Synthesizing Multiple Boolean Functions using Interpolation on a Single Proof

Georg Hofferek\(^1\) Ashutosh Gupta\(^2\) Bettina Könighofer\(^1\) Jie-Hong Roland Jiang\(^3\) Roderick Bloem\(^1\)
\(^1\)Graz University of Technology, Austria \(^2\)IST Austria \(^3\)National Taiwan University

Abstract—It is often difficult to correctly implement a Boolean controller for a complex system, especially when concurrency is involved. Yet, it may be easy to formally specify a controller. For instance, for a pipelined processor it suffices to state that the visible behavior of the pipelined system should be identical to a non-pipelined reference system (Burch-Dill paradigm). We present a novel procedure to efficiently synthesize multiple Boolean control signals from a specification given as a quantified first-order formula (with a specific quantifier structure). Our approach uses uninterpreted functions to abstract details of the design. We construct an unsatisfiable SMT formula from the given specification. Then, from just one proof of unsatisfiability, we use a variant of Craig interpolation to compute multiple coordinated interpolants that implement the Boolean control signals. Our method avoids iterative learning and back-substitution of the control functions. We applied our approach to synthesize a controller for a simple two-stage pipelined processor, and present first experimental results.

I. INTRODUCTION

Some program parts are easier to write than others. Freedom of deadlocks, for instance, is trivial to specify but not to implement. These parts lend themselves to synthesis, in which a difficult part of the program is written automatically. This approach has been followed in program sketching [19], [21], [20], in lock synthesis [24], and in synthesis using templates [9], [22], [23].

In this paper, we consider systems that have multiple unimplemented Boolean control signals. The systems that we will consider may not be entirely Boolean. We will consider systems with uninterpreted functions, but our method extends to systems with linear arithmetic. For example, consider a microprocessor. Following Burch and Dill [5], we assume that a reference implementation of the datapath is available. Constructing a pipelined processor is not trivial, as it involves implementing control logic signals that control the hazards arising from concurrency in the pipeline. Correctness of the pipelined processor is stated as equivalence with the reference implementation. In this setting, we can avoid the complexity of the datapath (which is the same in the two implementations) by abstracting it away using uninterpreted functions. Where Burch and Dill verify that the implementation of the control signals is correct, we construct a correct implementation automatically. This problem was previously addressed in [12]. We improve over that paper by directly encoding the problem into SMT, thus avoiding BDDs, and by avoiding backsubstitution in case multiple functions are synthesized.

Our approach is also applicable to synthesis of conditions in (loop-free) programs. As noted in [9], synthesizing loop-free programs can be a building block of full program synthesis. Prior work [19] presented various techniques to deal with finite loops. Those techniques are also applicable in our framework.

To synthesize a single missing signal, we can introduce a fresh uninitialized Boolean variable \(c\). We can express the specification as a logical formula \(\forall I \exists c \forall O. \Phi(I, c, O)\), which states that, for each input \(I\), there exists a value of \(c\) such that each output \(O\) of the function is correct. Here, \(I\) and \(O\) can come from non-Boolean domains. If an implementation is possible, the formula is valid and a witness function for \(c\) is an implementation of the missing signal.

Following [13], we can generate a witness using interpolation. In this paper, we generalize this approach by allowing \(n \geq 1\) missing components to be synthesized simultaneously. This leads us to a formula of the form \(\forall I \exists c_1 \ldots c_n \forall O. \Phi(I, c_1 \ldots c_n, O)\). We use an SMT solver to prove a related formula unsatisfiable and use interpolation [17] to obtain the desired witness functions. The first contribution of this paper is to extend prior work [13] beyond the propositional level, and consider formulas expressed in the theory of uninterpreted functions and equality. As a second contribution, we propose a new technique, called \(n\)-interpolation, which corresponds to simultaneously computing \(n\) coordinated interpolants from just one proof of unsatisfiability. Like the interpolation procedures of [11], [14], we need a “colorable” proof, which we produce by transforming a standard proof from an SMT solver.

Our algorithm avoids the iterative interpolant computation described in [13], where interpolants are iteratively substituted into the formula. As the iterative approach needs one SMT solver call per witness function, and interpolants may grow dramatically over the iterations, this computation may be costly and may yield large interpolants. A similar back-substitution method is also used in [2] for GR(1) synthesis and in [15] for functional synthesis. Our new method requires the expansion of the the (Boolean) existential quantifier, increasing the size of the formula exponentially (w.r.t. the number of control signals). Note, however, that previous approaches [13] have the same limitation.

This research was supported by the European Commission through project DIAMOND (FP7-2009-IST-4-248613), the Austrian Science Fund (FWF) through projects RISE (S11406-N23) and QUAINIT (I774-N23), and ERC Advanced Grant QUAREM (Quantitative Reactive Modeling). This paper originally appeared in FM CAD 2013, http://www.cs.utexas.edu/users/burma/ FMCAD/FMCAD13/index.shtml. This version includes an appendix that is missing in the conference version.
The following grammar defines the syntax of the formulas in Equality simultaneously and in a coordinate method computes both interpolants.

This problem is normally solved for instance, we may choose carrying non-zero signed integers, and also two output bit-vectors \( o_1 \) and \( o_2 \) carrying signed integers. The block \( \text{neg} \) flips the sign of its input. The outputs are controlled by two bits, \( c_1 \) and \( c_2 \). The controller of \( c_1 \) and \( c_2 \) is not implemented. Suppose the specification of the incomplete design states that the signs of the two outputs must be different. Formally, the specification is

\[
\forall i_1, i_2. \exists c_1, c_2. \forall o_1, o_2. ((c_1 \land o_1 = i_1 \lor \neg c_1 \land o_1 = \neg \text{pos}(i_1)) \land (c_2 \lor o_2 = i_2 \lor \neg c_2 \lor o_2 = \neg \text{pos}(i_2)) \to (\text{pos}(o_1) \leftrightarrow \neg \text{pos}(o_2)),
\]

where the predicate \( \text{pos} \) returns \( T \) iff its parameter is positive. We can compute witness functions for \( c_1 \) and \( c_2 \) using \( n \)-interpolation.\(^1\) Our method returns witness functions \( c_1 = \text{pos}(i_1) \) and \( c_2 = \neg \text{pos}(i_2) \). (Other functions are also possible.)

