We present our preliminary results for the computation of the non-perturbative running of renormalized quark masses in $N_f = 3$ QCD, between the electroweak and hadronic scales, using standard finite-size scaling techniques. The computation is carried out to very high precision, using massless $\mathcal{O}(a)$ improved Wilson quarks. Following the strategy adopted by the ALPHA Collaboration for the running coupling, different schemes are used above and below a scale $\mu_0 \sim m_b$, which differ by using either the Schrödinger Functional or Gradient Flow renormalized coupling. We discuss our results for the running in both regions, and the procedure to match the two schemes.
Non-perturbative running of quark masses in three-flavour QCD

D. Preti

Figure 1: The plots show the SSFs in both SF and GF coupling regions with respectively blue and red points (the two most hadronic points have not been used in the current analysis). The error bands coming from fitting $\sigma_P$ and $\tau$ are laying on top of each others showing a remarkable agreement between the two fitting procedures. The comparison with the LO and NLO is also provided (the latter is known only in the SF coupling region).

1. Introduction

The high precision computation of quark masses requires to control the Renormalization Group (RG) running very accurately and in a large range of scales. The equations describing the RG flow in a mass-independent scheme for the renormalized coupling $\bar{g}(\mu)$ and the renormalized mass $\bar{m}(\mu)$ respectively read

$$\mu \frac{\partial}{\partial \mu} \bar{g}(\mu) = \beta(\bar{g}(\mu)),$$

$$\mu \frac{\partial}{\partial \mu} \bar{m}(\mu) = \tau(\bar{g}(\mu))\bar{m}(\mu).$$

They admit perturbative expansion

$$\beta(g) \overset{g \to 0}{\sim} -g^3(b_0 + b_1 g^2 + b_2 g^4 + \mathcal{O}(g^6)),
$$

$$\tau(g) \overset{g \to 0}{\sim} -g^2(d_0 + d_1 g^2 + d_2 g^4 + \mathcal{O}(g^6)),$$

with universal coefficients $b_0, b_1, d_0$, while all the others are scheme-dependent. We can also define through formal solution of (1.1), (1.2) the renormalization group invariants (RGI) for both coupling and mass (the latter is valid for any multiplicatively renormalizable composite operator [1]) respectively as

$$\Lambda = \mu \left[b_0 \bar{g}^2(\mu)\right]^{-b_1/(2b_0^2)} e^{-1/(2b_0 \bar{g}^2(\mu))} \exp\left\{- \int_0^{\bar{g}(\mu)} dg \left[\frac{1}{\beta(g)} + \frac{1}{b_0 g^3} - \frac{b_1}{b_0^2 g}\right]\right\},
$$

$$M = \bar{m}(\mu) \left[2b_0 \bar{g}^2(\mu)\right]^{-d_0/(2b_0)} \exp\left\{- \int_0^{\bar{g}(\mu)} dg \left[\frac{\tau(g)}{\beta(g)} - \frac{d_0}{b_0 g}\right]\right\}.
$$

In order to compute the running over several orders of magnitude we use a recursive procedure in finite volume with Schrödinger Functional (SF) [2] boundary conditions and massless, non-perturbatively $\mathcal{O}(a)$-improved Wilson fermions. Following the standard SF approach we identify
Non-perturbative running of quark masses in three-flavour QCD

2. Step Scaling Functions and SF Renormalization Conditions

In our computation the renormalization group functions are accessed through the Step Scaling Functions (SSFs) \( \sigma \) and \( \sigma_P \) defining the scale evolution of a factor \( s \geq 1 \) for the coupling and the quark mass respectively as

\[
-\ln(s) = \int \frac{\sqrt{g^2(\mu/s)}}{\bar{g}(\mu)} \; dg, \quad \text{with} \quad \sigma(s, \bar{g}^2(\mu)) = \frac{\bar{g}^2(\mu/s)}{\bar{g}^2(\mu)},
\]

\[
\sigma_P(s, \bar{g}^2(\mu)) = \frac{\bar{m}(\mu)}{\bar{m}(\mu/s)} = \exp \left\{ -\int \frac{\sqrt{g^2(\mu/s)}}{\sqrt{\bar{g}^2(\mu)}} \frac{\tau(g)}{\bar{g}(g)} \; dg \right\}.
\]

