment problems [4, Proposition 1.12]. Thus, in what follows we freely switch between real moment matrices \( \mathcal{M}(n) \) with columns \( 1, X, Y, X^2, \ldots \) and complex moment matrices \( M(n) \) with columns \( 1, Z, \bar{Z}, Z^2, \ldots \).

In this note, our focus is on the bivariate moment problem, with associated \( \mathcal{M}(3) \) with submatrix \( \mathcal{M}(2) \) positive and invertible, and with a finite algebraic variety. We examine extremal truncated real moment problems with cubic column relations. In [7], we discussed a general case of complex sextic moment problems with a cubic harmonic column relation, \( Z^3 = itZ + u\bar{Z} \) (\( t, u \in \mathbb{R} \)). In that paper, we showed that the polynomial has zeros symmetrically located, for certain values of \( t \) and \( u \). Indeed, this problem turns out to be extremal and a solution was discovered by checking consistency of the moment matrix after establishing a representation theorem of polynomials vanishing on the algebraic variety \( \mathcal{V} \), namely \( \mathcal{I}_\mathcal{V} \).
In Sections 4 and 5, sextic moment problems with more general cubic column relations in real form will be considered; we will focus on the extremal cases.

For the case of harmonic polynomials of the form \( Z^3 = itZ + u \bar{Z} \) \((u, t \in \mathbb{R})\), a representation theorem of polynomials vanishing on the algebraic variety (which consists of 7 points) is achieved by dimensional analysis between a quotient space of complex polynomials and a higher dimensional complex space \([7]\); for more general cases, the Division Algorithm from algebraic geometry will be used instead. Conceptually, the set \( \mathcal{I}_V \) behaves like an ideal and is generated by polynomials from the column relations, plus a few other polynomials obtained from solving Vandermonde equations.

In this paper we focus on the use of the Division Algorithm as a means of identifying a small collection of polynomials for which the Consistency Property must be verified. This explicit listing of just a few polynomials is useful in concrete situations, since it reduces the calculations needed to prove the existence of a representing measure. On the other hand, we should also keep in mind the general strategy in \([8]\), esp. Proposition 3.6 and Remark 3.7, in which L. Fialkow presents a general test for consistency in the case of a finite algebraic variety, and when the points of the variety are known. Thus, we wish to make the reader aware that our approach is not necessarily unique, from the point of view of determining solubility from the concrete knowledge of the algebraic variety. We emphasize the Division Algorithm, but a different approach could be developed using large Vandermonde matrices and a single matrix-vector equation \( Ax = b \), following the conceptual ideas in \([8]\).

2. The Division Algorithm for Multivariable Polynomials

In this paper, we settle all remaining cases of the extremal sextic moment problem, via an application of the Division Algorithm in real algebraic geometry. The algorithm, which follows, involves polynomials in several indeterminates.

**Theorem 2.1.** (Division Algorithm \([1]\)) Fix a monomial order \( > \) on \( \mathbb{Z}_+^n \), and let \( F = (f_1, \ldots, f_s) \) be an ordered s-tuple of polynomials in \( \mathbb{R}[x_1, \ldots, x_n] \). Then every \( f \in \mathbb{R}[x_1, \ldots, x_n] \) can be written as

\[
f = a_1 f_1 + \cdots + a_s f_s + r,
\]

where \( a_i, r \in \mathbb{R}[x_1, \ldots, x_n] \), and either \( r = 0 \) or \( r \) is a linear combination of monomials with coefficients in \( \mathbb{R} \), none of which is divisible by any leading terms of \( f_1, \ldots, f_s \). We call \( r \) a remainder of \( f \) on division by \( F \). Furthermore, if \( a_i f_i \neq 0 \), then we have

\[
\text{multideg}(f) \geq \text{multideg}(a_i f_i).
\]

We shall use the Division Algorithm to prove a structure theorem for polynomials vanishing on the algebraic variety of \( \mathcal{M}(3) \). Although not necessary to solve the truncated moment problem, we note that one significant
difference between the one-dimensional and multi-dimensional versions of the Division Algorithm lies in the fact that a remainder might not be unique in the latter case. Thus, the Division Algorithm might be regarded as an imperfect generalization of the traditional (one-variable) version. However, this situation can be fixed through the so-called Gröebner basis. For further study on this topic, the reader is referred to [1, Section 2.3].

