Functional Dissection of Auxin Response Factors in Regulating Tomato Leaf Shape Development

Lingjie Wu, Zhendong Tian and Junhong Zhang*

Key Laboratory of Horticultural Plant Biology, Ministry of Education, Huazhong Agricultural University, Wuhan, China

The phytohormone auxin is involved in many aspects of plant growth and developmental processes. The tomato Aux/IAA transcription factor SlIAA9/ENTIRE/E plays an important role in leaf morphogenesis and fruit development, and the E gene encodes a protein from the Aux/IAA family of auxin response repressors. Both SlIAA9-RNAi transgenic and entire (e) mutant plants reduce the leaf complexity in tomato, but the underlying mechanism is not yet completely resolved. Auxin signaling is known to regulate target genes expression via Aux/IAA and ARFs (auxin response factors) transcriptional regulators. ARFs mediate a wide range of developmental processes. Through an Y2H (yeast two-hybrid) assay coupled with expression profiling of the SlARF genes family, we identified a group of ARFs: SlARF6A, SlARF8A, SlARF8B, and SlARF24. Pull-down and BiFC (Bimolecular Fluorescence Complementation) results demonstrated that these SIARFs interact with SlIAA9 in vitro and in vivo, and the e mutation altered the expression patterns of multiple SIARFs. The simple leaves of the e mutant were partially converted to wild-type compound leaves by VIGS (virus-induced gene silencing) of these four SIARFs. Furthermore, IAA content in these samples was significantly increased compared to the e mutant. In addition, SlARF6A and SlARF24 bound to the SlPIN1 promoter and act as transcriptional activators to regulate genes expression involved in leaflet initiation. It may also suggest that SIARFs regulate leaf morphology through direct binding to auxin-responsive genes in the absence of SlIAA9, providing an insight for the role of SIARFs in leaf shape development.

Keywords: auxin, development, leaf shape, SIARFs, SlIAA9, tomato

HIGHLIGHTS
We firstly found that SIARF6A, SIARF8A, SIARF8B, and SIARF24 could regulate tomato leaf development in a redundant manner; Furthermore, SIARF6A and SIARF24 bound to the SlPIN1 promoter to regulate genes expression involved in leaflet initiation.

INTRODUCTION
Leaves are one of the main organs of flowering plants, and exhibit a tremendous diversity in shape and size. The shape of leaves varies enormously within the same species and individual plants, and can be ascribed to ranging from simple to compound. Variation is one of the most conspicuous aspects of plant diversity in leaf shape. This diversity is often achieved by the adjustment of leaf

Abbreviations: ARF, auxin response factor; IAA, indole-3-acetic acid; LUC, firefly luciferase; qRT-PCR, quantitative real-time PCR; REN, renilla luciferase; VIGS, virus-induced gene silencing; YFP, yellow fluorescent protein.
blade dissection to form lobes or leaflets (Ben-Gera et al., 2012). Simple leaves comprise of a single continuous blade, whereas compound leaves are composed of multiple discontinuous blade units termed as leaflets (Koenig et al., 2009). Leaves are formed at the flanks of the shoot apical meristem (SAM). Following the initiation of new shoot morphogenesis, leaves establish the basic framework for shape and size. Subsequently, organogenesis of lateral appendages occurs through differentiation and expansion of leaf tissue (Shwartz et al., 2016). Furthermore, the wild type leaves consist of primary, secondary, and intercalary leaflets with lobed margins in tomato (Berger et al., 2009).

After the formation and differentiation of the leaf primordia in the SAM, the development of the leaf primordium occurs (Merelo et al., 2016). Previous studies have discovered that two mechanisms are involved in the development of the leaf primordia. The first occurs through mutual repression between KNOX proteins and ARP (AS1/RS2/PHAN) MYB-domain proteins (Waites et al., 1998; Tsiantis et al., 1999; Byrne et al., 2000; Ori et al., 2000). The second mechanism demonstrates that the formation of leaf delimitation is controlled by PINOID (PID) and auxin efflux carrier PIN-FORMED1 (PIN1) which mediates local auxin accumulation (Furutani et al., 2004). In leaf development, AS1 represses the expression of KNOX gene BP (BREVIPEDICELLUS), while the function of the local auxin maxima alongside AS1 remains partly dependent on BP regulation. The SHOOT MERISTEMLESS (STM) gene is needed for SAM formation and maintenance, which prevents AS1 gene expression in the meristem (Byrne et al., 2000). In addition, auxin activities and KNOX proteins might form a feedback loop to facilitate leaf meristem delimitation (Zgurski et al., 2005; Hay et al., 2006).