In order to compute (2.2) on the lattice, we identify the renormalization pattern for the quark masses through the (non-singlet) axial Ward identity \( (i \neq j) \)

\[
\partial_\mu (A_R)_{ij}^{\mu} = (\bar{m}_i + \bar{m}_j) P_R^{ij}.
\]

The renormalized currents are given by

\[
(A_R)_{ij}^{\mu}(x) = Z_A \bar{\psi}_i(x) \gamma_\mu \gamma_5 \psi_j(x), \quad (P_R)_{ij}^{\mu}(x) = Z_P \bar{\psi}_i(x) \gamma_\mu \psi_j(x),
\]

where \( i, j \) are flavour indices. With \( Z_A \) being finite, all the scale dependence of the mass is given by the inverse of the pseudoscalar renormalization constant \( Z_P \approx 1/Z_m \). The renormalization constant
An exception is given by continuum extrapolation for the SSF in both regions we computed the steps from which the continuum limit in the SF \[ \text{Non-perturbative running of quark masses in three-flavour QCD} \]

\[ \text{computation of the SSF for } u_{SF} = [1.1100, 1.1844, 1.2565, 1.3627, 1.4808, 1.6173, 1.7943, 2.0120] \]

\[ \text{and } u_{GF} = [2.1257, 2.3900, 2.7359, 3.2029, 3.8643, 4.4901, 5.3010]. \]

\[ \text{In order to compute the continuum extrapolation for the SSF in both regions we computed the steps } L/a \rightarrow 2L/a = [6 \rightarrow 12, 8 \rightarrow 16, 12 \rightarrow 24] \]

\[ \text{for the SF couplings and } [8 \rightarrow 16, 12 \rightarrow 24, 16 \rightarrow 32] \]

\[ \text{for the GF couplings}^{1}. \]

\[ \text{An exception is given by } u_{SF} = 2.012 \text{ where we added the extra step } 16 \rightarrow 32 \text{ (as in Fig. 2) in order to have a better control of the continuum limit since this point plays an important rôle in the} \]

\[ \text{non-perturbative scheme matching procedure.} \]
Both approaches discussed above completely agree within errors.

$\bar{p}_0 = -d_0 \log(2)$, or as an alternative approach perform a fit directly for the numerator $\tau(g)$ in (2.2), viz.

$$\sigma_p(s, \bar{g}^2(\mu)) = 1 + \bar{p}_0 u + p_1 u^2 + p_2 u^3 + \mathcal{O}(u^4) = \exp \left\{ - \int \frac{\beta^\text{NP}(g')}{\bar{g}^2(\mu)} dg' \right\}. \quad (3.1)$$

The anomalous dimension, as depicted in Figure 3, is fitted as a polynomial

$$\tau^\text{NP}(g) = \begin{cases} -g^2(d_0 + \bar{d}_1 g^2 + d_2 g^4 + d_3 g^6 + \mathcal{O}(u^8)) & \text{when } g \in \text{SF region} \\ -\bar{g}^2(d_0 + \bar{d}_1 g^2 + d_2 g^4 + d_3 g^6 + \mathcal{O}(u^8)) & \text{when } g \in \text{GF region} \end{cases}, \quad (3.2)$$

with coefficients $\bar{d}_i$ fixed to their PT values. The fitted expression of $\beta^\text{NP}$ in both SF and GF regions [12, 11] is a fundamental input that let us to isolate the anomalous dimension from the ratio in Eq. (2.2). As displayed in Fig. 1 both approaches discussed above completely agrees within errors.