3. Extremal Sextic Moment Problems

To date, the most concrete solution of the truncated moment problem consists of building a sequence of moment matrix extensions which eventually renders a flat moment matrix. (A moment matrix $\mathcal{M}(n)$ is said to be flat if $\operatorname{rank} \mathcal{M}(n) = \operatorname{rank} \mathcal{M}(n-1)$. In principle, one should be able to estimate the smallest integer $k$ satisfying $\operatorname{rank} \mathcal{M}(n+k) = \operatorname{rank} \mathcal{M}(n+k+1)$. However, for sextic or higher order moment problems, the process does not work very well because it requires too many parameters; this leads to memory overflow when using a software package like Mathematica [10]. The existence criterion in [3, Theorem 1.5] gives an upper bound of the number of extension matrices; it is $k = 2n^2 + 6n + 6$, generally too large for a practical construction; however, the following theorem made a significant improvement, in the case where the moment sequence has a finite algebraic variety.

**Theorem 3.1.** [8, Theorem 2.1] Suppose $v < \infty$. Then $\beta$ admits a representing measure if and only if $\mathcal{M}(n)(\beta)$ has a positive extension $\mathcal{M}(n+v-r+1)$ satisfying $\operatorname{rank} \mathcal{M}(n+v-r+1) \leq \operatorname{card} \mathcal{V}(\mathcal{M}(n+v-r+1))$.

**Corollary 3.2.** Let $\beta$, $n$, $v$ and $r$ be as in Theorem 3.1 and assume that $v = r$. Then $n+v-r+1 = n+1$, so that there exists a representing measure if and only if $\mathcal{M}(n)(\beta)$ has a positive extension $\mathcal{M}(n+1)$ satisfying $\operatorname{rank} \mathcal{M}(n+1) \leq \operatorname{card} \mathcal{V}(\mathcal{M}(n+1))$.

When Corollary 3.2 is applied to the extremal case ($r = v$) of the sextic moment problem ($n = 3$), it implies that the existence of a representing measure is equivalent to the existence of a moment matrix extension $\mathcal{M}(4)$ such that $\operatorname{rank} \mathcal{M}(4) \leq \operatorname{card} \mathcal{V}(\mathcal{M}(4))$.

Theorem 3.1 states that if a moment sequence admits a representing measure, $\mathcal{M}(n)$ must have an ascending sequence of moment matrix extensions (rank-increasing) with length $k = v-r$. As a result, we can classify all sextic truncated moment problems, as follows: let us consider an ascending sequence of moment matrix extensions

$$
\mathcal{M}(n) \to \mathcal{M}(n+1) \to \mathcal{M}(n+2) \to \cdots
$$

Now denote $r_n := \operatorname{rank} \mathcal{M}(n)$ and $v_n := \operatorname{card} \mathcal{V}(\mathcal{M}(n))$. The variety condition must hold, so we obtain the following chain of inequalities:

$$
r_n \leq r_{n+1} \leq r_{n+2} \leq \cdots \leq v_{n+2} \leq v_{n+1} \leq v_n.
$$
Since truncated moment problems with quadratic column relations are well understood, we may assume, without loss of generality, that our moment matrix $M(3)$ has an invertible $M(2)$ block; that is, we will always assume that $M(2)$ is positive definite. Table 1 depicts a classification of sextic moment problems, in terms of the rank of the moment matrix and the cardinality of its algebraic variety. For the cases with a finite algebraic variety, it shows the maximum length of the extension sequence (see the column labeled Max Extension).