Studies have indicated that leaf development is coordinated by a cross-talk between different hormones (Shwartz et al., 2016) with auxin playing a crucial role. The precise distribution and location of auxin signaling regulates proper leaf development in a specific spatiotemporal developmental context (Bilsborough et al., 2011). The auxin maxima is concentrated on the leaflet initiation area in the development of tomato leaves, resulting in lamina growth patterns (Ben-Gera et al., 2016). Auxin acts as an inducer of organogenesis. There are postulated inhibitory fields around existing primordia which are thought to result from low concentrations of auxin (Reinhardt et al., 2003; de Reuille et al., 2006; Jonsson et al., 2006). Endogenous auxin levels and localization are altered in developing leaves leads to leaf simplification phenotypes (Shwartz et al., 2016). SlIAA9 is an auxin regulator belonging to the Aux/IAA transcription factors gene family. Not only do SlIAA9-RNAi plants display simple leaves and parthenocarpy instead of compound leaves and seeded fruit characteristic typically seen from wild type (AC), but also the silenced plants have auxin-related growth alterations (Wang et al., 2005). The adjustment of Aux/IAA and SIARF genes and the downregulation of MADS box genes mediate fruiting, and early fruit development is regulated by the regulatory and metabolic events both in the absence and presence of pollination/fertilization (Wang et al., 2009). Meanwhile, tomato e mutant is reported as a single-base deletion in the coding region of the SlIAA9 gene and exhibits single based lamina with primary leaves partially fused (Zhang et al., 2007), E mRNA is discovered throughout the leaf margin (Koenig et al., 2009). Thus, SlIAA9 plays a role in limiting lamina growth between developing leaflets by locally inhibiting auxin responses. GOB (GOBLET) encodes a NAC-domain transcription factor and its expression is intact in the simplified leaves of entire (e) mutants in tomato. Leaves of single gob or e mutants formed only primary leaflets, and downregulation of both GOB and E (SlIAA9) contributed to the complete abolishment of leaflet initiation. This indicates those auxin response and leaflet morphogenesis are modulated by GOB and E via partly redundant pathways (Blein et al., 2008; Ben-Gera et al., 2012). The tomato clau (clausa) mutant exhibits elaborate compound leaves. CLAU might negatively regulate the expression of GOB, and GOB expression is up-regulated in the compound leaf mutant lyr (lyrate). However, the enhancement of the clau phenotype by lyr indicates that clau and lyr affect GOB and leaf development in different pathways (Bar et al., 2015). Higher expression of LA (LANCEOLATE) during the early stages of leaf development result in a simpler leaf shape, likely regulated in part by gibberellic acid (GA) levels (Yanai et al., 2011). The expression of TKn1 in the leaf primordium is needed for compound structure formation (Hareven et al., 1996). miR164 negatively regulates GOB-like genes, and leaf-specific overexpression of miR164 induces a loss of secondary leaflet initiation and smooth leaflet margins (Berger et al., 2009). The miR160 targets a group of ARFs which antagonize lamina growth and auxin response in conjunction with E plants. Leaflet separation is assured by different type of auxin signal antagonists (Ben-Gera et al., 2016). Auxin, E, GOB, Lyr, and mir160-targeted ARFs collaborate to specify leaflet initiation and promote leaflet separation (Kimura et al., 2008). However, the underlying molecular mechanism of how functional redundancies among SIARF proteins regulate leaf shape development in tomato remains an open question.

Aux/IAA protein can repress ARF transcription factors via protein to protein interaction (Tiwari et al., 2001), and the degradation of Aux/IAA proteins can relieve ARF proteins for auxin-responsive gene transcription (Tan et al., 2007). SlIAA9 protein mediates leaf morphogenesis by participating in auxin signal transduction (Wang et al., 2005; Goetz et al., 2007). Furthermore, ARFs represent essential factors in the transduction of auxin signaling, and multiple ARFs were previously shown to interact with IAA9 (Korasick et al., 2014; Piya et al., 2014). In this work, we showed that tomato plants with a silenced SlIAA9 complex change from simple to complex leaf morphology, providing an insight for the significant role of functional redundancies among SIARF proteins in leaf morphogenesis. This indicates that SIARFs may mediate phenotypic plasticity in foliar organogenesis, and that further studies on SIARFs may reveal insights into the evolution of plant leaves.

