Abstract

We consider the Lane–Emden system $\Delta u = v^p$, $\Delta v = u^\theta$ in $\mathbb{R}^N$, and we prove the nonexistence of smooth positive solutions which are stable outside a compact set, for any $p, \theta > 0$ under the Sobolev hyperbola.

Keywords: Lane–Emden system, stable solutions, stability outside a compact set, $m$-biharmonic equation

1. Introduction

Consider the classical Lane–Emden system

$$\Delta u = v^p, \quad \Delta v = u^\theta, \quad u, v > 0 \quad \text{in} \quad \mathbb{R}^N, \quad \text{where} \quad p, \theta > 0. \quad (1.1)$$

There is a famous conjecture who states that: \textit{Let $p, \theta > 0$. If the pair $(p, \theta)$ is subcritical, i.e. if}

$$\frac{1}{p + 1} + \frac{1}{\theta + 1} > \frac{N - 2}{N}, \quad (1.2)$$

\textit{then there is no smooth solution to (1.1).}

The critical curve given by the equality in (1.2) is called the Sobolev hyperbola, which is introduced independently by Mitidieri \cite{11} and Van der Vorst \cite{21}, it plays a crucial role in the analysis of (1.1). It is well known that if $(p, \theta)$ lies on or above the Sobolev hyperbola,
(1.1) admits radial classical solutions (see [12, 18]), and the Lane–Emden conjecture can be restated as the following: there is no smooth solution to (1.1) if the positive pair \((p, \theta)\) lies below the Sobolev critical hyperbola.

The conjecture is proved to be true for radial functions by Mitidieri [12], Serrin–Zou [17]. For the full conjecture, Soupto [20], Mitidieri [12] and Serrin–Zou [18] proved that there is no supersolution to (1.1), if the positive pair \((p, \theta)\) lies below the Sobolev critical hyperbola.

The conjecture is proved to be true for radial functions by Mitidieri [12], Serrin–Zou [17]. For the full conjecture, Soupto [20], Mitidieri [12] and Serrin–Zou [18] proved that there is no supersolution to (1.1), if the positive pair \((p, \theta)\) lies below the Sobolev critical hyperbola.

derived a striking monotonicity formula, which led them to the optimal classification result for solutions stable at infinity, using blow down analysis.

Coming back to the Lane–Emden system (1.1), Chen–Dupaigne–Ghergu [3] studied the stability of radial solutions when \( p, \theta \geq 1 \). They introduced a new critical hyperbola, called the Joseph-Lundgren curve. More precisely, they proved that if \( p, \theta \geq 1 \), then a radial solution of (1.1) is unstable if and only if \( N \leq 10 \), or \( N \geq 11 \) and

\[
\left[ \frac{(N-2)^2 - (\alpha - \beta)^2}{4} \right]^2 < p\theta\alpha\beta(N-2 - \alpha)(N-2 - \beta).
\]

Moreover, Cowan proved in [4] that if \( p, \theta \geq 2 \) and \( N \leq 10 \), there does not exist any stable solution (radial or not) to (1.1). Recently, Hajlaoui–Harrabi–Mtiri [9] established some Liouville theorems for smooth stable solutions of (1.1) with \( p > 1 \), see theorem A below. We mention also the celebrated result of Ramos [16], which states that if \( p, \theta > 1 \) satisfies (1.2), then the system

\[-\Delta u = |v|^{p-1}v, \quad -\Delta v = |u|^{\theta-1}u \quad \text{in } \mathbb{R}^N\]

does not admit any smooth solutions having finite relative Morse index in the sense of Abbondandolo.

In this paper, our motivation are twofold. We want to obtain the classification results for solutions (radial or not) to (1.1) which are just stable at infinity, and we want to handle the case where \( p, \theta \) are allowed to be less than 1. So a natural question is: can we prove the Lane–Emden conjecture with the extra condition that \((u, v)\) is stable at infinity? The answer is affirmative.

**Theorem 1.1.** For any \( p, \theta > 0 \) satisfying (1.2), the system (1.1) has no classical solution stable outside a compact set.

If \( \theta = p \), using Souplet’s comparison result (lemma 2.7 in [19]), we get \( u \equiv v \), so the optimal classification result for solutions stable at infinity was already given by Farina. The
classification is also known for \( \rho \theta \leq 1 \) as mentioned above. Without loss of generality, we consider only \( \theta > \rho > 0 \) and \( \rho \theta > 1 \). As we will see soon, the \( \theta > \rho \geq 1 \) case can be handled by the results in [9], so our main concern is the case

\[
\theta \rho > 1 > \rho > 0.
\]

Let \((u, v)\) be a smooth solution to (1.1) with \( \theta > \rho^{-1} > 1 > \rho > 0 \). Our approach is based on the formal equivalence noticed in [1, 5], between the Lane–Emden system (1.1) and a fourth order problem, called the \( m \)-biharmonic equation. More precisely, let \( m := \frac{1}{\rho} + 1 > 2 \), as \( v = (-\Delta u)^{m-1} \), we derive that \( u \) satisfies \( \Delta^2_{\theta} u := \Delta(|\Delta u|^{m-2}\Delta u) = u^\theta \) in \( \mathbb{R}^N \). So we are led to consider \( \theta > m - 1 > 1 \) and

\[
\Delta^2_{\theta} u := \Delta(|\Delta u|^{m-2}\Delta u) = |u|^{\theta-1}u. \tag{1.7}
\]

Let \( \Omega \subset \mathbb{R}^N \), we say that \( u \in W^{2m}_{\text{loc}}(\Omega) \cap L^{\rho+1}_{\text{loc}}(\Omega) \) is a weak solutions of (1.7) in \( \Omega \), if for any regular bounded domain \( K \subset \Omega \), \( u \) is a critical point of the following functional

\[
I(v) = \frac{1}{m} \int_K |\Delta v|^{m}dx - \frac{1}{\theta + 1} \int_K |v|^{\theta+1}dx, \quad \forall \ v \in W^{2m}(K) \cap L^{\rho+1}(K).
\]

Naturally, a weak solution to (1.7) is said stable in \( \Omega \subset \mathbb{R}^N \), if

\[
\Delta u(h) := (m-1) \int_{\Omega} |\Delta u|^{m-2}|\Delta h|^2dx - \theta \int_{\Omega} |u|^{\theta-1}h^2dx \geq 0, \quad \forall \ h \in C_0^2(\Omega). \tag{1.8}
\]

A key point for our approach is to remark a relationship between the stability for the system (1.1) and the stability for the equation (1.7) (see lemma 2.1 below). This will permit us to handle the case \( 0 < \rho < 1 \) in (1.1) by using the structure of the \( m \)-biharmonic equation. In fact, we can prove the following Liouville type result.