| $r_3$ | $v_3$ | $v_3 - r_3$ | Max Extension | Ex w rep meas | Ex w/o rep meas |
|-------|-------|-------------|---------------|---------------|-----------------|
| 7     | 7     | 0           | $M(4)$ extremal | known         | unknown         |
| 7     | 8     | 1           | $M(5)$         | unknown       | unknown         |
| 7     | 9     | 2           | $M(6)$         | unknown       | unknown         |
| 7     | $\infty$ | N/A         | N/A           | known         | known           |
| 8     | 8     | 0           | $M(4)$ extremal | known         | known           |
| 8     | 9     | 1           | $M(5)$         | known         | known           |
| 8     | $\infty$ | N/A         | N/A           | known         | known           |
| 9     | 9     | 0           | N/A           | impossible    | impossible      |
| 9     | $\infty$ | N/A         | N/A           | known         | known           |
| 10    | $\infty$ | N/A         | N/A           | known         | known           |

Table 1. Classification of sextic moment problems in terms of $r$ and $v$

As noted in Table 1, the case of $r_3 = v_3 = 9$ cannot happen, since the presence of exactly one column relation means that the associated algebraic curve is the algebraic variety, and this immediately means that $v_3$ is infinity.

In this note, we are mostly interested in the extremal cases, but we will also see how some non-extremal cases of $M(n)$ can be treated as extremal moment problems for an extension $M(n + 1)$, after allowing proper new moments. For this, we need two more results from [5].

**Theorem 3.3.** [5, Theorem 2.3] If $M(n) \geq 0$ admits a flat extension $M(n + 1)$ (i.e., $\text{rank } M(n + 1) = \text{rank } M(n)$), then $\text{rank } M(n) = \text{card } V(M(n + 1))$ and $V(M(n + 1))$ forms the support of the unique representing measure $\nu$ for $M(n + 1)$.

**Theorem 3.4.** [5, Theorem 2.4] Assume that $M(n) \geq 0$ admits a flat extension $M(n + 1)$, and let $M(n + 2)$ the subsequent flat extension of $M(n + 1)$. Then $V(M(n + 2)) = V(M(n + 1))$.

Combining Theorems 3.3 and 3.4 we find a necessary condition for the existence of a flat extension:

$r_n = r_{n+1} \implies \left\{ \begin{array}{l} r_n = v_{n+1} \\ v_{n+1} = v_{n+2} \end{array} \right\} \implies r_n = v_{n+1} = v_{n+2}. \quad (6)$

It follows that $r_n = r_{n+1} \implies r_{n+1} = v_{n+1}$, and therefore $M(n + 1)$ must be extremal.
If we now focus on the case $M(3) \geq 0$ with $r_3 = 8$ and $v_3 = 9$ and apply (6), we observe that there exist two feasible cases:

| $r_3$ | $r_4$ | $r_5$ | $v_5$ | $v_4$ | $v_3$ |
|-------|-------|-------|-------|-------|-------|
| 8     | 8     | 8     | 8     | 8     | 9     |
| 8     | 9     | 9     | 9     | 9     | 9     |

Table 2. The cases when $r_3 = 8$ and $v_3 = 9$

In both cases $M(4)$ must be extremal. Consequently, after building $M(4)$ with proper higher order moments, we may resolve the cases by checking consistency. We will take a careful look at extremal extensions $M(4)$ of $M(3)$ in future work. In Sections 4 and 5 below, we dispose of the remaining extremal cases of the sextic moment problem.

4. The Case rank $M(3) = \text{card } V = 7$

Let $\{1, X, Y, X^2, XY, Y^2, X^3, X^2Y, XY^2, Y^3\}$ denote the set of columns in $M(3)$. In the sequel, assume rank $M(3) := r$ and card $V_\beta := v$, and write $V_\beta \equiv \{(x_1, y_1), \cdots, (x_v, y_v)\}$. The generalized Vandermonde matrix associated with $M(3)$ is

$$W := \begin{pmatrix} 1 & x_1 & x_1^2 & x_1y_1 & x_1^2y_1 & x_1y_1^2 & x_1^3 & x_1^2y_1 & x_1y_1^2 & y_1^3 \\ 1 & x_2 & x_2^2 & x_2y_2 & x_2^2y_2 & x_2^3 & x_2^2y_2 & x_2^2y_2 & y_2^3 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
1 & x_v & x_v^2 & x_vy_v & x_v^2y_v & x_v^3 & x_v^2y_v & x_v^2y_v & y_v^3 \end{pmatrix}. \quad (7)$$

Just as we do for the columns of $M(3)$, we will label the columns of $W$ using $1, X, Y, \cdots$. Given a basis $\mathcal{B}$ for the column space of $M(3)$, let $W_\mathcal{B}$ denote the compression of the generalized Vandermonde matrix $W$ to $\mathcal{B}$.