**MATERIALS AND METHODS**

**Plant Materials and Growth Conditions**

Tomato plants (Solanum lycopersicum cvs. Ailsa Craig) and e mutants in the Ailsa Craig background were grown under
standard greenhouse conditions (14 h day/10 h night cycle, 25–20°C day/night temperature, 60–75% relative humidity). The e mutation plants prepared for VIGS assay were kept in a growth chamber (16 h day/8 h night cycle, 20–22°C, 50% relative humidity).

**qRT-PCR**

Total RNA from all samples was isolated using the TRIzol reagent (Invitrogen, United States). The RNA was treated with DNase I at 37°C for 30 min to remove residual genomic DNA. Using the HiScript II 1st cDNA Synthesis Kit (Vazyme, China) to synthesis the first-strand cDNA according to the manuscript's protocol. The cDNA concentrations were normalized according to actin expression levels for qRT-PCR analysis. qRT-PCRs were performed using the power SYBR Premix Ex Taq kit and the TaKaRa two-step method (TaKaRa, Japan). PCR products were quantified using the Roche Light Cycler 480 Real-Time PCR Detection System and the SYBR Green I Master Kit (Roche, Switzerland). The PCR program was as follows: 95°C for 45 s; 40 cycles of 95°C for 10 s, 58°C for 25 s, and 72°C for 20 s. For all qRT-PCR experiments, at least three biological replicates were performed, and each reaction was run in triplicate.

**Yeast Two-Hybrid Assay (Y2H)**

For yeast two-hybrid assay, the full-length coding sequence of each SlARF (Supplementary Table S1) and SlIAA9 (Solyc04g076850) were cloned from various tissues of Ailsa Craig. Recombinant plasmid pGBK7-SlIAA9 and pGADT7-SlARF were constructed by inserting SlIAA9 and SlARF into pGBK7 and pGADT7 vectors separately. The two plasmids were co-transformed into the yeast strain AH109 by small-scale yeast transformation method. The transformants grew on the SD/-Trp/-Leu drop-out medium. After colony formation, transformants were transferred to SD/-Leu/-Trp/-His/-Ade drop-out medium with 40 µg/ml G418. The sample leaves were frozen in liquid nitrogen. Three replicates were prepared for each leaf sample. The biomass for each replicate was 0.1 g. Subsequently, IAA extraction was performed using the UFLC-ESI-MS/MS method following the published protocol (Liu et al., 2012).

**Bimolecular Fluorescence Complementation (BiFC) Assays**

The SlIAA9 ORF without the stop codon was constructed using the pUC-SPYNE/pSPYNE-35S vector to produce SlIAA9-YFP fusion proteins, and the SlARF ORFs without the stop codon were cloned into the pUC-SPYCE/pSPYCE-35S vector to generate SlARFs-YFP fusion proteins. Protoplasts were extracted from 1-week-old Arabidopsis Col-0 suspension cell culture and the corresponding constructs were co-transformed into them. The transfected protoplasts were assayed for fluorescence after 12–18 h of expression. All primer sequences used in this analysis are listed in Supplementary Table S2.

**In Vitro Pull-Down Assay**

The recombinant plasmids were transformed into BL21(DE3)pLysS chemically competent cells. SlIAA9-GST was purified with Glutathione Agarose (Thermo Fisher Scientific, United States) according to the company manual instruction. MBP, MBP-SlARF6A, MBP-SlARF8A, MBP-SlARF8B, and MBP-SlARF24 were purified as fusion proteins immobilized with amylose resin (New England Biolabs, United States) following standard protocols. Five micrograms of GST-SlIAA9 protein were pre-incubated with 10 µL pre-washed amylose resin in 150 µL incubation buffer (1 mM NaCl, 20 mM MgCl₂, 0.2% Triton X-100, and 0.1 M Hepes at pH 7.2) for 1 h at 4°C. The resin was collected by centrifugation and washed five times with washing buffer (20 mM Tris- HCl at pH 7.5, 300 mM NaCl, 0.1 mM EDTA, 0.5% Triton-X100). The pull-down proteins were detected by western blot with an α-GST antibody (Thermo Fisher Scientific, United States). All primer sequences used in this analysis are listed in Supplementary Table S2.