Note that computing two interpolants independently may not work. For instance, we may choose \( c_1 = T \) or we can take \( c_2 = T \), but we cannot choose \( c_1 = c_2 = T \). This problem is normally solved by substituting one solution before the next is computed, but our method computes both interpolants simultaneously and in a coordinated way.

### III. Preliminaries

#### A. Uninterpreted Functions and Arrays

We consider the Theory of Uninterpreted Functions and Equality \( T_U \). We have variables \( x \in X \) from an uninterpreted domain, Boolean variables \( b \in B \), uninterpreted function symbols \( f \in F \), and uninterpreted predicate symbols \( P \in P \). The following grammar defines the syntax of the formulas in \( T_U \).

\[
\begin{align*}
\text{terms} & \ni t ::= x \mid f(t, \ldots, t), \\
\text{atoms} & \ni a ::= b \mid P(t, \ldots, t) \mid t = t, \\
\text{formulas} & \ni \phi ::= a \mid \neg \phi \mid \phi \lor \phi.
\end{align*}
\]

Let \( \phi_1 \land \phi_2 \) be short for \( \neg (\neg \phi_1 \lor \neg \phi_2) \). Let \( a \neq b \) be short for \( \neg (a = b) \). Let \( T = \phi \lor \neg \phi \), let \( F = \neg T \), and let \( B = \{ T, F \} \).

A literal is an atom or its negation. Let \( l \) be a literal. If \( l = \neg a \) then let \( \neg l = a \). A clause is a set of literals, interpreted as the disjunction. The empty clause \( \emptyset \) denotes \( F \). A conjunctive formula is the negation of a clause. A CNF formula is a set of clauses. A CNF formula is interpreted as the conjunction of its clauses. Since any formula can be converted into a CNF formula, we will assume that all the formulas in this paper are CNF formulas. Let \( \phi \) and \( \psi \) be CNF formulas/clauses/literals.

\(^1\)We must add the axiom \((\text{pos}(i_1) \oplus \text{pos}(\neg \text{pos}(i_1))) \land (\text{pos}(i_2) \oplus \neg \text{pos}(\neg \text{pos}(i_2)))\).
(partitioned into the root node \( r \), the set of internal nodes \( N_I \), and the set of leaf nodes \( N_L \)), and \( E \subseteq N \times N \) is the set of (directed) edges. Every \( n \in N \) is labeled with the name of a proof rule \( \text{rule}(n) \) and a clause \( \text{clause}(n) \). The graph has to fulfill the following properties:

1. \( \text{clause}(r) = \emptyset \).
2. For all \( n \in N_L \), \( \text{clause}(n) \) is either a clause from \( \phi \) (if \( \text{rule}(n) = \text{HYP} \)) or a theory-tautology clause (if \( \text{rule}(n) = \text{AXI} \)).
3. The nodes in \( N_L \) whose clauses are theory-tautology clauses can be ordered in such a way that for each such node each implicant literal either occurs in \( \phi \), or is an implied literals of the tautology clause of a preceeding node (according to the order).\(^2\)
4. The root has no incoming edges, the leaves have no outgoing edges, and all nodes in \( n \in N \setminus N_L \) have exactly 2 outgoing edges, pointing to nodes \( n_1, n_2 \), with \( n_1 \neq n_2 \). Using \( \text{clause}(n_1) \) and \( \text{clause}(n_2) \) as premises and \( \text{clause}(n) \) as conclusion must yield a valid instance of proof rule \( \text{rule}(n) \).

We used the VERIT SMT solver [3], which provides proofs that conform to these requirements.

C. Transitivity-Congruence Chains

Given a set \( A \) of atoms, we can use the well-known congruence-closure algorithm to construct a congruence graph [8] according to the following definition.

**Definition 3 (Congruence Graph).** A congruence graph over a set \( A \) of atoms is a graph which has terms as its nodes. Each edge is labeled either with an equality justification, which is an equality atom from \( A \) that equates the terms connected by the edge, or with a congruence justification. A congruence justification can only be used when the terms connected by the edge are both instances of \( f(a_1, \ldots, a_k) \) and \( f(b_1, \ldots, b_k) \) of the same uninterpreted function \( f \). In this case, the congruence justification is a set of \( k \) paths in the graph connecting the \( a_i \) and \( b_i \) respectively, not using the edge which they label.

**Definition 4 (Transitivity-Congruence Chain).** A transitivity-congruence chain \( \pi = (a \rightarrow b) \) is a path in a congruence graph that connects terms \( a \) and \( b \). Let \( \text{Lits}(\pi) \) be the set of literals of the path, which is defined as the union of the literals of all edges on the path. The literal of an edge labeled with an equality justification \( p \) is the set \( \{p\} \). The set of literals of an edge labeled with a congruence justification with paths \( \pi_i \) is recursively defined as \( \bigcup \text{Lits}(\pi_i) \).

**Theorem 1.** The conjunction of the literals of a transitivity-congruence chain \( (a \rightarrow b) \) implies \( a = b \) within \( \mathcal{T}_0 \). I.e., \((\forall c \in \text{Lits}(a \rightarrow b) \neg c) \lor (a = b)\) is a theory-tautology clause.

D. Craig Interpolation

Let \( \phi \) and \( \psi \) be CNF formulas such that \( \phi \land \psi \) is unsatisfiable. The algorithm presented in [17] for computing an interpolant between \( \phi \) and \( \psi \) needs a proof of unsatisfiability of \( \phi \lor \psi \). By annotating this proof with the partial interpolants, the algorithm computes the interpolant. In this paper, we present slightly different annotation rules to compute interpolants, which are results of mixing ideas from [14], [18].

**Definition 5 (Partial interpolant).** Let \( C \) be a clause such that \( \phi \land \psi \rightarrow C \). A formula \( I \) is a partial interpolant for \( C \) between \( \phi \) and \( \psi \) if \( \phi \rightarrow C \mid \phi \lor I \), and \( \psi \rightarrow C \mid \psi \lor \neg I \), and \( I \leq \phi \), and \( I \leq \psi \). If \( I \) is a partial interpolant for \( C \), then \( I \) is an interpolant between \( \phi \) and \( \psi \).