In this section we study the extremal moment problem for a moment matrix $M(3)$ satisfying

$$M(3) \geq 0, M(2) > 0, \text{ and } r = v = 7. \quad (8)$$

Set $V \equiv V_\beta := \{(x_1, y_1), \cdots, (x_v, y_v)\}$. Because of the variety condition and the invertibility of $M(2)$, there is only one linearly independent column amongst $X^3, X^2Y, XY^2$, and $Y^3$. Thus, the monomial basis of the column space $C_{M(3)}$ must be one of the following:

Case 1. $\mathcal{B}_1 := \{1, X, Y, X^2, XY, Y^2, X^3\}$
Case 2. $\mathcal{B}_2 := \{1, X, Y, X^2, XY, Y^2, X^2Y\}$
Case 3. $\mathcal{B}_3 := \{1, X, Y, X^2, XY, Y^2, XY^2\}$
Case 4. $\mathcal{B}_4 := \{1, X, Y, X^2, XY, Y^2, Y^3\}$
Recall that consistency of $\beta$ is a necessary condition for the existence of a representing measure, and it is also sufficient in the extremal case. Thus, the key to the solution of the truncated moment problem is checking consistency of the moment sequence. Weak consistency and a numerical condition about moments solve Case 1, as follows. But first, we recall a useful property of weak consistency.

**Lemma 4.1.** ([6] Lemma 2.7) The following are equivalent for $\beta$ extremal:

i) $\beta$ is weakly consistent;

ii) For any basis $B$ of $C_M(n)$, the Vandermonde matrix $W_B$ is invertible;

iii) There exists a basis $B$ of $C_M(n)$ such that the Vandermonde matrix $W_B$ is invertible.

**Theorem 4.2.** (Case 1) Suppose $M(3)(\beta)$ satisfies (3). Let $B_1$ be a basis for $C_M(3)$. Then $\beta$ has a representing measure if and only if $M(3)$ is weakly consistent and for $0 \leq i + j \leq 2$,

$$\Lambda_{\beta}(x^i y^j(x^4 - a_{00} - a_{10} x - a_{01} y - a_{20} x^2 - a_{11} x y - a_{02} y^2 - a_{30} x^3)) = 0,$$

where $(a_{00}, a_{10}, a_{01}, a_{20}, a_{11}, a_{02}, a_{30})^T = W_{B_1}^{-1}(x_1^4, \ldots, x_7^4)^T$.

**Proof.** Let $q_k(X, Y) = 0$ denote the column relation in the $k$-th column of $M(3)$ for $k = 8, 9, 10$. Since

$$W_{B_1} = \begin{pmatrix}
1 & x_1 & y_1 & x_1^2 & x_1 y_1 & y_1^2 & x_1^3 \\
1 & x_2 & y_2 & x_2^2 & x_2 y_2 & y_2^2 & x_2^3 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
1 & x_7 & y_7 & x_7^2 & x_7 y_7 & y_7^2 & x_7^3
\end{pmatrix}$$

is invertible, there exists a unique polynomial with the leading monomial $x^4$ that vanishes on the variety $V$, say,

$$s(x, y) := x^4 - (a_{00} + a_{10} x + a_{01} y + a_{20} x^2 + a_{11} x y + a_{02} y^2 + a_{30} x^3),$$

where $(a_{00}, a_{10}, a_{01}, a_{20}, a_{11}, a_{02}, a_{30})^T = W_{B_1}^{-1}(x_1^4, \ldots, x_7^4)^T$.