**VIGS Assays**

To generate the VIGS constructs, 208 bp, 157 bp, and 238 bp fragments of the gene SlARF6A, SlARF8A, and SlARF24 was amplified by sequence-specific primers (Supplementary Table S2), respectively. Since SlARF8A and SlARF8B are highly homologous, the fragment from SlARF8A was used to silence both SlARF8A and SlARF8B. All of the pTRV1, pTRV2, pTRV2-PDS, and pTRV2-host target genes were transformed into the Agrobacterium tumefaciens strain GV3101 by electroporation. Cultures containing the pTRV1 and pTRV2 vectors were mixed in a 1:1 ratio, either individually or simultaneously (pTRV2-PDS, pTRV2, pTRV2-SlARF6A, pTRV2-SlARF8A, pTRV2-SlARF24, pTRV2-SlARF6A/8A, pTRV2-SlARF6A/24, pTRV2-SlARF6A/24, pTRV2-SlARF6A/8A/24). These were used to infect cotyledon of tomato e mutant plants before the emergence of true leaves. The infected plants were transferred to a growth chamber at 16 h day/8 h night cycle, 20–22°C and 50% RH. The phenotypes were analyzed 6–7 weeks after inoculation. The VIGS method was following the published protocol (Velasquez et al., 2009).

**Quantification of the Free IAA Using UFLC-ESI-MS/MS**

The sample leaves were frozen in liquid nitrogen. Three replicates were prepared for each leaf sample. The biomass for each replicate was 0.1 g. Subsequently, IAA extraction was performed by ESI-MS/MS following the published protocol (Liu et al., 2012).

**Yeast One-Hybrid Assay (Y1H)**

For yeast one-hybrid assay, the –1479 bp fragment (upstream from the start codon) from the SIPIN1 (Solyc03g118740) promoter was amplified from Ailsa Craig genomic DNA and cloned into the pAbAi vector (Clontech). Recombinant plasmid pAbAi-SIPIN1 and pGADT7-SlARF were co-transformed into the yeast strain Y1HGold (Clontech) by small-scale yeast transformation method respectively. The transformants were plated on the SD/-Ura drop-out medium. Colonies were picked and diluted in sterile ddH₂O to an OD600 of 0.5, and 3 µl of suspension was spotted on SD/-Ura/-Leu drop-out medium with or without AbA antibiotic at 30°C. Both pGAD-p53+p53-AbAi (positive control) and pGADT7+p1-AbAi (negative control) were included.
Transient Expression in Tobacco Leaves
The full-length SIARFs ORF were amplified and cloned into the effector vector, pGreen II 62-SK. A –1479 bp fragment (upstream from the start codon) from the SLPIN1 promoter was amplified and cloned into the reporter vector, pGreen II 0800-LUC. Both the effector and reporter vector were respectively co-transformed into the Agrobacterium tumefacions strain GV3101 cells with the pSoup vector, then infiltrated into N. benthamiana young leaves and incubated 72 h in the dark. LUC and REN were analyzed using the dual luciferase assay reagents (Promega) with an Infinite M200 (Tecan). All primers used in this analysis are listed in Supplementary Table S2.

RESULTS
SIAA9 Interacts With Multiple SIARF Proteins
In order to dissect the mechanism of SIAA9 regulating leaf shape development in tomato, a yeast two-hybrid (Y2H) screening was performed to identify the SIAA9 interacting proteins from tomato cDNA Y2H library. After several screens, SIARF24 was screened out (Supplementary Table S3). To identify more SIARFs that may participate in this pathway, the full-length coding sequences of 15 SIARFs, including the candidate SIARF24 previously identified, were isolated and inserted into the yeast two hybrid vector pGADT7, including SIARF1, SIARF2B, SIARF3, SIARF4, SIARF5, SIARF6A, SIARF6B, SIARF8A, SIARF8B, SIARF9A, SIARF9B, SIARF10A, SIARF10B, and SIARF16A. The recombinant plasmid pGBK7-SIAA9 and pGADT7-SIARF7 were co-transformed into the yeast, respectively. Specifically, we observed that yeast cells containing pGBK7-SIAA9 and pGADT7-SIARF7 were mated with pGADT7-SIARF6A, pGADT7-SIARF8A, pGADT7-SIARF8B, and pGADT7-SIARF24 respectively to grow under selection conditions (Figure 1A). This result suggests that SIAA9 may interact with SIARF6A, SIARF8A, SIARF8B, and SIARF24 in yeast cells.