**Theorem 1.2.** Let \( \theta > m - 1 > 1 \) and \( u \in W^{2m}_{\text{loc}}(\mathbb{R}^N) \cap L^{\rho+1}_{\text{loc}}(\mathbb{R}^N) \) be a weak solution of (1.7) which is stable outside a compact set. Assume that

\[
N < \frac{2m(\theta + 1)}{\theta - (m - 1)}, \tag{1.9}
\]

then \( u \equiv 0 \).

A direct calculation yields that if \( \rho \theta > 1 \) (or equivalently \( \theta > m - 1 \)),

\[
N < 2 + \alpha + \beta = \frac{2(p + 1)(\theta + 1)}{p\theta - 1} \quad \Leftrightarrow \quad (1.9) \quad \Leftrightarrow \quad \theta < \frac{N(m - 1) + 2m}{N - 2m}. \tag{1.9}
\]

It means that the range of pairs \( (p, \theta) \) satisfying (1.2) and \( \rho \theta > 1 \) corresponds exactly to the subcritical case of the \( m \)-biharmonic equation (1.7).

Another crucial step in our approach is to classify first the stable solutions of (1.1), see also proposition 2.1 below for the \( m \)-biharmonic equation.

**Proposition 1.1.** If \( p, \theta > 0 \) satisfies (1.2), then (1.1) has no smooth stable solution.

Establishing a Liouville type result for stable solution of (1.1) or (1.7) is delicate, even we can borrow some ideas from [4, 22]. We use as usual the stability to get some integral estimates, but the integrations by parts argument yields here many terms which are difficult to control, for example, the local \( L^m \) norm of \( \nabla u \), see lemma 2.3 below. Furthermore, the
classification of weak solutions stable at infinity to (1.7) is more involved than to handle (1.1), since the weak solutions to (1.7) are not $C^2$ functions. We will derive a variant of the Pohozaev identity with cut-off functions, which allows us to avoid the spherical integral terms in the standard Pohozaev identity.

The paper is organized as follows. In section 2, we give the proof of proposition 1.1. The proofs of theorems 1.1 and 1.2 are given respectively in sections 3 and 4. In the following, $C$ denotes always a generic positive constant, which could be changed from one line to another.

2. Classification of stable solutions

We prove here proposition 1.1. As mentioned before, we need only to consider the case $\theta > p$ and $p\theta > 1$. We split the proof into two cases: $\theta > p \geq 1$ and $\theta > p^{-1} > 1 > p > 0$.

2.1. The case $\theta > p \geq 1$

Let us recall a consequence of theorem 1.1 (with $\alpha = 0$ there) in [9].

**Theorem A.** Let $x_0$ be the largest root of the polynomial

$$H(x) = x^4 - p\theta x^3 \left[ 4x^2 - 2(\alpha + \beta)x + 1 \right].$$

(i) If $\frac{2}{\beta} < p \leq \theta$ then (1.1) has no stable classical solution if $N < 2 + 2x_0$.

(ii) If $1 \leq p \leq \min(\frac{2}{\beta}, \theta)$ and $p\theta > 1$, then (1.1) has no stable classical solution, if

$$N < 2 + 2x_0 \left[ \frac{p}{2} + \frac{(2-p)(p\theta - 1)}{(\theta + p - 2)(\theta + 1)} \right].$$

Performing the change of variables $x = \frac{s}{\beta} \sqrt{s}$ in (2.1), a direct computation shows that $H(x) = \left( \frac{s}{\beta} \right)^4 L(s)$ where

$$L(s) := s^4 - \frac{16p\theta(p + 1)}{\theta + 1} s^2 + \frac{16p\theta(p + 1)(p + \theta + 2)}{(\theta + 1)^2} s - \frac{16p\theta(p + 1)^2}{(\theta + 1)^2}.$$

Denote by $s_0$ the largest root of $L$, hence $x_0 = \frac{\beta}{\alpha} s_0$ and $H(x) < 0$ if and only if $L(s) < 0$. For $\theta > p \geq 1$, there holds

$$L(p + 1) = \left( p + 1 \right)^4 - \frac{16p\theta(p + 1)^3}{(\theta + 1)} + \frac{16p\theta(p + 1)^2(p + \theta + 2)}{(\theta + 1)^2} - \frac{16p\theta(p + 1)^2}{(\theta + 1)^2}$$

$$= \left( p + 1 \right)^4 - \frac{16p\theta(p + 1)^3}{(\theta + 1)} + \frac{16p\theta(p + 1)^2}{(\theta + 1)} + \frac{16p\theta(p + 1)^3}{(\theta + 1)^2} - \frac{16p\theta(p + 1)^2}{(\theta + 1)^2}$$

$$= \left( p + 1 \right)^2 \left[ \frac{1}{\theta + 1} - \frac{16p\theta}{(\theta + 1)^2} \right]$$

$$= \left( p + 1 \right)^2 \left[ \frac{1}{\theta + 1} - \frac{16p\theta}{(\theta + 1)^2} \right] < 0.$$

The last inequality holds true since

$$4p\theta - (p + 1)(\theta + 1) > 4p^2 - (p + 1)^2 \geq 0, \quad \forall \theta > p \geq 1.$$
As \( \lim_{s \to \infty} L(s) = \infty \), it follows that \( s_0 > p + 1 \). We get then
\[
2s_0 > (p + 1)\beta = 2 + \alpha + \beta, \quad \forall \theta > p \geq 1.
\]
If \( p > \frac{2}{\theta} \) by (i) of theorem A, the system (1.1) has no classical stable solution if \( N < 2 + \alpha + \beta \).

Suppose now \( 1 \leq p < \min\left(\frac{2}{\theta}, \theta \right) \). Observe that for all \( \theta > p \geq 1 \),
\[
\left[ p + \frac{2(2 - p)(p\theta - 1)}{(\theta + p - 2)(\theta + 1)} \right] \beta \geq \alpha + \beta \Leftrightarrow \left[ p + \frac{2(2 - p)(p\theta - 1)}{(\theta + p - 2)(\theta + 1)} \right] (\theta + 1) \geq p + \theta + 2
\]
\[
\Leftrightarrow p\theta - 1 + \frac{2(2 - p)(p\theta - 1)}{\theta + p - 2} \geq \theta + 1
\]
\[
\Leftrightarrow (p\theta - 1) \left[ 1 + \frac{2(2 - p)}{\theta + p - 2} \right] \geq \theta + 1
\]
\[
\Leftrightarrow (p\theta - 1)(\theta + 2 - p) \geq (\theta + p - 2)(\theta + 1)
\]
\[
\Leftrightarrow p\theta^2 - \theta(2 - p)p\theta \geq \theta^2 + (p - 1)\theta
\]
\[
\Leftrightarrow (p - 1)(\theta - p) \geq 0.
\]
As \( s_0 > p + 1 \geq 2 \), we have \( x_0 = \frac{\beta s_0}{2} \geq \beta \) and
\[
2 + \alpha + \beta \leq 2 + \beta \left[ p + \frac{2(2 - p)(p\theta - 1)}{(\theta + p - 2)(\theta + 1)} \right] \leq 2 + x_0 \left[ p + \frac{2(2 - p)(p\theta - 1)}{(\theta + p - 2)(\theta + 1)} \right].
\]
If \( N < 2 + \alpha + \beta \), using (ii) of theorem A, we are done.