In Figure 3, we present interpolating proof rules. In an unsatisfiability proof of \( \phi \land \psi \), these rules annotate (in square brackets) each conclusion with a partial interpolant for the conclusion. Rules IT\(HYP-\phi \) and IT\(HYP-\psi \) are used at leaf nodes that have clauses from \( \phi \) and \( \psi \) respectively. Rules IT\(AXI-\phi \) and IT\(AXI-\psi \) are used for leaves with theory-tautology clauses, whose symbols are a subset of the symbols in \( \phi \) and \( \psi \) respectively. Note that these rules assert that the unsatisfiability proof of \( \phi \land \psi \) is colorable.

**Definition 6 (Colorable Proof).** A proof of unsatisfiability of \( \phi \land \psi \) is colorable if for every leaf \( n_L \) of the proof \( \text{Symb}(\text{clause}(n_L)) \subseteq \text{Symb}(\phi) \) or \( \text{Symb}(\text{clause}(n_L)) \subseteq \text{Symb}(\psi) \).

In Section V, we will present an algorithm that transforms a proof into a colorable proof. Due to this assumption we can easily find corresponding partial interpolants for theory-tautology clauses, which are either \( \top \) or \( \bot \). For internal proof nodes, we follow Pudlák’s interpolation system [18]. The annotation of the root node (with the empty clause) is the interpolant between \( \phi \) and \( \psi \). See [7] for a proof of correctness of the annotating proof rules.

IV. CONTROLLER SYNTHESIS

A. Overview

Following [12], we assume that synthesis problems are given as formulas of the form

\[
\forall \vec{i} \exists \vec{c} \forall o. \Phi(\vec{i}, \vec{c}, o),
\]

where \( \vec{c} \) is a vector of Boolean variables and \( \Phi \) is a formula over theory \( \mathcal{T}_0 \). Let \( \vec{c} = (c_1, \ldots, c_n) \). Each \( c_i \) represents a missing if-condition in a program or a one-bit control signal in a hardware design. Witness functions for the existentially quantified variables in Eq. (1) are implementations of the missing components. Therefore, the synthesis problem is equivalent
to finding such witness functions. I.e., find \((f_1(\bar{i}), \ldots, f_n(\bar{i}))\)

such that \(\forall \bar{i} \forall \bar{o}. \Phi(\bar{i}, (f_1(\bar{i}), \ldots, f_n(\bar{i})), \bar{o})\) holds true.

We compute the witness functions through the following steps:

1. Expand the existential quantifier and negate the formula \(\Phi\) to obtain an unsatisfiable formula \(\phi\) (Sec. IV-B).
2. Obtain a proof of unsatisfiability from an SMT solver.
3. Transform the proof into a colorable, local-first proof (Sec. V).
4. Perform \(n\)-interpolation on the transformed proof. The elements of the \(n\)-interpolant correspond to the witness functions (Sec. IV-B).

We will first introduce the notion of \(n\)-interpolation and show how it is used to find witness functions in Section IV-B. Subsequently, we will show how to transform a proof of unsatisfiability so that it is suitable for \(n\)-interpolation in Section V.

B. Finding Witness Functions through Interpolation

Jiang et al. [13] show how to compute a witness function in Eq. (1) using interpolation if \(c\) contains a single Boolean \(c\). In this case, Eq. (1) reduces to \(\forall \bar{i} \exists c \forall \bar{o}. \Phi(\bar{i}, c, \bar{o})\).

After expanding the existential quantifier by instantiating the above formula for both Boolean values of \(c\) and renaming \(\bar{o}\) in each instantiation, we obtain the equivalent formula \(\forall \bar{i} \forall \bar{o}_g, \bar{o}_r, \Phi(\bar{i}, (c, \bar{o}_g) \lor (c, \bar{o}_r, \bar{o}_r))\). Since all the quantifiers are universal, the disjunction is valid. Therefore, its negation \(\neg\Phi(\bar{i}, (c, \bar{o}_g) \lor (c, \bar{o}_r, \bar{o}_r))\) is unsatisfiable. The interpolant between the two conjuncts is the witness function for variable \(c\).

Theorem 2. The interpolant between \(\neg\Phi(\bar{i}, (c, \bar{o}_g) \lor (c, \bar{o}_r, \bar{o}_r))\) is the witness function for \(c\). (For a proof, see Appendix B.)

We now extend this idea to compute witness functions when \(\bar{c}\) is a vector of Booleans \((c_1, \ldots, c_n)\). Let \(\mathbb{B}^n\) denote the set of vectors of length \(n\) containing \(Fs\) and \(Ts\). For vector \(w \in \mathbb{B}^n\), let \(w^j\) be the Boolean value in \(w\) at index \(j\). Since \(\bar{c}\) is a Boolean vector, we can expand the existential quantifier for \(c\) in Eq. (1) by enumerating the finitely many possible values of \(\bar{c}\) to obtain \(\forall \bar{i} \forall \bar{o}_g, \bar{o}_r, \Phi(\bar{i}, (w^j, \bar{o}_g))\). By dropping the quantifiers and renaming \(\bar{o}\) accordingly, we obtain \(\forall \bar{o}_g, \Phi(\bar{i}, w, \bar{o}_g)\). It is valid iff Eq. (1) is valid. Let \(\phi\) denote its negation \(\neg\Phi(\bar{i}, w, \bar{o}_g)\), which is unsatisfiable. Let \(\phi_w\) denote \(\neg\Phi(\bar{i}, w, \bar{o}_g)\). We will call the \(\phi_w\)s the \(2^n\) partitions of \(\phi\). We will learn a vector of coordinated interpolants from an unsatisfiability proof of \(\phi\). These interpolant formulas will be witness functions for \(c\). Since \(\phi_{\bar{s}}\)s are obtained by only renaming variables, the shared symbols between any two partitions are equal.

Definition 7 (Global and Local Symbols). Symbols in the set \(G = \bigcap_{w \in \mathbb{B}^n} \text{Symb}(\phi_w)\) are called global symbols. All other symbols are called local (w.r.t. the one partition in which they occur).