Subsequently, the interactions between SIAA9 and SIARF6A, SIARF8A, SIARF8B, and SIARF24 were examined using BiFC in Arabidopsis mesophyll protoplasts. We transformed the Arabidopsis Col-0 protoplasts with SIAA9-YFP\(^N\)/SIARF6A-YFP\(^C\), SIAA9-YFP\(^N\)/SIARF8A-YFP\(^C\), SIAA9-YFP\(^N\)/SIARF8B-YFP\(^C\), SIAA9-YFP\(^N\)/SIARF24-YFP\(^C\), and SIAA9-YFP\(^N\)/YFP\(^C\). Strong YFP fluorescence signal was detected throughout the nucleus when SIAA9-YFP\(^N\) was co-expressed with SIARF6A-YFP\(^C\), SIARF8A-YFP\(^C\), SIARF8B-YFP\(^C\), and SIARF24-YFP\(^C\), whereas no fluorescence was detected in the control cells (Figure 1B). These results indicate that SIAA9 might interact with multiple SIARF proteins in vivo.

In order to further confirm that the SIAA9 protein could directly interact with SIARF6A, SIARF8A, SIARF8B, and SIARF24 proteins, a pull-down assay was performed. In this experiment, SIARF6A, SIARF8A, SIARF8B, or SIARF24 fused to maltose binding protein (MBP) immobilized on amylose-agarose beads were used as bait against GST-SIAA9 fusion proteins. As shown in Figure 1C, GST-SIAA9 could be pulled down by MBP-SIARF6A, MBP-SIARF8A, MBP-SIARF8B, as well as MBP-SIARF24, but not by MBP alone, demonstrating that SIARF6A, SIARF8A, SIARF8B, and SIARF24 proteins physically interact with SIAA9 in vitro.

The e Mutation Alters the Expression Patterns of Multiple SIARFs
A previous study showed that the basal gene expression of SIAA9 was high in roots, leaves, flowers, and fruits (Wang et al., 2005). For comparative purposes, qRT-PCR was performed to investigate the expression levels of SIAA9 in wild type root, stem, leaf, flower, and fruit tissue (Supplementary Figure S1). These results indicated that SIAA9 expressed in all tissues, but exhibits lower expression at the mature green (MG) stage in fruit tissue.

We analyzed the expression levels of the SIARF genes family in wild type (compound leaves) and e mutant (simple leaves) leaves. The expression levels of SIARF1, SIARF2A, SIARF2B, SIARF5, and SIARF18 in leaves of the e mutant were induced 2.14-, 5.79-, 5.90-, 3.19-, and 2.73-fold more than that of those in wild type leaves. While the SIARF3, SIARF6A, SIARF6B, SIARF7B, SIARF10A, SIARF10B, SIARF16A, SIARF16B, SIARF19, and SIARF24 showed decreased expression corresponding to 0.05-, 0.48-, 0.45-, 0.47-, 0.15-, 0.15-, 0.44-, 0.01-, 0.05-, and 0.48-fold, respectively. Other SIARFs showed no significant difference (Figure 2). These results establish that multiple SIARFs are regulated in the absence of SIAA9 in the auxin signaling model. This is particularly indicated for the SIARF16B gene, which might have a unique and significant function in this pathway. In addition, the expression levels of SIARF6A, SIARF8A, SIARF8B, and SIARF24 displayed varying degrees of attenuation in e mutant plants compared to wild type plants, supporting the hypothesis that the SIARF6A, SIARF8A, SIARF8B, and SIARF24 interaction with SIAA9 has compromised biological function in e mutant plants.

