Habitual dislocation of patella is a rare disorder. Sometimes it is associated with angular deformity such as genu valgum. We experienced habitual patella dislocation associated with genu valgum that was treated with corrective osteotomy of distal femur and soft tissue realignment procedure including lateral release and medial reefing.

Key words: Habitual patella dislocation, Genu valgum, Distal femoral osteotomy.

Habitual patellar dislocation is a rare condition where the patella dislocates during flexion and relocates during extension unlike chronic patellar dislocation that occurs during both flexion and extension of the knee, and it usually presents without pain or swelling.

A variety of surgical techniques have been introduced for the treatment of habitual dislocation of the patella with genu valgum. Among them, osteotomy combined with proximal soft tissue realignment procedures including lateral release and medial reefing has been commonly performed. It has been known that significant treatment results can be obtained with combined procedures, not with a single procedure.

We here report a case of habitual dislocation of the patella with genu valgum treated with a corrective osteotomy of the distal femur combined with lateral release and medial reefing.

The clinical and radiological outcomes of the treatment were satisfactory.

Case Report

A 23-year-old man visited our institution due to lateral dislocation of the left knee in flexion and instability that had persisted for 7 years (Fig. 1). The patient had a history of femoral growth plate fracture treated conservatively at 13 years of age. In the physical examination, the apprehension test was positive. In the radiographic examination, the congruence angle, sulcus angle, Q-angle, and Insall-salvati Ratio was 44.17°, 152°, 18°, and 1.15, respectively. The tibiofemoral angle measured from the weight-bearing radiograph was 16°, indicating genu valgum deformity, and hypoplasia of the lateral femoral condyle of the left knee was observed. A skyline view of the knee showed lateral dislocation of the patella. Arthroscopic examination revealed the hypoplasia of the lateral femoral condyle, Outerbridge grade II cartilage damage on the lateral articular surface, and contracture of the lateral retinaculum and vastus lateralis. Patellar dislocation during flexion was confirmed with arthroscopy. A lateral retinacular release and an open-wedge distal femoral varus osteotomy were followed by additional procedures including lateral release and medial reefing because dislocation was still present after the osteotomy. About 2 cm of the medial retinaculum was reefed because it was excessively elongated. When lateral dislocation of the patella in flexion was no longer observed, a bone graft was inserted into the osteotomy site. Gradual flexion exercises were started postoperatively. Complete flexion was obtained at the
3\textsuperscript{rd} postoperative week. Weight bearing was gradually permitted and complete weight bearing was allowed at the 3\textsuperscript{rd} postoperative month.

On the postoperative radiograph, the congruence angle, sulcus angle, Q-angle, and Insall-salvati ratio was 15.75\(^\circ\), 152\(^\circ\), 2.3\(^\circ\), and 1.03, respectively. The tibiofemoral angle was corrected to 4\(^\circ\) of valgus on the weight-bearing radiograph. Dislocation did not recur at 27 months after surgery. No limitation of joint motion was noted. The apprehension test for recurrent dislocation was negative (Fig. 2). The Kujala score\(^1\) was 96, indicating excellent clinical results.

Discussion

The causes of habitual patellar dislocation include contracture and fibrosis of the quadriceps femoris, vastus lateralis, and lateral retinaculum, abnormal iliobifal band attachment, repeated intramuscular injections into the thigh, patella alta due to the abnormal position of an elongated patellar tendon, systemic ligament laxity, dysplastic lateral femoral condyle, and genu valgum\(^2-4\).

A variety of surgical techniques have been introduced for the treatment of habitual dislocation of the patella. However, it has been known that combined procedures, not one single procedure, should be performed to achieve relatively satisfying treatment results.

Hnevovsky et al.\(^4\) attributed habitual patellar dislocation to contracture of the quadriceps femoris and introduced a technique to lengthen the muscle with the use of a lateral retinacular release and quadricepsplasty, which did not bring about complete flexion in their patients. In our patient, genu valgum and lateral femoral condyle hypoplasia following a growth plate fracture were thought as the cause of the dislocation. A quadricepsplasty was considered unnecessary because he had no contracture of the quadriceps femoris. However, lateral retinacular release alone was not sufficient to achieve joint reduction.

Realignment procedures can be performed additionally to reduce the joint. They are broadly classified into proximal and
distal realignment procedures or bone and soft tissue realignment procedures. Proximal soft tissue realignment procedures including lateral release and medial reefing and distal realignment procedures are commonly used in adults. In particular, distal realignment procedures are limited to adult patients with ≥20° of Q-angle because they could result in premature growth plate closure in children with open growth plates.

Proximal realignment is the most effective treatment for reduction of patellar dislocation. However, vastus medialis advancement can cause an increase in pressure on the knee, which eventually results in patellofemoral arthritis. Recently, medial patellofemoral ligament reconstruction using semitendinosus or gracillis tendon is recommended. Although the patient’s medial retinaculum was extensively elongated, it was thick enough to be reeved and sutured. Therefore, a reconstruction using a medial patellofemoral ligament allograft was not considered necessary and the reduction was maintained at the follow-up examination.

Appropriate surgical treatment methods for habitual dislocation of the patella with genu valgum still remain controversial. Gao et al. reported that flexion contracture of the quadriceps muscle was the cause of lateral dislocation of the patella in children and the sustained contracture also resulted in genu valgum. A release of quadriceps femoris contracture can be effective in correcting genu valgum in children who have hypoplasia of the lateral femoral condyle due to growth plate damage. Still, the ideal age for the treatment has yet to be established.

In adults, if genu valgum deformity remains after realignment due to the unstable patella, symptoms may also persist. Coventry reported that femoral supracondylar varus osteotomy should be performed in patients with ≥12° of symptomatic genu valgum or with ≥10° of tilt of the articular surface. Healy et al. recommended to perform corrective osteotomy of the distal femur for ≥15° of genu valgum. Shen et al. suggested proximal soft tissue realignment and distal femoral osteotomy and anteromedial tibial tubercle transfer to treat genu valgum with ≥20° of femorotibial angle. The femorotibial angle was 16° in our patient. Therefore, we thought proximal soft tissue realignment alone was not sufficient to realign the patella and performed a femoral supracondylar osteotomy in addition. Femoral supracondylar osteotomy for genu valgum can be performed using an open or closed technique, but the latter has been associated with postoperative joint stiffness. Considering that the risk of joint stiffness would be high in our patient because of the complex procedures including lateral retinacular release and medial reefing, we used an open osteotomy technique and took care not to damage the joint capsule during surgery.

We believe that clinical improvement of habitual dislocation of the patella can be obtained with correction of soft tissue imbalance and contracture and realignment of the patellofemoral and tibiofemoral joints. In particular, soft tissue procedures should be followed by bony procedures including femoral supracondylar osteotomy in cases of habitual dislocation of the patella with genu valgum.