Let \(\bar{T}\) be a vector of formulas \((I_1, \ldots, I_n)\). Let \(\oplus\) be the exclusive-or (xor) operator. For a word \(w \in \mathbb{B}^n\), let \(T_j = \bar{T} \oplus w\) if for each \(j \in 1..n, I_j = I_j \oplus w_j\). Let \(\bigvee T\) be short

The interpolant between \(\Phi(\bar{i}, (w^j, \bar{o}_g))\) and \(\neg\Phi(\bar{i}, (w^j, \bar{o}_r, \bar{o}_r))\) is the witness function for \(c\). (For a proof, see Appendix B.)

C. Computing \(n\)-interpolants

In Figure 4, we present the proof rules for \(n\)-interpolants. These rules annotate each conclusion of a proof step with an \(n\)-partial interpolant for the conclusion w.r.t. the \(\phi_w\)s. These annotation rules require two properties of the proof. First, it needs to be colorable. Second, it needs to be local-first.

Definition 9 (Local-first Proof). A proof of unsatisfiability is local-first, if for every resolution node with a local pivot both its premises are derived from the same partition.

The rule MHYP annotates the derived clause \(C\) with \(w\) if \(C\) appears in partition \(\phi_w\). Similarly, the rule MAXI annotates theory-tautology clause \(C\) with \(w\) if \(C \leq \phi_w\). Rules MRES and MRES-G annotate resolution steps. MRES-G is only applicable if the pivot is local and follows Pudlák’s interpolation system \(n\) times. MRES-G is only applicable if both premises are annotated with the same \(n\)-partial interpolant and this \(n\)-partial interpolant is an element of \(\mathbb{B}^n\). Due to the local-first assumption on proofs, these rules will always be able to annotate a proof.

Theorem 4. Annotations in the rules in Figure 4 are \(n\)-partial interpolants for the respective conclusions w.r.t. the \(\phi_w\)s. (For a proof see Appendix D.)

Since the \(n\)-interpolant is always quantifier free, we can easily convert it into an implementation. To create a circuit for one element of the \(n\)-interpolant, we create, for every resolution node with a global pivot, a multiplexer that has the pivot at its selector input. The other inputs connect to the outputs of the multiplexers corresponding to the child nodes. For leaf nodes and resolution nodes with local pivots, we use the constants \(T, F\), depending on which partition the node belongs to. The output of the multiplexer corresponding to the root node is the final witness function. Note that, unless
we apply logical simplifications, the circuits for all witness functions all have the same multiplexer tree and differ only in the constants at the leaves of this tree.

Also note that due to the local-first property, all nodes that are derived from a single partition are annotated with the same \( n \)-partial interpolant. Thus, we can disregard such local sub-trees, by iteratively converting nodes that have only descendants from one partition into leaves. This does not affect the outcome of the interpolation procedure.

The local-first property is actually needed to correctly compute witness functions using Pudlák’s interpolation system. In Appendix A, we illustrate this observation with an example. Also note that McMillan’s interpolation [17] system does not produce correct witness functions even with the local-first property.

V. Algorithms for Proof Transformation

Our interpolation procedure requires proofs to be colorable and local-first. These properties are not guaranteed by efficient modern SMT solvers. In this section we will show how to transform a proof conforming to Def. 2 into one that is colorable and local-first. Our proof transformation works in three steps. First, we will remove any non-colorable literals from the proof. Second, we will split any non-colorable theory-tautology clauses. This gives us a colorable proof. In the third step, we will reorder resolution steps to obtain the local-first property [7]. For ease of presentation, we will assume that the proof is a tree (instead of a DAG). The method extends to proofs in DAG form.

A. Removing Non-Colorable Literals

**Definition 10** (Colorable and Non-Colorable Literals). A literal \( a \) is colorable with respect to a partition \( \phi_{\alpha} \) (\( w \)-colorable) iff \( a \not\preceq \phi_{\alpha} \). A literal that is not \( w \)-colorable for any partition \( w \) is called non-colorable.

Note that global literals are \( w \)-colorable for every \( w \). By definition, the formula \( \phi \) is free of non-colorable literals (equalities and predicate instances). Thus, the only way through which non-colorable literals can be introduced into the proof are theory-tautology clauses.

We search the proof for a theory-tautology clause that introduces a non-colorable literal \( a \) and has only colorable literals as implying literals. We call this proof node the **defining node** \( n_d \). At least one such leaf must exist. We remove this non-colorable literal from the proof as follows. Starting from \( n_d \), we traverse the proof towards the root, until we find a node, which we call **resolving node** \( n_r \), whose clause does not contain the literal \( a \) any more. Since the root node does not contain any literals, such a node always exists. Let \( n_a \) and \( n_{-a} \) be the premises of \( n_r \), respectively, depending on which phase of literal \( a \) their clause contains. From \( n_{-a} \), we traverse the proof towards the leaves along nodes that contain the literal \( \neg a \). Note that any leaf that we reach in this way must be labeled with a theory-tautology clause, as clauses from \( \phi \) cannot contain the non-colorable literal \( \neg a \). Note that \( \neg a \) is among the implicant literals of such a leaf node’s clause. I.e., such nodes use the literal to imply another one. We will therefore call such a node a **using node** \( n_u \). We update clause \( n_u \), by removing \( \neg a \) and adding the implying literals of clause \( n_d \) instead.

It is easy to see that this does not affect clause \( n_u \)’s property of being a theory-tautology clause. Suppose clause \( n_d \) is \( \neg x_1 \lor \ldots \lor \neg x_k \lor a \). Then \( \bigwedge_{i=1}^{k} x_i \rightarrow a \). By reversing the implication we obtain \( \neg a \rightarrow \bigvee_{i=1}^{k} \neg x_i \). Therefore, replacing \( \neg a \) with the disjunction of the implicant literals of clause \( n_d \) in clause \( n_u \) is sound.

To keep the proof internally consistent, we have to do the same replacement on all the nodes on the path between \( n_u \) and \( n_r \). The node \( n_r \) itself is not changed, as clause \( n_r \) does not contain the non-colorable literal \( \neg a \) any more. I.e., the last node that is updated is the node \( n_{-a} \).