Diminished Expression of Multiple SIARFs Can Rescue the Leaf Phenotype of Tomato e Mutation
The genetic mechanism by which SIAA9 regulates leaf shape development in tomato was examined by silencing SIARFs in the e mutant background. Using TRV-mediated VIGS we carried out a functional characterization assay of the four candidate SIARF genes identified through the previous expression analysis. SIARF8A and SIARF8B share 82% amino acid identity (Supplementary Figure S2), therefore both genes were silenced in one VIGS construct. There was no detectable change in leaf shape after individually silencing pTRV2-SIARF6A, pTRV2- SIARF8A, and pTRV2-SIARF24 (Figure 3A). Gene expression analysis showed that the mRNA levels of SIARF6A, SIARF8A, SIARF8B, and SIARF24 were reduced to approximately 43%, 48%, 49%, and 51% respectively compared to the empty vector control (Figure 3B). Functional redundancies among ARF proteins have been described in Cucumis sativus, A. thaliana, and S. lycopersicum (Okushima et al., 2005; Liu and Hu, 2013; Hao et al., 2015). In accordance with this redundancy, we inoculated pTRV2-SIARF6A, pTRV2-SIARF8A, and pTRV2- SIARF24 constructs into e mutant plants using double or triple
co-cultures of *Agrobacterium*. Interestingly, 80%, 73%, and 77% of the *e* mutant plants infiltrated with *Agrobacterium* triple co-cultures expressing *pTRV2-SlARF6A/8A/24* were partially converted to compound leaves in three replicate experiments (Table 1). Meanwhile, the mRNA levels of *SlARF6A*, *SlARF8A*, *SlARF8B*, and *SlARF24* in the *e* mutant plants inoculated with the *Agrobacterium* co-cultures of *pTRV2-SlARF6A/8A/24* were reduced to approximately 60%, 57%, 69%, and 64% compared with the empty vector control, respectively (Figure 3C). Furthermore, the gene expression of other members of the *SlARF* family were not significantly changed after silencing the four candidate *SlARFs* (Supplementary Figure S3). Moreover, the fifth leaves of silencing of candidate *SlARF* genes in tomato *e* mutation were observed, the results presented that *e* mutant plants inoculated with *pTRV2-SlARF6A/8A/24* triple combination cultures were partially converted to wild-type compound leaves, which generating more leaflets (Figure 4A). The total leaflets on the mature first five leaves of the *pTRV2-SlARF6A/8A/24* inoculated plants were significantly increased compared to the *e* mutant plants (Figure 4B). The double co-cultures *pTRV2-SlARF6A/8A*, *pTRV2-SlARF6A/24*, and *pTRV2-SlARF8A/24* could not restore the development of compound leaves (Figure 4A and Table 1) despite that the expression analysis revealed the target genes were down-regulated (Figure 3B). These results illustrated that simultaneously silencing of these four genes could restore the compound leaf shape in *e* mutant plants, and suggested functional redundancies among *SlARF* proteins in regulating tomato leaf shape development.

To analyze whether these phenotypic changes are regulated by auxin, the free IAA levels were quantified using UFLC-ESI-MS/MS. IAA levels of young leaves that had all four *SlARF* silenced reached 20.14 ng/g, which were significantly higher than the *e* mutant plants (13.14 ng/g). Interestingly, the concentration of IAA in *e* mutant was observed to have a higher basal level than
To determine whether SlARF6A and SlARF24 function as activator or repressor, we used a LUC (dual luciferase) assay to test how SlARF6A and SlARF24 interact with the SlPIN1 promoter. The same fragment of SlPIN1 used in the Y1H assay was introduced into the pGreen II 0800-LUC vector to generate the reporter construct (Figure 5C). The effector and reporter construct were transiently expressed in tobacco leaves and the relative LUC activity was determined. This result revealed that LUC activity was 2.29- and 1.69-fold higher in the presence of SlARF6A and SlARF24 effector and reporter construct than in the negative control (Figure 5C), implying that both SlARF6A and SlARF24 may function as a transcriptional activator. This result revealed that the cis-element from the SlPIN1 promoter was bound by SlARF6A and SlARF24.

**DISCUSSION**

**SlARF Proteins Regulate Tomato Leaf Shape in a Functionally Redundant Manner**

Over the past 10 years, SlIAA9 has been shown to be involved in fruit development, leaf morphogenesis, and fruit parthenocarpy in *A. thaliana* and *S. lycopersicum* (Wang et al., 2005, 2009; Goetz et al., 2007). In this study, we aimed to identify interacting partners of SlIAA9. The initial Y2H assay identified several candidates, including Aux/IAA proteins, ubiquitin related proteins, gibberellin beta-hydroxylase protein, MADS box interactor-like protein, and SlARF24 (Supplementary Table S3). More SlARFs (SlARF6A, SlARF8A, SlARF8B, and SlARF24) were induced by auxin through promoting auxin response.

**Downregulation of Multiple SlARFs Can Rescue the Expression of Leaf Shape Determining Genes**

The leaf growth and development in tomato is likely driven by the leaf shape related genes (Hareven et al., 1996; David-Schwartz et al., 2009; Illing et al., 2009; Yanai et al., 2011; Pinon et al., 2013). Subsequently, the transcript levels of these leaf shape related genes in tomato were evaluated through qRT-PCR. The *SlPIN1* and *phan* expression in *pTRV2-SlARF6A/8A24* silenced plants was induced 1.8- and 2.5-fold compared to *e* mutant plants, respectively. In contrast, the expression level of *LYR* was reduced by 4.6-fold compared to *e* mutant plants (Figure 5A). Thus, after silencing the four SlARFs in *e* mutant, the expression of those genes were reverted back to wild type level. We hypothesize that SlARF proteins may regulate leaf shape development by regulating the expression of *SlPIN1*.