Set $I := \{p \in P_6 : p|_V \equiv 0\}$. Applying the Division Algorithm (Theorem 2.1), any $p \in I$ can be written as

$$p = Aq_8 + Bq_9 + Cq_{10} + Ds + r,$$

where $A, B, C \in P_3, D \in P_2$ and $r(x, y) = c_{00} + c_{10} x + c_{01} y + c_{20} x^2 + c_{11} x y + c_{02} y^2 + c_{30} x^3$ for some $c_{00}, \ldots, c_{02}, c_{30} \in \mathbb{R}$.

We now claim that $I = \{ f q_8 + gq_9 + hq_{10} + qs : f, g, h \in P_3, q \in P_2 \}$ by showing $r(x, y) \equiv 0$. Note that since $p$ vanishes on $V$, so does $r$, which leads to the following linear system:

$$W_{B_1} \begin{pmatrix} c_{00} & c_{10} & c_{01} & c_{20} & c_{11} & c_{02} & c_{30} \end{pmatrix}^T = \begin{pmatrix} 0 & \cdots & 0 \end{pmatrix}^T.$$

The matrix in the left-hand side is invertible, so we know $c_{00} = c_{10} = c_{01} = c_{20} = c_{11} = c_{02} = c_{30} = 0$, which means $r(x, y) \equiv 0$. 

Consequently, $\beta$ is consistent if and only if
\[
\begin{align*}
\Lambda_\beta(x^iy^jq_k(x,y)) &= 0 \quad (0 \leq i + j \leq 3; \ k = 8, 9, 10); \\
\Lambda_\beta(x^iy^us(x,y)) &= 0 \quad (0 \leq i + j \leq 3; \ k = 7, 9, 10); \\
\end{align*}
\]
But both conditions are immediate from (1), the column relations in $\mathcal{M}(3)$, and the hypotheses.

For Case 2, weak consistency, together with positivity and the variety condition, is enough to solve the moment problem; the proof mimics that of Case 1.

**Theorem 4.3.** (Case 2) Suppose $\mathcal{M}(3)(\beta)$ satisfies (8). Let $\mathcal{B}_2$ be a basis for $\mathcal{C}_{\mathcal{M}(3)}$. Then $\beta$ admits a representing measure if and only if $\mathcal{M}(3)$ is weakly consistent.

**Proof.** Let $q_k(X,Y) = 0$ is the column relation in $i$th column for $k = 7, 9, 10$. Set $I := \{p \in \mathcal{P}_6 : p|_{\mathcal{V}} \equiv 0\}$. Due to the Division Algorithm, we may write any $p \in I$ as
\[ p = Ag_7 + Bg_9 + Cq_{10} + r, \]
where $A, B, C \in \mathcal{P}_3$ and $r(x,y) = c_{00} + c_{10}x + c_{01}y + c_{20}x^2 + c_{11}xy + c_{02}y^2 + c_{21}x^2y$ for some $c_{00}, \ldots, c_{02}, c_{21} \in \mathbb{R}$.

Once we establish that $r(x,y) \equiv 0$, we may verify that $I = \{fg_7 + gg_9 + hq_{10} : f, g, h \in \mathcal{P}_3\}$. Note that $p|_{\mathcal{V}} \equiv 0 \implies r|_{\mathcal{V}} \equiv 0$. This argument brings up the following linear system:
\[
W_{\mathcal{B}_2} \begin{pmatrix} c_{00} & c_{10} & c_{01} & c_{20} & c_{11} & c_{02} & c_{21} \end{pmatrix}^T = \begin{pmatrix} 0 & \cdots & 0 \end{pmatrix}^T.
\]
The invertibility of $W_{\mathcal{B}_2}$ implies that $c_{00} = c_{10} = c_{01} = c_{20} = c_{11} = c_{02} = c_{21} = 0$, i.e., $r(x,y) \equiv 0$. Therefore, we need only three polynomials attained from column relations in $\mathcal{M}(3)$ to check consistency of $\beta$. The test is straightforward, since $\beta$ is consistent if and only if
\[
\Lambda_\beta(x^iy^jq_k(x,y)) = 0 \quad (0 \leq i + j \leq 3; \ k = 7, 9, 10),
\]
which is inherent in $\mathcal{M}(3)$, using (1). This completes the proof. □

In order to solve Case 3, we can use the same approach as in Case 2; the proof is omitted.