Now we have to distinguish two cases. The first case is that node \( n_a \) still contains all of the implying literals of \( n_d \). In this case, clause \( n_r \) = clause \( n_{-a} \), where \( n_{-a} \) is the updated node \( n_{-a} \). Thus, we use \( n_{-a} \) instead of \( n_r \) in \( n_r \)’s parent node. In the second case, some of the implying literals of clause \( n_d \) have already been resolved on the path from \( n_d \) to \( n_r \). In that case clause \( n_{-a} \) contains literals that do not occur in clause \( n_r \). Let \( x_l \) be one such literal. We search the path from \( n_d \) to \( n_r \) for the node that uses \( x_l \) as a pivot. Its premise that is not on the path from \( n_d \) to \( n_r \) contains \( \neg x_l \). We use this node and the node \( n_{-a} \) as premises for a new resolution node with \( x_l \) as pivot. Note that this resolution may introduce more literals that do not appear in clause \( n_r \) any more. However, just as with \( x_l \), any such literal must have been resolved somewhere on the path between \( n_d \) and \( n_r \). Thus, we repeat this procedure, replicating the resolution steps that took place between \( n_d \) and \( n_r \), until we get a node whose clause is identical to clause \( n_r \). This node can then be used instead of \( n_r \) in \( n_r \)’s parent node. Finally, we remove all nodes that are now unreachable from the proof.

**Example 1.** An illustrative example of this procedure is shown in Figure 5.

We repeat this procedure for all leaves with a non-colorable implied literal and (all) colorable implying literals. Note that one application of this procedure may convert a node where a non-colorable literal was implied by at least one other non-colorable literal into a node where the implied non-colorable literal is now implied only by colorable literals. Nevertheless this procedure terminates, as the number of leaves with non-colorable implied literals decreases with every iteration. Each iteration removes (at least) one such leaf from the proof and no new leaves are introduced.

**Theorem 5.** Upon termination of this procedure, the proof does not contain any non-colorable literals.

B. Splitting Non-Colorable Theory-Tautology Clauses

After removing all non-colorable literals, the proof may still contain non-colorable theory-tautology clauses, i.e., theory-tautology clauses that contain local literals from more than one partition. We split such leaves into several new theory-tautology clauses, each containing only \( w \)-colorable literals,
and, via resolution, obtain a (now internal) node with the same clause as the original non-colorable theory-tautology clause. Note that internal nodes with non-colorable clauses are not a problem for our interpolation procedure, but leaves with non-colorable clauses are. We will show how to split a non-colorable theory-tautology clause with an implied equality literal. This procedure can be trivially extended to implied literals that are uninterpreted predicate instances.

Using the implying literals of the theory-tautology clause (converted to their positive phase), we create a congruence graph (cf. Def. 3). Since the implying literals and the implied literal form a theory tautology, this congruence graph is guaranteed to contain a path between the two terms equated by the implied literal. We use breadth-first search to find the shortest such transitivity-congruence chain (Def. 4). The chain will be the basis for splitting the non-colorable theory tautology. First, we need to make all edges in the chain colorable. A colorable edge is an edge for which there is a w such that all the edge’s literals are w-colorable. Edges with an equality justification already are colorable, as we assumed that no non-colorable literals occur in the theory-tautology clause. Edges with congruence justifications, however, may still be non-colorable. I.e., the two terms they connect might belong to different partitions, and/or some of the paths that prove equality for the function parameters might span over more than one partition. Fuchs et al. [8] have shown how to recursively make all edges in a chain colorable by introducing global intermediate terms for non-colorable edges. We will illustrate this procedure with a simple example, and refer to [8] for details.

Example 2. Suppose we have the two local terms \( f(l_1) \) and \( f(l_2) \), where \( l_1, l_2 \) are from two different partitions, and a global term \( g \). (See Fig. 6.) A possible (non-colorable) congruence justification for \( f(l_1) = f(l_2) \) could be given as \( l_1 = g, g = l_2 \). The edge between \( f(l_1) \) and \( f(l_2) \) is now split into two (colorable) parts: \( f(l_1) = f(g) \), with justification \( l_1 = g \), and \( f(g) = f(l_2) \), with justification \( g = l_2 \). Note that \( f(g) \) is a new term that (possibly) did not appear in the congruence graph before. Since we assumed that there are no non-colorable equality justifications in our graph, such a global intermediate term must always exist. It should be clear how to extend this procedure to \( n \)-ary functions.

Note that in a colorable chain, every edge either connects two terms of the same partition, or a global term and a local term. In other words, terms from different partitions are separated by at least one global term between them. We now divide the whole chain into (overlapping) segments, so that each segment uses only \( w \)-colorable symbols. The global terms that separate symbols with different colors are part of both segments. Let’s assume for the moment that the chain starts and ends with a global term. We will show how to deal with local terms at the beginning/end of the chain later. For ease of presentation, also assume that the chain consists of only two segments. An extension to chains with more segments can be done by recursion. We take the first segment of the chain (from start to the global term that is at the border to the next segment), plus a new “shortcut” literal that states equality between the last term of the first segment and the last term of the entire chain, and use them as implying literals for a new theory-tautology clause. The implied literal of this tautology will be an equality between the first and the last term of the entire chain. Next, we create a theory tautology with the literals of the second segment of the chain. Note that the implied literal of this theory-tautology clause (which occurs in positive phase) is the same as the shortcut literal used in the theory-tautology clause corresponding to the first segment. There, however, it occurred in negative phase. Thus, we can use this literal for resolution between the two clauses. We obtain a node that has all the literals of the entire chain.

Fig. 5. Removing a non-colorable literal. Assume that term indices indicate the number of the partition the term belongs to. Index \( g \) is used for global terms. This example shows how the non-colorable literal \( l_1 = l_2 \), introduced in node \( n_d \), is removed from the proof by replacing its negative occurrences with the (colorable) defining literals \( l_1 \neq l_2 \). Note that in the original proof \( l_1 \neq l_2 \) is already resolved on the path from \( n_d \) to \( n_r \) using node \( n_1 \). This resolution step is replicated in the transformed proof by making a resolution step with nodes \( n_{r,d} \) and \( n_1 \). Since the literal \( x_2 = y_2 \) introduced into \( n_{r,d} \) also occurs in the original \( n_r \), and also the second defining literal \( z_2 \neq l_2 \) occurs in \( n_r \), no further resolution steps are necessary. The conclusions of \( n_d \) and \( n_{r,d} \) are identical and \( n_{r,d} \) can be used instead of \( n_r \) in \( n_r \)’s parent.