To conclude, for all \( \theta > p \geq 1 \) and \( N < 2 + \alpha + \beta \), (1.1) has no smooth stable solution.

\[\square\]

2.2. The case \( \theta \rho > 1 \geq p > 0 \)

Here we handle the case \( 0 < p < 1 \). First of all, we need the following lemma which plays an important role in dealing with proposition 1.1.

**Lemma 2.1.** Let \((u, v)\) be a solution of system (1.1) with \( \theta > \frac{1}{p} := m - 1 > 1 \). Suppose that \((u, v)\) is stable in a regular bounded domain \( \Omega \), then \( u \) is a stable solution of equation (1.7).

**Proof.** By the definition of stability, there exist smooth positive functions \( \xi, \zeta \) and \( \eta \geq 0 \) such that
\[
-\Delta \xi = p\nu^{p-1} \xi + \eta \xi, \quad -\Delta \zeta = \theta u^{\theta - 1} \xi + \eta \zeta \quad \text{in} \quad \Omega.
\]

Using \((\xi, \zeta)\) as super-solution, \((\min_{\Omega} \xi, \min_{\Omega} \zeta)\) as sub-solution, and the standard monotone iterations, we can claim that there exist positive smooth functions \( \varphi, \chi \) verifying
\[
-\Delta \varphi = p\nu^{p-1} \chi, \quad -\Delta \chi = \theta u^{\theta - 1} \varphi \quad \text{in} \quad \Omega.
\]

Therefore, we have
\[
\theta u^{\theta - 1} \varphi = \Delta \left( \frac{1}{p} \nu^{1-p} \Delta \varphi \right) \quad \text{in} \quad \Omega.
\]

Let \( \gamma \in C^2_\infty(\Omega) \). Multiplying the above equation by \( \gamma^2 \varphi^{-1} \) and integrating by parts, there holds
\[
\int_\Omega \theta u^{\theta - 1} \gamma^2 \, dx = \frac{1}{p} \int_\Omega v^{1-p} \Delta \varphi \Delta (\gamma^2 \varphi^{-1}) \, dx \\
= \frac{1}{p} \int_\Omega v^{1-p} \Delta \varphi \left(-4 \gamma \nabla \varphi \cdot \nabla \gamma + 2 |\nabla \gamma|^2 \varphi + 2 \gamma \Delta \gamma + \frac{2 \gamma^2 |\nabla \varphi|^2 \varphi}{\gamma^2} - \frac{\gamma^2 \Delta \varphi}{\varphi^2}\right) \, dx.
\]

Using Cauchy–Schwarz’s inequality and the fact that \(-\Delta \varphi > 0\), we get
\[
\left| -4 \int_\Omega \frac{v^{1-p}}{p} \Delta \varphi \nabla \varphi \cdot \nabla \gamma \gamma \, dx \right| \leq -2 \int_\Omega \frac{v^{1-p}}{p} \Delta \varphi |\nabla \gamma|^2 \, dx - 2 \int_\Omega \frac{v^{1-p}}{p} \Delta \varphi |\nabla \varphi|^2 \, dx. \tag{2.2}
\]

Combining (2.2) and (2.3), one obtains, using again the Cauchy–Schwarz inequality,
\[
\int_\Omega \theta u^{\theta - 1} \gamma^2 \, dx \leq \frac{2}{p} \int_\Omega v^{1-p} \Delta \varphi \frac{\gamma \Delta \gamma}{\varphi} \, dx - \frac{1}{p} \int_\Omega v^{1-p} \frac{(\Delta \varphi)^2}{\varphi^2} \gamma^2 \, dx \\
\leq \frac{1}{p} \int_\Omega v^{1-p} \frac{(\Delta \varphi)^2}{\varphi^2} \gamma^2 \, dx + \frac{1}{p} \int_\Omega v^{1-p} (\Delta \gamma)^2 \, dx - \frac{1}{p} \int_\Omega v^{1-p} \frac{(\Delta \varphi)^2}{\varphi^2} \gamma^2 \, dx \\
= \frac{1}{p} \int_\Omega v^{1-p} (\Delta (\gamma^2))^2 \, dx.
\]

Recall that \(p = \frac{1}{m-1}\) and \((-\Delta u)^2 = v\), we obtain the desired result (1.8).

Therefore, to prove proposition 1.1 in the case \(p \in (0, 1)\) and \(p\theta > 1\), we need only to prove

**Proposition 2.1.** Let \(\theta > m - 1 > 1\), if \(u\) is a weak stable solution to the equation (1.7) in \(\mathbb{R}^N\) with \(N\) verifying (1.9), then \(u \equiv 0\).

To prove proposition 2.1, we use first the stability condition (1.8) to get the following crucial lemma which provides an important integral estimate for \(u\) and \(\Delta u\).

**Lemma 2.2.** Let \(u \in W^{2m,1}_{\text{loc}}(\Omega) \cap L^{p+1,1}_{\text{loc}}(\Omega)\) be a weak stable solution of (1.7) in \(\Omega\), with \(\theta > m - 1 > 1\). Then, for any integer
\[
k \geq \max \left( m, \frac{m(\theta + 1)}{2(\theta + 1 - m)} \right),
\]
there exists a positive constant \(C = C(N, \epsilon, m, k)\) such that for any \(\zeta \in C^2(\Omega)\) satisfying \(0 \leq \zeta \leq 1\),
\[
\int_\Omega |\Delta u|^m \zeta^k \, dx + \int_\Omega |u|^{\theta + 1} \zeta^k \, dx \leq C \left[ \int_\Omega (|\Delta \zeta|^m + |\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m)^{\frac{\theta + 1}{m(\theta + 1 - m)}} \, dx \right]. \tag{2.4}
\]