**Theorem 4.4.** (Case 3) Suppose $\mathcal{M}(3)(\beta)$ satisfies (8). Let $\mathcal{B}_3$ be a basis for $\mathcal{C}_{\mathcal{M}(3)}$. Then $\beta$ admits a representing measure if and only if $\mathcal{M}(3)$ is weakly consistent.

**Remark 4.5.** (Case 4) It is straightforward to see that Case 4 reduces to Case 1 via the invariance of moment problems under degree-one transformations ([4, Proposition 1.7]). Indeed, it suffices to consider the degree-one transformation that interchanges $X$ and $Y$. □
5. The Case \( \text{rank } \mathcal{M}(3) = \text{card } \mathcal{V} = 8 \)

In this section we discuss the other extremal moment problem for a moment matrix \( \mathcal{M}(3) \) satisfying

\[
\mathcal{M}(3) \geq 0, \mathcal{M}(2) > 0, \text{ and } r = v = 8.
\]  

Write \( \mathcal{V} \equiv \mathcal{V}_\beta := \{ (x_1, y_1), \cdots , (x_8, y_8) \} \). Since we assumed the invertibility of the minor block \( \mathcal{M}(2) \) and \( \text{rank } \mathcal{M}(3) = 8 \), there are two linearly independent columns among \( X^3, X^2Y, XY^2, \) and \( Y^3 \). Thus, there are six natural choices for bases of \( \mathcal{C}_{\mathcal{M}(3)} \):

Case 1. \( \mathcal{B}_1 := \{ 1, X, Y, X^2, XY, Y^2, X^3, X^2Y \} \)

Case 2. \( \mathcal{B}_2 := \{ 1, X, Y, X^2, XY, Y^2, X^3, XY^2 \} \)

Case 3. \( \mathcal{B}_3 := \{ 1, X, Y, X^2, XY, Y^2, X^3, Y^3 \} \)

Case 4. \( \mathcal{B}_4 := \{ 1, X, Y, X^2, XY, Y^2, X^2Y, XY^2 \} \)

Case 5. \( \mathcal{B}_5 := \{ 1, X, Y, X^2, XY, Y^2, X^2Y, Y^3 \} \)

Case 6. \( \mathcal{B}_6 := \{ 1, X, Y, X^2, XY, Y^2, XY^2, Y^3 \} \)

Again, the problem will be solved once we show that the moment sequence is consistent. The proofs are very similar to those in the previous section, but we need to find another polynomial vanishing on the algebraic variety. Also, we can reduce some cases to a subcase of another via degree-one transformations, that is, interchanging \( X \) and \( Y \). We immediately obtain the following two Claims.

Claim 1. Case 6 is a subcase of Case 1.

Claim 2. Case 5 is a subcase of Case 2.

Thus, it suffices to focus attention on the first four cases and present their solutions. The detailed proofs are omitted. Instead, we present in the next paragraph a general sketch of a typical proof; with this, the interested reader will be able to fill out the remaining details.

Obviously, the “only if” parts of the proofs of Theorems 5.1, 5.2, 5.3 and 5.4 are trivial, so we work on the converses. To establish consistency, we need to show that the Riesz functional is zero for any polynomial vanishing on the algebraic variety, of degree less than or equal to 6. Thus, it is essential to construct a representation of such polynomials, which is done by the Division Algorithm. The representing sets contain at most 4 polynomials, two of which come from column relations in \( \mathcal{M}(3) \) and the other two polynomials (which are quartic) are found using the invertibility of the appropriate compression of the generalized Vandermonde matrix (equivalently, by the weak consistency of \( \beta \)). Multiplying polynomials in the representing set by suitable monomials, we can check that the Riesz functional is zero for higher order polynomials.
Theorem 5.1. (Case 1) Suppose $\mathcal{M}(3)(\beta)$ satisfies [10]. Let $\mathfrak{B}_1$ be a basis for $\mathcal{C}_{\mathcal{M}(3)}$. Then $\beta$ has a representing measure if and only if $\mathcal{M}(3)$ is weakly consistent and for $0 \leq i + j \leq 2$,