Fig. 6. Splitting a non-colorable transitivity-congruence chain by introducing global intermediate terms.
as implying literals, and an equality between start term and end term of the chain as the implied literal. I.e., this new internal node has the same conclusion as the non-colorable theory-tautology clause from which we started.

In case the start/end of the chain is not a local term, we first deal with the sub-chain from the first to the last global term, as described above. Note that if both start and end of the chain are local terms, they have to belong to the same partition, because otherwise the implied literal would be non-colorable. We create a theory-tautology clause with the local literals from the start/end of the chain, and one shortcut literal that equates the first and last global term. This literal can be used for resolution with the implied literal of the node obtained in the previous step.

In summary, this procedure replaces all leaves that have non-colorable theory-tautology clauses with subtrees whose leaves are all colorable theory-tautology clauses, and whose root is labeled with the same clause as the original non-colorable leaf.

**Example 3.** Fig. 7 shows how to split the non-colorable theory-tautology clause \((a_1 \neq b_1 \lor b_1 \neq c_g \lor c_g \neq d_2 \lor d_2 \neq e_2 \lor e_2 \neq f_g \lor f_g \neq k_3 \lor k_3 \neq k_g \lor k_g \neq l_1 \lor a_1 = l_1)\).

**Theorem 6.** After applying the above procedure to all leaves with non-colorable theory-tautology clauses, the proof is colorable.

### C. Obtaining a local-first proof

To obtain a local-first proof, we traverse the proof in topological order. Each time we encounter a resolution step that has a global pivot and we have seen local pivots among its ancestors then we apply one of the two transformation rules presented in Figure 8 depending on the matching pattern. These two transformation rules are the standard pivot reordering rules from [7]. Note that these rules assume that the proof is redundancy free, which can be achieved by the algorithms presented in [10]. After repeated application of these transformation rules, we can move the resolutions with local pivots towards the leaves of the proof until we don’t have any global pivot among its descendants.

**Theorem 7.** After exhaustive application of this transformation, we obtain a colorable, local-first proof.

### VI. EXPERIMENTAL RESULTS

We have implemented a prototype to evaluate our interpolation-based synthesis approach. We read the formula \(\Phi\) corresponding to our synthesis problem (Eq. 1) from a file in SMT-LIB format [1]. As a first step, our tool performs several

---

**Fig. 7. Splitting theory tautology clauses.** Suppose we have created the transitivity-congruence chain \((a_1 \Rightarrow b_1 \Rightarrow c_2 \Rightarrow d_2 \Rightarrow e_2 \Rightarrow f_2 \Rightarrow h_3 \Rightarrow k_2 \Rightarrow l_1)\) from a theory-tautology clause, where all the edges are colorable. The number in the index indicates the partition of the respective term, with \(g\) being used for global terms. First, we consider only the part from the first to the last global term, \(g\), which corresponds to all links of the original chain which we have not dealt with already, and a “shortcut” over the part we have already considered: \((a_1 \Rightarrow b_1 \Rightarrow c_2 \Rightarrow k_2 \Rightarrow l_1)\). Note that this is also a colorable theory-tautology clause. By resolution over \(n_3\) and \(n_4\) we obtain \(n_5\), whose clause is identical to the theory-tautology clause from which we started.

**Fig. 9.** A simple microprocessor with a 2-stage pipeline.

transformations on the input formula (reduction of arrays to uninterpreted functions [4], expansion of the existential quantifier to obtain the partitions, renaming of \(\bar{a}\)-variables in each partition, negation to obtain \(\phi\), before giving it to the VERIT solver. Second, we apply the proof transformations described in Section V to the proof we obtain from VERIT. Third, we compute the witness functions as the \(n\)-interpolants w.r.t. the partitions of \(\phi\).

We have checked all results using Z3 [6], by showing that \(\neg \Phi(i, (f_1(i), \ldots, f_n(i)), \bar{a})\) is unsatisfiable.

We used our tool on several small examples and also tried one non-trivial example which we explain in more detail. In Fig. 9 we show a simple (fictitious) microprocessor with a 2-stage pipeline. MEM represents the main memory. We assume that the value at address 0 is hardwired to 0. I.e., reading from address 0 always yields value 0. The blocks inst-of, op-a-of, op-b-of, and addr-of represent combinational functions that decode a memory word. The block incr increments the program counter (PC). The block is-BEQZ is a predicate that checks whether an instruction is a branch instruction. The design has two pipeline-related control signals for which we would like to synthesize an implementation. Signal \(c_1\) causes a value in the pipeline to be forwarded and signal \(c_2\) squashes the instruction that is currently decoded and executed in the first pipeline stage. This might be necessary due to speculative execution based on a “branch-not-taken assumption”. The implementation of these control signals is not as simple as it
As a second comparison, we tried to reduce the (quantified) number of nodes in proof (local sub-trees have been converted to leaves).

Table I summarizes our experimental results. The bench-

| Name  | Ctrl time [s] | # leaves to clean | # leaves to split | Reorder- Time [ms] | Proof size |
|-------|---------------|------------------|------------------|--------------------|------------|
| const | 2              | 0.6              | 0 / 6            | 42                 | 19 / 1     |
| illu02| 1.1            | 1                | 1 / 65           | 83                 | 205 / 12   |
| illu03| 5.0            | 8                | 81 / 338         | 487                | 467 / 22   |
| illu04| 4              | 8.0              | 3 / 242          | 532                | 951 / 75   |
| illu05| 5              | 12.8             | 10 / 413         | 589                | 1588 / 78  |
| illu06| 6              | 237.0            | 9 / 1970         | 1820               | 4691 / 370 |
| illu07| 7              | 150.0            | 14 / 1443        | 2860               | 6824 / 555 |
| illu08| 8              | 1270.0           | 20 / 23450       | 4980               | 17524 / 1023 |
| pipe  | 1.6            | 1.6              | 3 / 70           | 129                | 285 / 22   |
| proc  | 2.81           | 3 + 3            | 61 / 1014        | 1770               | 5221 / 1042 |