**Proof.** For any \(\epsilon \in (0, 1)\) and \(\eta \in C^2(\Omega)\), there holds
\[
\int_\Omega |\Delta u|^{m-2} (\Delta (\eta u))^2 \, dx = \int_\Omega |\Delta u|^m (\eta u + 2 \nabla u \nabla \eta + \eta \Delta u)^2 \, dx \\
\leq (1 + \epsilon) \int_\Omega |\Delta u|^m \eta^2 \, dx + \frac{C}{\epsilon} \int_\Omega |\Delta u|^{m-2} (u^2 |\Delta \eta|^2 + |\nabla u|^2 |\nabla \eta|^2) \, dx. \tag{2.5}
\]
Take $\eta = \zeta^{2k}$ with $\zeta \in \mathcal{C}_0^2(\Omega)$, $0 \leq \zeta \leq 1$ and $k \geq m > 2$. Apply Young’s inequality, we get
\[
\int_\Omega |u|^2 |\Delta u|^{m-2} |\Delta (\zeta^{2k})|^2 \, dx \leq C_k \int_\Omega |u|^2 |\Delta u|^{m-2} (|\Delta \zeta|^2 + |\nabla \zeta|^4) \zeta^{4k-4} \, dx
\]
and
\[
\int_\Omega |\Delta u|^{m-2} |\nabla u|^{2} |\nabla (\zeta^{2k})|^2 \, dx = 4k^2 \int_\Omega |\Delta u|^{m-2} |\nabla u|^{2} |\nabla \zeta|^2 \zeta^{4k-2} \, dx
\]
Inserting the two above estimates into (2.5), we arrive at
\[
\int_\Omega |\Delta u|^{m-2} (|u\zeta^{2k}|)^2 \, dx \leq (1 + C_k \epsilon \int_\Omega |\Delta u|^{m} \zeta^{4k} \, dx + \frac{C_{m,k}}{\epsilon^{m-2}} \int_\Omega |\nabla u|^{m} |\nabla \zeta|^{m} \zeta^{4k-m} \, dx
\]
\[
+ C_{e,m,k} \int_\Omega |u|^m (|\Delta \zeta|^2 + |\nabla \zeta|^4) \zeta^{4k-2m} \, dx. \tag{2.6}
\]
We need also the following technical lemma, which proof is given later.

**Lemma 2.3.** Let $k \geq m/2 > 1$ and $\epsilon > 0$, there exists $C_{N,e,m,k} > 0$ such that for any $u \in \mathcal{W}^m_{0,\text{loc}}(\Omega)$ verifying (1.8) and $\zeta \in \mathcal{C}_0^2(\Omega)$ with $0 \leq \zeta \leq 1$, there holds
\[
\int_\Omega |\nabla u|^m |\nabla \zeta|^{m} \zeta^{4k-m} \, dx \leq \epsilon \int_\Omega |\Delta u|^m \zeta^{4k} \, dx + C_{e,m,k} \int_\Omega |u|^m (|\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m) \zeta^{4k-2m} \, dx. \tag{2.7}
\]
Using lemma 2.3 with $\epsilon^n$ and (2.6), we see that
\[
\int_\Omega |\Delta u|^{m-2} (|u\zeta^{2k}|)^2 \, dx \leq C_{N,e,m,k} \int_\Omega |u|^m (|\Delta \zeta|^m + |\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m) \zeta^{4k-2m} \, dx
\]
\[
+ (1 + C_{m,k}) \epsilon \int_\Omega |\Delta u|^m \zeta^{4k} \, dx. \tag{2.8}
\]
Thanks to the approximation argument, the stability property (1.8) holds true with $u\zeta^{2k}$. We deduce then, for any $\epsilon > 0$, there exists $C_{N,e,m,k} > 0$ such that
\[
\theta \int_\Omega |u|^\theta + 1 \zeta^{4k} \, dx - (m - 1) \epsilon \int_\Omega |\Delta u|^m \zeta^{4k} \, dx
\]
\[
\leq C_{N,e,m,k} \int_\Omega |u|^m (|\Delta \zeta|^m + |\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m) \zeta^{4k-2m} \, dx. \tag{2.9}
\]
Moreover, multiplying the equation (1.7) by $u\zeta^{2k}$ and integrating by parts, there holds
\[
\int_\Omega |\Delta u|^m \zeta^{4k} \, dx - \int_\Omega |u|^\theta + 1 \zeta^{4k} \, dx \leq \int_\Omega |u||\Delta u|^{m-1} |\Delta (\zeta^{4k})| \, dx + C \int_\Omega |\Delta u|^{m-1} |\nabla u| |\nabla (\zeta^{4k})| \, dx.
\]
Using Young’s inequality and applying again lemma 2.3, we can deduce that for any $\epsilon > 0$, there exists $C_{N,\epsilon,m,k} > 0$ such that
\[
(1 - C_{m,k,\epsilon}) \int_{\Omega} |\Delta u|^m \zeta^{4k} \, dx - \int_{\Omega} |u|^{\theta+1} \zeta^{4k} \, dx \\
\leq C_{N,\epsilon,m,k} \int_{\Omega} |u|^m (|\Delta \zeta|^m + |\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m) \zeta^{4k-2m} \, dx.
\] (2.10)

Taking $\epsilon > 0$ but small enough, multiplying (2.10) by $\frac{(m-1)(1+2C_{m,k,\epsilon})}{1-C_{m,k,\epsilon}}$, adding it with (2.9), we get
\[
(m-1)C_{m,k,\epsilon} \int_{\Omega} |\Delta u|^m \zeta^{4k} \, dx + \left[ \theta - \frac{(m-1)(1+2C_{m,k,\epsilon})}{1-C_{m,k,\epsilon}} \right] \int_{\Omega} |u|^{\theta+1} \zeta^{4k} \, dx \\
\leq C_{N,\epsilon,m,k} \int_{\Omega} |u|^m (|\Delta \zeta|^m + |\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m) \zeta^{4k-2m} \, dx.
\]

As $\theta > m - 1 > 1$, using $\epsilon > 0$ small enough, we have
\[
\int_{\Omega} |\Delta u|^m \zeta^{4k} \, dx + \int_{\Omega} |u|^{\theta+1} \zeta^{4k} \, dx \leq C \int_{\Omega} |u|^m (|\Delta \zeta|^m + |\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m) \zeta^{4k-2m} \, dx.
\] (2.11)

For $k \geq \frac{m(\theta+1)}{4(m-\theta+1)}$ so that $4km \leq (4k-2m)(\theta+1)$, applying Hölder inequality, we conclude then
\[
\int_{\Omega} |\Delta u|^m \zeta^{4k} \, dx + \int_{\Omega} |u|^{\theta+1} \zeta^{4k} \, dx \\
\leq C \left[ \int_{\Omega} (|\Delta \zeta|^m + |\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m)^{1-\frac{(\theta+1)}{m}} \, dx \right]^{\frac{\theta+1}{m}} \left( \int_{\Omega} |u|^{\theta+1} \zeta^{4k-2m} \, dx \right)^{\frac{2}{m}} \\
\leq C \left[ \int_{\Omega} (|\Delta \zeta|^m + |\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m)^{\frac{(\theta+1)}{m}} \, dx \right] \left( \int_{\Omega} |u|^{\theta+1} \zeta^{4k} \, dx \right)^{\frac{2}{m}}.
\]

We get readily the estimate (2.4).