$$
\Lambda_\beta(x^iy^j(x^4 - a_0 - a_1x - a_2y - a_3x^2 - a_4xy - a_5y^2 - a_6x^3 - a_7x^2y)) = 0
$$

and

$$
\Lambda_\beta(x^iy^j(x^3y - b_0 - b_1x - b_2y - b_3x^2 - b_4xy - b_5y^2 - b_6x^3 - b_7x^2y)) = 0,
$$

where $(a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7)^T = W_{\mathfrak{B}_1}^{-1}(x_1^4, \ldots, x_8^4)^T$

and $(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7)^T = W_{\mathfrak{B}_1}^{-1}(x_1^2y_1, \ldots, x_8^2y_8)^T$.

Theorem 5.2. (Case 2) Suppose $\mathcal{M}(3)(\beta)$ satisfies [10]. Let $\mathfrak{B}_2$ be a basis for $\mathcal{C}_{\mathcal{M}(3)}$. Then $\beta$ has a representing measure if and only if $\mathcal{M}(3)$ is weakly consistent and for $0 \leq i + j \leq 2$,

$$
\Lambda_\beta(x^iy^j(x^4 - a_0 - a_1x - a_2y - a_3x^2 - a_4xy - a_5y^2 - a_6x^3 - a_7x^2y)) = 0,
$$

where $(a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7)^T = W_{\mathfrak{B}_2}^{-1}(x_1^4, \ldots, x_8^4)^T$.

Theorem 5.3. (Case 3) Suppose $\mathcal{M}(3)(\beta)$ satisfies [10]. Let $\mathfrak{B}_3$ be a basis for $\mathcal{C}_{\mathcal{M}(3)}$. Then $\beta$ has a representing measure if and only if $\mathcal{M}(3)$ is weakly consistent and for $0 \leq i + j \leq 2$,

$$
\Lambda_\beta(x^iy^j(x^4 - a_0 - a_1x - a_2y - a_3x^2 - a_4xy - a_5y^2 - a_6x^3 - a_7x^2y)) = 0
$$

and

$$
\Lambda_\beta(x^iy^j(y^4 - b_0 - b_1x - b_2y - b_3x^2 - b_4xy - b_5y^2 - b_6x^3 - b_7x^2y)) = 0,
$$

where $(a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7)^T = W_{\mathfrak{B}_3}^{-1}(x_1^4, \ldots, x_8^4)^T$

and $(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7)^T = W_{\mathfrak{B}_3}^{-1}(y_1^4, \ldots, y_8^4)^T$.

Theorem 5.4. (Case 4) Suppose $\mathcal{M}(3)(\beta)$ satisfies [10]. Let $\mathfrak{B}_4$ be a basis for $\mathcal{C}_{\mathcal{M}(3)}$. Then $\beta$ has a representing measure if and only if $\mathcal{M}(3)$ is weakly consistent and for $0 \leq i + j \leq 2$,

$$
\Lambda_\beta(x^iy^j(x^2y^2 - a_0 - a_1x - a_2y - a_3x^2 - a_4xy - a_5y^2 - a_6x^3 - a_7x^2y)) = 0,
$$

where $(a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7)^T = W_{\mathfrak{B}_4}^{-1}(x_1^2y_1^2, \ldots, x_8^2y_8^2)^T$.