**SIARF6A and SIARF24 Bind to the SlPIN1 Promoter**

To investigate the relationship between the candidate SlARFs proteins and *SlPIN1* promoter, a fragment of the *SlPIN1* promoter 1,479 bp upstream from the start codon was used in an Y1H assay (Figure 5B). Y1H results demonstrated that this fragment could interact with SlARF6A and SlARF24 protein, confirming that SlARF6A and SlARF24 protein recognize the cis-element in the SlPIN1 promoter in yeast.

To determine whether SlARF6A and SlARF24 function as activator or repressor, we used a LUC (dual luciferase) assay to test how SlARF6A and SlARF24 interact with the SlPIN1 promoter. The same fragment of SlPIN1 used in the Y1H assay was introduced into the pGreen II 0800-LUC vector to generate the reporter construct (Figure 5C). The effector and reporter construct were transiently expressed in tobacco leaves and the relative LUC activity was determined. This result revealed that LUC activity was 2.29- and 1.69-fold higher in the presence of SlARF6A and SlARF24 effector and reporter construct than in the negative control (Figure 5C), implying that both SlARF6A and SlARF24 may function as a transcriptional activator. This result revealed that the cis-element from the SlPIN1 promoter was bound by SlARF6A and SlARF24.

SIARF24) were further found to interact with SIIA9 in vivo and in vitro (Figure 1), indicating that other SIARFs may play redundant roles with SIARF24 in regulating leaf development. SIIA9 and miR160-targeted ARFs SIARF10A, SIARF10B, or SIARF17, appear to partially act in a functionally redundant manner, but remain necessary for local inhibition of lamina growth between initiating leaflets (Ben-Gera et al., 2016). However, the elucidation of the molecular mechanism on how these functional redundancies among SIARF proteins regulate tomato leaf shape has been hampered by complexity of the protein in planta. Understanding the mechanisms involved in leaf shape development in tomato can provide new insights into understanding these same mechanisms in other species such as A. thaliana, Glycine max, and C. hirsuta.

SIARFs may regulate leaf morphology through binding to the promoter of SIPIN or other auxin-responsive genes in the absence of SIIA9 (Figure 5). SIARF8 and SIIA9 proteins, together with another unknown protein, may form a regulatory complex to control fruiting and growth, offering a possible explanation for the role of SIIA9 in parthenocarpy (Goetz et al., 2007). SIARF6 and SIARF8 also play conserved roles in regulating development and growth of flower and vegetable organs in dicots (Liu et al., 2014). The Osarf24-1 mutant presents reduced sensitivity to aberrant auxin signaling and auxin-deficient phenotypes (Sakamoto, 2013). Here, we firstly found that SIARF6A, SIARF8A, SIARF8B, and SIARF24 could regulate tomato leaf development in a redundant manner.