Now we choose $\phi_0$ a cut-off function in $C_c^\infty(B_2)$ verifying $0 \leq \phi_0 \leq 1$, and $\phi_0 \equiv 1$ in $B_1$. Applying (2.4) with $\zeta = \phi_0(R^{-1} \cdot)$ for $R > 0$, there holds
\[
\int_{B_R} |u|^{\theta+1} \, dx \leq C \int_{\mathbb{R}^N} |u|^{\theta+1} \zeta^{4k} \, dx \leq CR^{\frac{m(\theta+1)}{2(m-\theta+1)} - 2m}.
\]

Under the assumption (1.9), tending $R \to \infty$, we obtain $u \equiv 0$, we prove then proposition 2.1, hence the case $\theta p > 1 > p > 0$ for proposition 1.1.

**Proof of lemma 2.3.** A direct calculation gives
\[
\int_{\Omega} |\nabla u|^m |\nabla \zeta|^m \zeta^{4k-m} \, dx = \int_{\Omega} \nabla u \cdot \nabla u |\nabla u|^{m-2} |\nabla \zeta|^m \zeta^{4k-m} \, dx \\
= - \int_{\Omega} \text{div} (\nabla u |\nabla u|^{m-2}) u |\nabla \zeta|^m \zeta^{4k-m} \, dx \\
- \int_{\Omega} u |\nabla u|^{m-2} \nabla u \cdot \nabla (|\nabla \zeta|^m \zeta^{4k-m}) \, dx
\] (2.12)

\[= I_1 + I_2.\]
The integral $I_1$ can be estimated as

\[
I_1 = -(m - 2) \int_{\Omega} u|\nabla u|^m|\nabla \zeta|^{2m} u(\nabla u, \nabla u)\zeta^{4k-2m} \, dx - \int_{\Omega} u|\Delta u||\nabla u|^m|\nabla \zeta|^{4k-m} \, dx \\
\leq C_m \int_{\Omega} |u||\nabla u||\nabla \zeta|^{m} \zeta^{4k-m} \, dx + \int_{\Omega} |u||\Delta u||\nabla u|^m|\nabla \zeta|^{m} \zeta^{4k-m} \, dx.
\]

Applying Young’s inequality, there holds, for any $\epsilon > 0$,

\[
\int_{\Omega} |u||\Delta u||\nabla u|^m|\nabla \zeta|^{m} \zeta^{4k-m} \, dx \\
\leq C_{\epsilon,m} \int_{\Omega} |u|^2 |\Delta u|^2 |\nabla \zeta|^{2m} \zeta^{4k-m} \, dx + \epsilon \int_{\Omega} |\nabla u|^m |\nabla \zeta|^{4k-m} \, dx \\
\leq C_{\epsilon,m} \int_{\Omega} |u|^2 |\nabla \zeta|^{2m} \zeta^{4k-2m} \, dx + \epsilon \int_{\Omega} |\nabla u|^m |\nabla \zeta|^{4k-m} \, dx + \epsilon \int_{\Omega} |\nabla u|^m |\nabla \zeta|^{4k-m} \, dx. \tag{2.13}
\]

On the other hand,

\[
\int_{\Omega} |\nabla^2 u|^m |\nabla \zeta|^{4k-m} \, dx \\
\leq C_{\epsilon,m} \int_{\Omega} |\nabla^2 u|^2 |\nabla \zeta|^{4k-m} \, dx + \epsilon \int_{\Omega} |\nabla u|^m |\nabla \zeta|^{4k-m} \, dx \\
\leq C_{\epsilon,m} \int_{\Omega} |\nabla u|^m |\nabla \zeta|^{2m} \zeta^{4k-2m} \, dx + \epsilon \int_{\Omega} |\nabla^2 u|^m |\nabla \zeta|^{4k-m} \, dx. \tag{2.14}
\]

Now we shall estimate the integral

\[
\int_{\Omega} |\nabla^2 u|^m \zeta^{4k} \, dx.
\]

Remark that there exists $C_0(N, m) > 0$ such that

\[
\int_{\mathbb{R}^n} |\nabla^2 \varphi|^m \, dx \leq C_0(N, m) \int_{\mathbb{R}^n} |\Delta \varphi|^m \, dx, \quad \forall \varphi \in W^{2,m}(\mathbb{R}^N). \tag{2.15}
\]

We can prove it firstly for $\varphi \in W^{2,m}_0(B_1)$ with elliptic theory, then for general $\varphi \in W^{2,m}(\mathbb{R}^N)$ with approximation and scaling argument. As $u_\zeta \in W^{2,m}_0(\Omega) \subset W^{2,m}(\mathbb{R}^N)$, (2.15) implies that

\[
\int_{\Omega} |\nabla^2 (u_\zeta^{\frac{m}{k}})|^m \, dx \leq C_0(N, m) \int_{\Omega} |\Delta (u_\zeta^{\frac{m}{k}})|^m \, dx \\
\leq C_{N,m} \int_{\Omega} |\Delta u|^m |\nabla \zeta|^{4k-m} \, dx + C_{N,m,k} \int_{\Omega} |\nabla u|^m |\nabla \zeta|^{4k-m} \, dx \\
+ C_{N,m,k} \int_{\Omega} |u|^m (|\nabla \zeta|^{2m} + |\nabla^2 \zeta|^m) \zeta^{4k-2m} \, dx.
\]

Let $k > m$, we get then
\[
\int_{\Omega} \left| \nabla^2 u \right|^m \zeta^{4k} \, dx \leq C \int_{\Omega} \left| \nabla^2 (u \zeta^{\frac{m}{2}}) \right|^m \, dx + C_{m,k} \int_{\Omega} \left| \nabla u \right|^m \left| \nabla \zeta \right|^m \zeta^{4k-m} \, dx \\
+ C_{m,k} \int_{\Omega} \left| u \right|^m \left( \left| \nabla \zeta \right|^{2m} + \left| \nabla^2 \zeta \right|^m \right) \zeta^{4k-2m} \, dx \\
\leq C_{N,m} \int_{\Omega} \left| \Delta u \right|^m \zeta^{4k} \, dx + C_{N,m,k} \int_{\Omega} \left| \nabla u \right|^m \left| \nabla \zeta \right|^m \zeta^{4k-m} \, dx \\
+ C_{N,m,k} \int_{\Omega} \left| u \right|^m \left( \left| \nabla \zeta \right|^{2m} + \left| \nabla^2 \zeta \right|^m \right) \zeta^{4k-2m} \, dx. \tag{2.16}
\]

Combining (2.13), (2.14) and (2.16), we arrive at
\[
I_1 \leq C_{N,m,k} \epsilon \int_{\Omega} |\Delta u|^m \zeta^{4k} \, dx + C_m \epsilon \int_{\Omega} \left| \nabla u \right|^m \left| \nabla \zeta \right|^m \zeta^{4k-m} \, dx \\
+ C_{N,e,m,k} \int_{\Omega} \left| u \right|^m \left( \left| \nabla \zeta \right|^{2m} + \left| \nabla^2 \zeta \right|^m \right) \zeta^{4k-2m} \, dx. \tag{2.17}
\]