(Observe that in Theorem 5.4, we are essentially representing the column $X^2Y^2$ in terms of columns of lower degrees.) In [6], the authors provided an example of $\mathcal{M}(3)$ satisfying $Y = X^3$ in $\mathcal{C}_{\mathcal{M}(3)}$ and $r = v = 8$, which is weakly consistent but not consistent. Consequently, $\beta^{(6)}$ has no representing measure. They actually obtained a rather general class of examples; here, we will content ourselves with focusing on one specific case, to show that the numerical conditions about moments in the our main theorems are essential.
Example 5.5. (cf. [6, Theorem 5.2]) Consider $\beta^{(6)}$ with following moments;

\[
\begin{align*}
\beta_{00} & := 14, & \beta_{10} & := \frac{7}{16}, & \beta_{01} & := -\frac{67}{16}, & \beta_{02} & := \frac{18195}{64}, \\
\beta_{20} & := -\frac{67}{8}, & \beta_{11} & := -\frac{1935}{32}, & \beta_{12} & := -\frac{43115}{128}, & \beta_{03} & := -\frac{926695}{512}, \\
\beta_{30} & := -\frac{1055}{16}, & \beta_{21} & := \frac{18195}{64}, & \beta_{22} & := \frac{336151}{256}, \\
\beta_{40} & := \frac{6407195}{1024}, & \beta_{31} & := -\frac{43115}{128}, & \beta_{32} & := -\frac{926695}{512}, \\
\beta_{50} & := -\frac{1935}{32}, & \beta_{41} & := -\frac{43115}{128}, & \beta_{42} & := -\frac{8894873563}{32768}, \\
\beta_{23} & := -\frac{19736547}{2048}, & \beta_{14} & := -\frac{41917615}{8192}, & \beta_{51} & := -\frac{336151}{256}, \\
\beta_{60} & := \frac{18195}{64}, & \beta_{15} & := \frac{49568350247}{65536}, & \beta_{06} & := -\frac{1006568996907}{262144}.
\end{align*}
\]

After building $\mathcal{M}(3)(\beta)$, we see that there are two column relations

\[
f(X, Y) := X^3 - Y = 0
\]

and

\[
g(X, Y) := Y^3 - 3X + \frac{3}{4}Y + 13X^2 - \frac{65}{4}XY + \frac{13}{4}Y^2 - 12X^3 + 22X^2Y - \frac{35}{4}XY^2 = 0
\]

in $\mathcal{C}_{\mathcal{M}(3)}$. This moment matrix satisfies (10) with the basis $\mathfrak{B}_4$ as in Case 4. A calculation shows that the algebraic variety is

\[
\mathcal{V} = \{(0, 0), (-2, -3), (2, 8), (1, 1), \left(-1 - \sqrt{13}/2, -5 - 2\sqrt{13}\right), \left(-1 + \sqrt{13}/2, -5 + 2\sqrt{13}\right), (-1, -1), (1/2, 1/8)\}
\]

(see [6, Section 6]). In order to apply Theorem 5.4 we need to find the new polynomial, denoted as $h(x, y)$, vanishing on $\mathcal{V}$ by using the compression of the generalized Vandermonde matrix. Theorem 6.2 in [6] states that the above mentioned moment matrix $\mathcal{M}(3)$ is positive semidefinite, recursively generated, and extremal, but does not admit a representing measure (because it is not consistent). Using our Theorem 5.4 we can proceed as follows. First,

\[
h(x, y) = x^4 + 6x - \frac{11}{2}y - 14x^2 + \frac{43}{2}xy - \frac{17}{2}y^2 - x^2y + \frac{1}{2}xy^2.
\]

Next, we evaluate the Riesz functional acting on $h$:

\[
\Lambda_\beta(h) = \beta_{40} + 6\beta_{10} - \frac{11}{2}\beta_{01} - 14\beta_{20} + \frac{43}{2}\beta_{11} - \frac{17}{2}\beta_{02} - \beta_{21} + \frac{1}{2}\beta_{12}
\]

\[
= -\frac{320081}{256},
\]

which is different from zero. That is, even though $h$ vanishes on $\mathcal{V}$, its Riesz functional is not zero. We have therefore verified that $\beta$ admits no representing measure. \qed
Acknowledgment. Example 5.5 and portions of the proofs of some results in this paper were obtained using calculations with the software tool Mathematica [10].