Table I

Experimental results. Columns: (1) Name; (2) Number of control signals; (3) Total synthesis time including checking the results; (4) Number of leaves with theory-tautology clauses that define a new non-colorable literal (Number of such leaves at the start of the cleaning procedure + Number of leaves introduced (and subsequently removed) by the procedure); (5) Number of leaves to be split because they contain literals from more than one partition. (Number after "/" is total number of leaves in proof at beginning of split procedure; (6) Time to reorder the proof to be local-first; (7) Number of nodes in proof from veriT / Size of the transformed proof for interpolation (local sub-trees have been converted to leaves).

might seem at first glance. For example, the seemingly trivial solution of setting \( c_1 = T \) whenever PC equals the address register is not correct. For example, if \( PC = 0 \), forwarding should not be done.\(^6\) By taking out the blue parts in Fig. 9 we obtain the non-pipelined reference implementation which we used to formulate a Burch-Dill-style equivalence criterion \([5]\). The resulting formula was used as a specification for synthesis.

Table I summarizes our experimental results. The benchmark "const" is a simple example with 2 control signals that allows for constants as valid solutions. "illu02" is the example presented in Section II; "illu03" to "illu08" are scaled-up versions of "illu02", with increased numbers of inputs and control signals. "pipe" is the simple pipeline example that was used in [12], "proc" is the pipelined processor shown in Fig. 9 and described above. All experiments were performed on an Intel Nehalem CPU with 3.4 GHz.

Note that using our new method we have reduced the synthesis time of "pipe" from 14 hours [12] to 1.6 seconds. As a second comparison, we tried to reduce the (quantified) input formula of "proc" to a QBF problem (using the transformations outlined in [12]) and run DEPQBF \([16]\) on it. After approximately one hour, DEPQBF exhausted all 192 GB of main memory and terminated without a result.

VII. CONCLUSION

Hofferek and Bloem [12] have shown that uninterpreted functions are an efficient way to abstract away unnecessary details in controller synthesis problems. By using interpolation in \( \mathcal{T}_U \), we avoid the costly reduction to propositional logic, thus unleashing the full potential of the approach presented in [12]. Furthermore, by introducing the concept of \( \eta \)-interpolation, we also avoid the iterative construction which requires several calls to the SMT solver and back-substitution. The \( \eta \)-interpolation approach improves synthesis times by several orders of magnitude, compared to previous methods [12], rendering it applicable to real-world problems, such as pipelined microprocessors. We have also shown that a naive transformation to QBF is not a feasible option.

Appendix

A. Why local-first?

Example 4. Let us consider the formula
\[ \forall a, b \exists c_1, c_2 \forall I . \Phi(a, b, c_1, c_2, I), \]
where
\[ \Phi(a, b, c_1, c_2, I) := (c_1 \land \neg c_2 \land \neg a) \lor (\neg c_1 \land c_2 \land \neg b) \lor (c_1 \land c_2 \land (l \land \neg a) \lor (l \land b)), \]
and all variables are Boolean. We will compute witness functions for \( c_1 \) and \( c_2 \) in terms of \( a \) and \( b \). After instantiating for all values of \( c_1 \) and \( c_2 \), and negating the instantiated formulas, we obtain
\[ \phi_{FF} := T \quad \phi_{FT} := b \]
\[ \phi_{TF} := a \quad \phi_{TT} := (l \lor \neg a) \land (\neg l \lor \neg b) \]
\[ \phi := \phi_{FF} \land \phi_{FT} \land \phi_{TF} \land \phi_{TT}. \]
The global variables are \( G = \{a, b\} \). Since \( l \) appears only in \( \phi_{TT} \), we decided not to rename it. Let's suppose the following is the proof of unsatisfiability of \( \phi \) produced by an SMT solver:

\[ \begin{array}{c|c|c}
\text{RES} & a & l \lor \neg a \\
& b & \neg l \lor \neg b \\
\hline
l & l[T] & l[T] \\
a[T] & b[F] & \neg l[b[T] \\
\hline
\emptyset & l[a] & \emptyset[a] \\
\hline
\end{array} \]

Similarly, if we compute an interpolant between \( \phi_{FF} \land \phi_{FT} \land \phi_{TF} \) and \( \phi_{TT} \) by applying the original interpolation rules on the proof then we obtain the following annotated proof:

\[ \begin{array}{c|c|c}
\text{RES} & a & l \lor \neg a \\
& b & \neg l \lor \neg b \\
\hline
l[T] & l[T] & l[T] \\
a[F] & b[T] & \neg l[b[T] \\
\hline
\emptyset & l[a] & \emptyset[a] \\
\hline
\end{array} \]

From the above annotations, we learn \( I_{c_1} = a \) and \( I_{c_2} = b \), which are not valid witness functions if they are used together because \( \Phi(a, b, a, b, l) \) is not a valid formula. Let's consider the following unsatisfiability proof, which satisfies the local-first property.

\[ \begin{array}{c|c|c}
\text{RES} & l \lor \neg a & \neg l \lor \neg b \\
& -a \lor \neg b & a \\
\hline
\neg a & b & \emptyset \\
\hline
\end{array} \]

If we annotate this proof with our annotation rules, we obtain
\[ \begin{array}{c|c|c}
\text{RES} & -a & l \lor \neg b \\
& \neg b & a[T,F] \\
\hline
a[(T,T)] & a[(T,F)] & a[(T,F)] \\
\hline
\neg a & \neg b[(T,T)] & \emptyset[(b, \neg b \lor a)] \\
\hline
\end{array} \]

From the above annotations, we learn \( I_{c_1} = b \) and \( I_{c_1} = \neg b \lor a \), which are valid witness functions.