Furthermore, by Young’s inequality,
\[
I_2 = -m \int_{\Omega} u |\nabla u|^{m-2} \left| \nabla \zeta \right|^{m-2} \nabla^2 \zeta (\nabla \zeta, \nabla u) \zeta^{4k-m} \, dx \\
- (4k - m) \int_{\Omega} u |\nabla u|^{m-2} \left| \nabla \zeta \right|^m (\nabla u \cdot \nabla \zeta) \zeta^{4k-m-1} \, dx \\
\leq C_{m,k} \int_{\Omega} \left| u \right| \left| \nabla u \right|^{m-1} \left| \nabla \zeta \right|^{m-1} \left( \left| \nabla \zeta \right|^2 + \left| \nabla^2 \zeta \right|^m \right) \zeta^{4k-m-1} \, dx \\
\leq C_{e,m,k} \int_{\Omega} \left| u \right|^m \left( \left| \nabla \zeta \right|^{2m} + \left| \nabla^2 \zeta \right|^m \right) \zeta^{4k-2m} \, dx + \epsilon \int_{\Omega} \left| \nabla u \right|^m \left| \nabla \zeta \right|^m \zeta^{4k-m} \, dx. \tag{2.18}
\]

Combining (2.17), (2.18) with (2.12), one concludes
\[
(1 - C_{N,m,k}) \epsilon \int_{\Omega} \left| \nabla u \right|^m \zeta^{4k-m} \, dx \leq C_{N,e,m,k} \int_{\Omega} \left| u \right|^m \left( \left| \nabla \zeta \right|^{2m} + \left| \nabla^2 \zeta \right|^m \right) \zeta^{4k-2m} \, dx \\
+ C_{N,m,k} \epsilon \int_{\Omega} \left| \Delta u \right|^m \zeta^{4k} \, dx.
\]

This means that (2.7) holds true for \( \epsilon > 0 \) small enough, hence for any \( \epsilon > 0 \).

\section{3. Proof of theorem 1.1}

In this section, we prove theorem 1.1. As already mentioned, we need only to handle the case \( p^\theta > 1 \). We use first the classification for stable solutions, proposition 1.1 to obtain the decay estimates for stable at infinity solutions of (1.1).

\textbf{Lemma 3.1.} Let \( p, \theta > 0 \) verify \( p^\theta > 1 \) and (1.4). Let \( (u, v) \) be a smooth solution of (1.1) which is stable outside a compact set. Then there exists a constant \( C \) such that
\[
\sum_{k \leq 2} \left[ |x|^{\alpha+k} |\nabla^k u(x)| + |x|^{\beta+k} |\nabla^k v(x)| \right] \leq C, \quad \forall \ x \in \mathbb{R}^N. \tag{3.1}
\]
Proof. Assume that \((u, v)\) is stable outside \(B_{R_0}\). Denote

\[
W(x) = \sum_{k \leq 2} \left[ |\nabla^k u(x)|^\frac{\theta}{\theta + 1} + |\nabla^k v(x)|^\frac{\theta}{\theta + 1} \right].
\]

Suppose that (3.1) does not hold true. Let \(d(x) = |x| - R_0\), there holds

\[
\sup_{\mathbb{R}^N \setminus B_{R_0}} W(x) d(x) = \infty,
\]

or equally there exists a sequence \((x_n)\) such that \(|x_n| > R_0\) and \(W(x_n) d(x_n) > n\) for \(n \geq 1\). Since \((u, v)\) are smooth in \(\mathbb{R}^N\), then \(d(x_n) \to \infty\). By doubling the lemma [14], there exists another sequence \((y_n)\) such that for any \(n \geq 1, |y_n| > R_0\),

1. \(W(y_n) d(y_n) \geq n\);
2. \(W(y_n) \geq W(x_n)\);
3. \(W(z) \leq 2W(y_n)\) for \(|z| > R_0\) such that \(|z - y_n| \leq \frac{n}{W(y_n)}\).

Let \((u, v)\) be a solution of (1.1), consider the sequence of functions

\[
\tilde{u}_n(x) = \lambda_n^\alpha u(y_n + \lambda_n x), \quad \tilde{v}_n(x) = \lambda_n^\beta v(y_n + \lambda_n x), \quad \text{with} \quad \lambda_n = W(y_n)^{-1}.
\]

It is well known that \((\tilde{u}_n, \tilde{v}_n)\) are a sequence of solutions to (1.1). Moreover,

\[
W_n(x) := \sum_{k \leq 2} \left( |\nabla^k \tilde{u}_n(x)|^\frac{\theta}{\theta + 1} + |\nabla^k \tilde{v}_n(x)|^\frac{\theta}{\theta + 1} \right) = \lambda_n W(y_n + \lambda_n x), \quad \forall x \in \mathbb{R}^N.
\]

By (i), we have \(B_{\lambda_n}(y_n) \subset \mathbb{R}^N \setminus B_{R_0}\), and we can readily check that \((\tilde{u}_n, \tilde{v}_n)\) is stable in \(B_n\) since \((u, v)\) is stable in \(\mathbb{R}^N \setminus B_{R_0}\). Using (iii), there holds, for all \(n \geq 1\),

\[
W_n(x) \leq 2 W_n(0) = 2 \quad \text{in} \quad B_n.
\]

(3.2)

From (3.2) and standard elliptic theory, up to a subsequence, \((\tilde{u}_n, \tilde{v}_n)\) converges to \((u_\infty, v_\infty)\) in \(C_0^\infty(\mathbb{R}^N)\). Therefore

\[
\sum_{k \leq 2} \left( |\nabla^k u_\infty(0)|^\frac{\theta}{\theta + 1} + |\nabla^k v_\infty(0)|^\frac{\theta}{\theta + 1} \right) = 1.
\]

So \((u_\infty, v_\infty)\) is nontrivial. Clearly, \((u_\infty, v_\infty)\) a smooth positive solution to (1.1). Using again the elliptic theory, it is not difficult to see that \((u_\infty, v_\infty)\) is stable in \(\mathbb{R}^N\). However, this contradicts proposition 1.1 because \(p, \theta\) satisfy (1.2). Hence the hypothesis was wrong, i.e. the estimate (3.1) holds true. \(\Box\)

Another tool is the following classical Pohozaev identity (see [12, 15, 21]).