The running from an hadronic scale given by $L_{\text{had}} \sim 200$ MeV can be written as

$$\frac{M}{\bar{m}(L_{\text{had}})} = \frac{\bar{m}(L_{\text{pt}})}{\bar{m}(L_0)} \mid_{\text{SF}} \frac{\bar{m}(L_0)}{\bar{m}(2L_0)} \mid_{\text{SF}} \frac{\bar{m}(2L_0)}{\bar{m}(L_{\text{had}})} \mid_{\text{GF}}. \quad (3.3)$$

The computation of (3.3) can be split in the following factors: the first term on the rhs is the PT matching, computed at NLO in the SF region with $L_{\text{pt}} = L_0/2^N \sim 65$ GeV, the second is the standard iterative procedure carried out with the polynomial interpolation of $\sigma_p(u)$ for $N = 4$ steps (thus gaining a factor 16 in the scale) given by

$$\frac{\bar{m}(L_{\text{pt}})}{\bar{m}(L_0)} \mid_{\text{SF}} = \prod_{i=1}^{N} \sigma_p(u_i), \quad \text{with} \quad \sigma(u_{i+1}) = u_i = \bar{g}^2(2^{-i}L_0), \quad (3.4)$$

the third factor (that could be included in the iteration above) represents the NP scheme matching since it is connecting the two coupling regions

$$\frac{\bar{m}(L_0)}{\bar{m}(2L_0)} \mid_{\text{SF}} = \sigma_p(u_0), \quad \text{with} \quad u_0 = \bar{g}^2(L_0) = 2.012. \quad (3.5)$$
The last term is then the ratio of the running from an hadronic scale to the scheme-switching scale. In order to have more flexibility in choosing \( L_{\text{had}} \) we take advantage of the non-perturbative RG functions and directly determine

\[
\bar{m}(2L_0) \bigg|_{GF} = \exp \left\{ - \int_{g(2L_0)}^{g(L_{\text{had}})} \frac{\tau_{NP}^{GF}(g)}{\bar{\beta}_{GF}^{NP}(g)} \, dg \right\}.
\]

Note that here we are computing an integral whose limits are the two scales we want to connect by RG evolution. They do not have to be any more related by an integer scaling factor \( s \), as it is being applied in the SSF recursion. In the present work, identifying the hadronic scale with the one corresponding to the most hadronic point\(^2\) that is covered by the SSF from \( u_{GF} = 5.3010 \), we obtain \( L_{\text{had}}/L_0 = 18.74(26) \). With this choice, the total range of scales covered by the non-perturbative running in both schemes is \( L_{\text{had}}/L_{pt} = 300(4) \) and finally the total RG running factor \( M/\bar{m}(L_{\text{had}}) = 0.9088(78) \).

\(^2\)note that this is not the final value defining \( L_{\text{had}} \)
4. Conclusions

We have computed the NP running quark mass in three-flavour QCD between $\sim 200\text{MeV}$ and $\sim 60\text{GeV}$ with an unprecedented sub-percent uncertainty. This is a major achievement compared to a similar determination in the past [7, 13]. In order to optimise the overall precision (in particular towards the hadronic scales), we have employed two different schemes equipped with a non-perturbative at an intermediate scale of $\sim 4\text{GeV}$. Another completely new results is given by the computation of the NP mass anomalous dimension for both SF and GF coupling regions allowing for a more flexible choice of the hadronic matching scale.

Acknowledgments

The simulations were performed on the Altamira HPC facility, the GALILEO supercomputer at CINECA (INFN agreement), Finisterrae-2 at CESGA and CERN. We thankfully acknowledge the computer resources and technical support provided by the University of Cantabria at IFCA, CESGA, CINECA and CERN. P.F. acknowledges financial support from the Spanish MINECO’s “Centro de Excelencia Severo Ochoa” Programme under grant SEV-2012-0249, as well as from the grant FPA2015-68541-P (MINECO/FEDER).