B. Proof of Theorem 2

Proof: Since \( \overline{\Phi} \) and \( \overline{\Phi} \) do not appear in both \( -\Phi(i, F, \overline{\Phi}) \) and \( -\Phi(i, T, \overline{\Phi}) \), only \( i \) can appear in the interpolant between the formulas. Let \( I(i) \) be the interpolant computed via our interpolation procedure. Due to the definition of interpolation, \( -\Phi(i, F, \overline{\Phi}) \rightarrow I(i) \) and \( -\Phi(i, T, \overline{\Phi}) \rightarrow -I(i) \). After reversing the implications, we obtain \( -I(i) \rightarrow \Phi(i, F, \overline{\Phi}) \) and \( I(i) \rightarrow \Phi(i, T, \overline{\Phi}) \). After reintroducing the quantifiers for \( \overline{\Phi} \) we obtain \( \neg I(i) \rightarrow \forall \overline{\Phi}(i, F, \overline{\Phi}) \) and \( I(i) \rightarrow \forall \overline{\Phi}(i, T, \overline{\Phi}) \). Therefore, \( \forall i. \forall \overline{\Phi}(i, \overline{\Phi}(i, \overline{\Phi})) \). Hence, \( I(i) \) is a witness function for \( c \).

C. Proof of Theorem 3

Proof: Since for each \( w, \overline{\Phi}(w) \) only appear in \( \Phi(w) \), they cannot be in \( G \) and only \( i \) are in \( G \). Let \( T(i) = (I_1(i), \ldots, I_n(i)) \) be an \( n \)-interpolant w.r.t. \( \Phi(w) \). Due to the definition of \( n \)-interpolation, for each \( w \in \mathbb{B}^n \),
\[ \Phi(w) \rightarrow \bigvee T(i) \oplus w. \]

After reversing the implications and expanding the definition of \( \Phi(w) \), we obtain
\[ \bigwedge \neg T(i) \oplus w \rightarrow \Phi(i, w, \overline{\Phi}(w)). \]

After reintroducing the quantifiers for \( \overline{\Phi} \) we obtain
\[ \bigwedge \neg T(i) \rightarrow \forall \overline{\Phi}(i, w, \overline{\Phi}(w)). \]

Therefore, \( \forall i. w = T(i) \rightarrow \forall \overline{\Phi}(i, w, \overline{\Phi}(w)) \). Hence, \( \forall i. \forall \overline{\Phi}(i, T(i), \overline{\Phi}(i, \overline{\Phi}(i, \overline{\Phi}))). \]

Hence for each \( j \in 1..n \), \( I_j(i) \) is a witness function for \( c_j \).

D. Proof of Theorem 4

Proof: We will prove the theorem using induction over the proof structure. All annotations must satisfy the conditions of \( n \)-partial interpolant. Note that \( \bigvee w \oplus w = F \) and if \( w' \neq w \) then \( \bigvee w' \oplus w = T \).

Base cases:

\textbf{M Hyp}: Let \( w' = w \). Since \( C \in \Phi(w) \), \( C|_{w'} = C \). Therefore, \( C|_w \lor w \lor w' = C \). Since \( C \in \Phi(w) \), \( \Phi(w) \rightarrow C \). Therefore, \( \Phi(w) \rightarrow C \lor w \lor w' \). Now, let \( w' \neq w \). Therefore, \( C|_w \lor \bigvee w \lor w' = T \). Therefore, \( \Phi(w) \rightarrow C|_w \lor \bigvee w \lor w' \). \( \Phi(w) \) is a theory tautology clause, \( \Phi(w) \rightarrow C|_w \lor \bigvee w \lor w' \). For \( w' \neq w \), same as previous rule. \( w \neq G \).

\textbf{MaxI}: Let \( w' = w \). Since \( C \in \Phi(w) \), \( C|_{w'} = C \). Therefore, \( C|_w \lor \bigvee w \lor w' \). \( C \) is a theory tautology clause, \( \Phi(w) \rightarrow C|_w \lor \bigvee w \lor w' \). \( \Phi(w) \) is a theory tautology clause, \( \Phi(w) \rightarrow C|_w \lor \bigvee w \lor w' \). \( \Phi(w) \) is a theory tautology clause, \( \Phi(w) \rightarrow C|_w \lor \bigvee w \lor w' \). \( \Phi(w) \) is a theory tautology clause, \( \Phi(w) \rightarrow C|_w \lor \bigvee w \lor w' \). 

Inductive cases: We assume that the annotations of the premises are \( n \)-partial interpolant.

\textbf{M Res}: Let \( w' = w \). Since
\[ \phi_{w'} \rightarrow a \lor C \lor \bigvee w \lor w' \] and \( \phi_{w'} \rightarrow \neg a \lor D \lor \bigvee w \lor w' \),
we can easily show \( \phi_{w'} \rightarrow C \lor D \lor \bigvee w \lor w' \). For \( w' \neq w \), same as previous rule. \( w \neq G \).

\textbf{M Res-G}: Due to the definition of \( n \)-partial interpolants, for each \( w \in \mathbb{B}^n \)
\[ \phi_{w'} \rightarrow a \lor C|_w \lor \bigvee T^C \lor w \] and \( \phi_{w} \rightarrow \neg a \lor D|_w \lor \bigvee T^D \lor w \).
After taking conjunction of the two implications, we obtain
\[ \phi_w \rightarrow (a \lor C|_w \lor \bigvee T^C \oplus w) \land (\neg a \lor D|_w \lor \bigvee T^D \oplus w). \]

After expanding the definition of or-of-xor of vectors and moving \( a \) and \( \neg a \) inside the vector disjunction, we obtain
\[ \phi_w \rightarrow (C|_w \lor \bigvee_{j=0}^n (a \lor I_C^j \oplus w_j)) \land (D|_w \lor \bigvee_{j=0}^n (\neg a \lor I_D^j \oplus w_j)). \]

Using \((a \lor b) \land (c \lor d) \rightarrow (a \lor c) \lor (b \land d)\), we obtain
\[ \phi_w \rightarrow (C \lor D)|_w \lor ((a \lor I_C^j \oplus w_j) \land (\neg a \lor I_D^j \oplus w_j)). \]

After moving out the disjunctions, we obtain
\[ \phi_w \rightarrow (C \lor D)|_w \lor \bigvee_{j=0}^n ((a \lor I_C^j \oplus w_j) \land (\neg a \lor I_D^j \oplus w_j)). \]

After moving out the \( \oplus \) operator, we obtain
\[ \phi_w \rightarrow (C \lor D)|_w \lor \bigvee_{j=0}^n ((a \lor I_C^j) \land (\neg a \lor I_D^j)) \oplus w_j. \]

Since \( \{a, T^C, T^D\} \preceq G \), symbols in the annotation of the conclusion are within \( G \). \hfill \blacksquare