Lemma 3.2. Let \((u, v)\) be a solution to (1.1). Therefore for any regular bounded domain \(\Omega\),

\[
\frac{2(p + 1) - p \theta N}{p + 1} \int_{\Omega} u^{p+1} dx + \frac{N}{\theta + 1} \int_{\Omega} u^{\theta+1} dx
\]

\[
= \int_{\partial \Omega} \left[ \frac{\theta + 1}{\theta + 2} |\nabla u(x)|^2 + \frac{p - 1}{p} \int_{\Omega} u^{p+1} dx \right] \left[ \frac{\partial u}{\partial \nu} - \frac{\partial (\nabla u \cdot x)}{\partial \nu} \right] dx - \int_{\partial \Omega} \frac{\partial (\nabla u \cdot x)}{\partial \nu} d\sigma.
\]

(3.3)
We claim then

**Lemma 3.3.** Let \( p, \theta > 0 \) satisfy \( p \theta > 1 \) and (1.4). Let \((u, v)\) be a smooth solution of (1.1) which is stable outside a compact set, then \( v \in L^{p + 1}(\mathbb{R}^N) \), \( u \in L^{\theta + 1}(\mathbb{R}^N) \) and

\[
\frac{2(p + 1) - pN}{p + 1} \int_{\mathbb{R}^N} v^{p + 1} \, dx + \frac{N}{\theta + 1} \int_{\mathbb{R}^N} u^{\theta + 1} \, dx = 0. \tag{3.4}
\]

**Proof.** Applying (3.1), we have (noticing that \( \alpha(\theta + 1) = (p + 1)\beta = 2 + \alpha + \beta \))

\[
u^{\theta + 1}(x) + v^{p + 1}(x) \leq C(1 + |x|)^{-(2 + \alpha + \beta)} \text{ in } \mathbb{R}^N.
\]

By (1.4), then \( v \in L^{p + 1}(\mathbb{R}^N) \) and \( u \in L^{\theta + 1}(\mathbb{R}^N) \). Using lemma 3.2 with \( \Omega = B_R \), there holds

\[
\frac{2(p + 1) - pN}{p + 1} \int_{B_R} v^{p + 1} \, dx + \frac{N}{\theta + 1} \int_{B_R} |u|^{\theta + 1} \, dx
\]

\[
= \int_{\partial B_R} \left[ R \frac{\partial u}{\partial r} - \frac{1}{p + 1} v^{p + 1} - v \frac{\partial (\nabla u \cdot x)}{\partial r} + \frac{R}{\theta + 1} |u|^{\theta + 1} \right] \, d\sigma. \tag{3.5}
\]

Applying again (3.1) and \( N < 2 + \alpha + \beta \), we deduce that

\[
\int_{\partial B_R} \left[ R \frac{\partial u}{\partial r} - \frac{1}{p + 1} v^{p + 1} - v \frac{\partial (\nabla u \cdot x)}{\partial r} + \frac{R}{\theta + 1} |u|^{\theta + 1} \right] \, d\sigma \to 0, \quad \text{as } R \to \infty.
\]

Taking the limit \( R \to \infty \) in (3.5), the claim follows. \( \square \)

**Proof of theorem 1.1 completed.** We are now in position to conclude. Suppose that \((u, v)\) is a classical solution to (1.1) stable at infinity, with \( p \theta > 1 \) verifying (1.4). Choose \( \phi_0 \) a cut-off function in \( C_\infty^\infty(B_1) \) verifying \( 0 \leq \phi_0 \leq 1 \), and \( \phi_0 \equiv 1 \) in \( B_1 \). Denote \( \zeta = \phi_0(R^{-1}x) \) and \( A_R = B_{2R} \setminus B_R \). By the system (1.1), there holds

\[
\int_{B_{2R}} v^{p + 1} \, dx - \int_{B_{2R}} u^{\theta + 1} \, dx = \int_{B_{2R}} u \zeta \Delta v \, dx - \int_{B_{2R}} u \zeta \Delta u \, dx
\]

\[
= \int_{B_{2R}} v \left( 2 \nabla u \cdot \nabla \zeta + u \Delta \zeta \right) \, dx
\]

\[
\leq \frac{C}{R^2} \int_{A_R} u v \, dx + \frac{C}{R} \int_{A_R} v |\nabla u| \, dx.
\]

Using (3.1), and tending \( R \to \infty \), as \( N < 2 + \alpha + \beta \), we have

\[
\int_{\mathbb{R}^N} v^{p + 1} \, dx = \int_{\mathbb{R}^N} u^{\theta + 1} \, dx.
\]

Substituting this in (3.4),

\[
\left( \frac{2(p + 1) - pN}{p + 1} + \frac{N}{\theta + 1} \right) \int_{\mathbb{R}^N} u^{\theta + 1} \, dx = 0.
\]

922
However, (1.4) implies that
\[ \frac{2(p + 1) - pN}{p + 1} + \frac{N}{\theta + 1} = 2 - \frac{(p\theta - 1)N}{(p + 1)(\theta + 1)} = 2 - \frac{2N}{2 + \alpha + \beta} > 0. \]

\( u \equiv 0 \) in \( \mathbb{R}^N \) which is absurd, so we are done. \( \square \)

4. Proof of theorem 1.2

The approach is similar to that for theorem 1.1. We derive first some integral estimates thanks to lemma 2.2. Suppose that \( u \) is stable outside the ball \( B_{R_0} \). Let \( R > R_0 + 3 \) and \( \zeta \in C^2_c(\mathbb{R}^N \setminus B_{R_0}) \) verifying that \( 0 \leq \zeta \leq 1 \) and
\[
\zeta(x) = \begin{cases} 
0 & \text{for } |x| \leq R_0 + 1, \ |x| \geq 2R, \\
1 & \text{for } R_0 + 2 \leq |x| \leq R.
\end{cases}
\]

Clearly, we can assume that there exists \( C > 0 \) independent on \( R \) such that
\[
\| \zeta \|_{C^2(B_{R_0+1})} \leq C \quad \text{and} \quad R|\nabla \zeta(x)| + R^2|\nabla^2 \zeta(x)| \leq C \quad \text{in } A_R = B_{2R} \setminus B_R.
\]

Applying the estimate (2.4) with \( \zeta \), we get readily
\[
\int_{R_0+2 \leq |x| \leq R} |\Delta u|^m dx + \int_{R_0+2 \leq |x| \leq R} |u|^\theta+1 dx \leq C \left( 1 + R^{\frac{2m(\theta+1)}{\theta+1}} \right). \tag{4.1}
\]

Using (1.9) and tending \( R \to \infty \), we obtain
\[
u \in L^{\theta+1}(\mathbb{R}^N) \quad \text{and} \quad \Delta u \in L^m(\mathbb{R}^N).
\tag{4.2}
\]

By Hölder’s inequality, there holds
\[
R^{-2m} \int_{B_R} |u|^m dx \leq CR^{-\frac{\theta+1+\theta}{\theta+1}} - 2m \left( \int_{B_R} |u|^\theta+1 dx \right)^{\frac{\theta+1}{\theta+1}}.
\]

On the other hand, by standard scaling argument, there exists \( C > 0 \) such that for any \( R > 0 \), any \( u \in W^{2,m}(A_R) \) with \( A_R = B_{2R} \setminus B_R \),
\[
R^{-m} \int_{A_R} |\nabla u|^m dx \leq C \int_{A_R} |\Delta u|^m dx + CR^{-2m} \int_{A_R} |u|^m dx.
\]

Therefore, under the assumptions of theorem 1.2, we deduce that
\[
R^{-2m} \int_{A_R} |u|^m dx + R^{-m} \int_{A_R} |\nabla u|^m dx \to 0 \quad \text{as } R \to \infty. \tag{4.3}
\]

Let \( \zeta(x) = \phi_0(R^{-1}x) \) with a standard cut-off function \( \phi_0 \in C^2_c(B_1) \), \( \phi_0 \equiv 1 \) in \( B_1 \). Applying the estimate (2.16) and using (4.2) and (4.3), there holds
\[
\int_{\mathbb{R}^N} |\nabla^2 u|^m dx < \infty. \tag{4.4}
\]

However, as already mentioned, the weak solutions of (1.7) are in general not belongs to \( C^2 \), so we cannot use the standard Pohozaev identity similar to (3.3) because of the boundary
Let $u$ be a weak solution to (1.7) with $m > 2$. Then for any $\psi \in C^2_0(\Omega)$,
\[
\frac{N}{\theta + 1} \int_{\Omega} |u|^\theta \psi \, dx - \frac{N - 2m}{m} \int_{\Omega} |\Delta u|^m \psi \, dx
\]
\[
= - \frac{1}{\theta + 1} \int_{\Omega} |u|^{\theta + 1} (\nabla \psi \cdot x) \, dx + \frac{1}{m} \int_{\Omega} (\nabla \psi \cdot x) |\Delta u|^m \, dx
\]
\[
- \int_{\Omega} |\Delta u|^{m-2} \left[ 2\Delta u (\nabla u \cdot \nabla \psi) + 2\Delta u \nabla^2 u (x, \nabla \psi) + \Delta u (\nabla u \cdot x) \Delta \psi \right] \, dx.
\] (4.5)

This implies that if $u$ is a weak solution of (1.7), stable at infinity with $1 < m - 1 < \theta$ and $N$ verifying (1.9), then
\[
\frac{N - 2m}{m} \int_{\mathbb{R}^N} |\Delta u|^m \, dx = \frac{N}{\theta + 1} \int_{\mathbb{R}^N} |u|^\theta \, dx.
\] (4.6)

Indeed, let $\psi$ in (4.5) be defined by $\psi(x) = \phi_0(R^{-1}x)$ with a standard cut-off function $\phi_0 \in C^2_0(B_2)$, $\phi_0 \equiv 1$ in $B_1$. Denote the right hand side in (4.5) by $I_R$. Remark that $\nabla \psi \neq 0$ only in $A_R = B_{2R} \setminus B_R$ and $\|\nabla^k \psi\|_{\infty} \leq C_i R^{-k}$, there holds

\[
|I_R| \leq C \int_{A_R} \left( |u|^{\theta + 1} + |\Delta u|^m \right) \, dx + \frac{C}{R} \int_{A_R} |\Delta u|^{m-1} |\nabla u| \, dx + C \int_{A_R} |\Delta u|^{m-1} |\nabla^2 u| \, dx.
\]

Thanks to the estimates (4.2)–(4.4) and Hölder’s inequality, clearly $\lim_{R \to \infty} I_R = 0$, hence we get (4.6).

On the other hand, using $u\psi$ as test function in (1.7), we have
\[
\int_{B_{2R}} |\Delta u|^m \psi \, dx - \int_{B_{2R}} |u|^{\theta + 1} \psi \, dx \leq C \int_{B_{2R}} |u||\Delta u|^{m-1} |\nabla \psi| \, dx + C \int_{B_{2R}} |\Delta u|^{m-1} |\nabla u||\nabla \psi| \, dx
\]
\[
\leq C \int_{A_R} |u||\Delta u|^{m-1} \, dx + \frac{C}{R} \int_{A_R} |\Delta u|^{m-1} |\nabla u| \, dx.
\]

Apply Hölder’s inequality, (4.2), (4.3) and tending $R$ to $\infty$, we so obtain
\[
\int_{\mathbb{R}^N} |u|^{\theta + 1} \, dx = \int_{\mathbb{R}^N} |\Delta u|^m \, dx.
\] (4.7)

Combining (4.6) and (4.7), there holds
\[
\left( \frac{N - 2m}{m} - \frac{N}{\theta + 1} \right) \int_{\mathbb{R}^N} |u|^{\theta + 1} \, dx = 0.
\]

We are done, since (1.9) implies that $\frac{N - 2m}{m} - \frac{N}{\theta + 1} < 0$. \qed

Appendix

We prove here the lemma 4.1. Let $\psi \in C^2_\infty(\Omega)$, multiplying equation (1.7) by $\nabla u \cdot x \psi$ and integrating by parts, we get

$$\int_\Omega |u|^{\theta-1} u (\nabla u \cdot x) \psi \, dx = \int_\Omega |\Delta u|^{m-2} \Delta u (\nabla u \cdot x \psi) \, dx$$

$$= \int_\Omega |\Delta u|^{m-2} \Delta u \left[ (\nabla (\Delta u) \cdot x) \psi + 2 \Delta u \psi + 2 \nabla (\nabla u \cdot x) \cdot \nabla \psi + (\nabla u \cdot x) \Delta \psi \right] \, dx.$$ 

Direct calculation yields $\nabla (\nabla u \cdot x) \cdot \nabla \psi = \nabla^2 u(x, \nabla \psi) + (\nabla u \cdot \nabla \psi)$ and

$$\int_\Omega |\Delta u|^{m-2} \Delta u \left[ (\nabla (\Delta u) \cdot x) \psi + 2 \Delta u \psi \right] \, dx = \int_\Omega \frac{\nabla |\Delta u|^m}{m} \cdot x \psi \, dx + 2 \int_\Omega |\Delta u|^m \psi \, dx$$

$$= \frac{2m - N}{m} \int_\Omega |\Delta u|^m \psi \, dx - \frac{1}{m} \int_\Omega |\Delta u|^m (\nabla \psi \cdot x) \, dx.$$ 

Moreover,

$$\int_\Omega |u|^{\theta-1} u (\nabla u \cdot x) \psi \, dx = -\frac{1}{\theta + 1} \int_\Omega |u|^\theta \psi \, dx$$

$$- \frac{N}{\theta + 1} \int_\Omega |u|^\theta \psi \, dx - \frac{1}{\theta + 1} \int_\Omega |u|^\theta x \cdot \nabla \psi \, dx.$$ 

Therefore, the claim follows by regrouping the above equalities. □