### SIARF Genes Play Distinct and Vital Roles in the Auxin Signaling Model

It has been illustrated that several SIARF genes might serve unique functions in tomato development. SIARF2A functions in the regulation of tomato fruit ripening as a recognized auxin signaling component (Breitel et al., 2016). Down-regulation of SIARF4 results in a dark-green fruit phenotype with increased plastids densities (Jones et al., 2002). Furthermore, SIARF4 involves in the control of sugar metabolism during fruit development in tomato (Sagar et al., 2013). Both auxin and gibberellin responses are modulated by SIARF7 during fruit formation and development in tomato (De Jong et al., 2011). Compared with wild type fruits, the fruits of SIARF7-RNAi transgenic lines presented seedless, heart-shaped, and thick pericarp phenotypes in tomato (De Jong et al., 2009). Cell division is negatively regulated by SIARF9 during early fruit development in tomato (De Jong et al., 2015). Primexine...
formation is modulated by ARF17, which is crucial for pollen wall patterning, partially through regulation of CalS5 gene expression in *Arabidopsis* (Yang et al., 2013). A 165-bp deletion in ARF18 gene simultaneously affects silique length and seed weight in polyploid rapeseed (Liu et al., 2015). Moreover, there are functional redundancies among ARF proteins in *Cucumis sativus*, *A. thaliana*, and *S. lycopersicum* (Okushima et al., 2005; Liu and Hu, 2013; Hao et al., 2015). A constitutive expression pattern was exhibited in almost all of the ARF genes in cucumber (Liu and Hu, 2013). In *A. thaliana*, *arf7 arf19* double mutant presented an obvious auxin-related phenotype that were not detectable in the single mutant, suggesting that there are functional redundancies between ARF7 and ARF19 proteins (Okushima et al., 2005). Simultaneous silencing of *SIARF2A* and *SIARF2B* genes led to severe ripening inhibition, clarifying a functional redundancies between SIARF2A and SIARF2B proteins (Hao et al., 2015). Our VIGS results provided evidence that functional redundancies among SIARF proteins resulted in the change from a simple leaf to a complex one in tomato e mutant plants (*Figure 3*). Due to the far evolutionary relationship among candidate SIARFs, clarifying there are functional compensation among the candidate SIARFs. It should be noted that this study has only examined the function of *SIARF6A*, *SIARF8A*, *SIARF8B*, and *SIARF24*, because only 15 tomato SIARF genes were isolated from the full-length cDNA sequences out of the 22 SIARF genes family. It has been reported that SIARF17 and SIIAA9 do not interact in yeast (Ben-Gera et al., 2016). There are still another six SIARF genes that have not yet been characterized by us. Our result showed that the expression levels of *SIARF16B* were 0.01-fold less in leaves of the e mutant compared to those in wild type. A previous study describes that the *Pto-ARF16* was affected by *Pto-miR160a* associated with tree growth and wood property traits in *Populus tomentosa* (Tian et al., 2016). In *A. thaliana*, ARF10 and ARF16 were targeted by miR160 to control the formation of root cap cell, and miR160-uncoupled production of ARF16 reflected pleiotropic effects (Wang et al., 2005). Thus, we hypothesize that *SIARF16B* is regulated in the absence of SIIA9 in the auxin signaling model, which needs to further evaluated with additional experiments. Consequently, the e mutation likely alters the expression patterns of other SIARF genes through this mechanism. The hetero-dimerization between Aux/IAA and ARF proteins likely able to play unique cellular functions (Piya et al., 2014). However, how the SIIA9-SIARFs complex functions during tomato leaf development is still not yet completely resolved.

**A Proposed Model of SIIA9 Complex in the Control of Tomato Leaf Forms**

We chose several leaf shape related genes in *A. thaliana* and *S. lycopersicum* to evaluate whether these genes could
FIGURE 5 | Quantitative real-time PCR analysis of leaf shape related genes and SIARF6A and SIARF24 bind to the SlPIN1 promoter. (A) The expression of SlPIN1, AS1, and phan in the leaves of e mutant, silencing of all the four SIARF genes materials and wild type plants. (B) Yeast-one hybrid (Y1H) assay of SIARF6A and SIARF24 binding to SlPIN1 promoter. The yeast cells grown on SD/-Ura/-Leu and SD/-Ura/-Leu + 15 ng ml⁻¹ AbA. (C) Transcription activity assay in tobacco to examine the interaction between candidate SIARFs and SlPIN1 promoter. The schematic diagrams constructs used for the dual LUC assay; REN (Renilla luciferase), a control for activity normalization; PG, the empty vector of pGreen II 62-SK. Standard errors (SE) are shown (n = 3).

FIGURE 6 | A proposed model of SlIAA9 complex in the control of tomato leaf forms. SlIAA9 and SIARF6A, SIARF8A, SIARF8B, and SIARF24 proteins, form a regulatory complex, which can directly block leaflet initiation genes or act indirectly by preventing SIARFs from functioning as transcriptional activators. In the absence of SlIAA9, SIARFs may regulate leaf growth and development through direct binding to the promoter of SlPIN1 or other auxin-responsive genes, which promoted auxin response.

regulate the development of leaf shape. As a result, the expression levels of SlPIN1, phan, and L1R in leaves having SIARF6A, SIARF8A, SIARF8B, and SIARF24 simultaneously silenced through VIGS were restored to levels similar to those in wild-type plants (Figure 5A). The IAA levels in leaves having those same four SIARFs silenced were significantly increased compared to the control (Figure 4C). Auxin acts as a positional cue during leaf organogenesis, and auxin efflux carrier PIN1 is one of the main contributors to auxin localization (Reinhardt et al., 2003; Cheng et al., 2007). PIN1 localizes on the periphery of apical meristems directing auxin to convergence points, where auxin maxima is formed, subsequently auxin becomes directed subepidermally at the leaf initiation site to regulate leaf development (Heisler et al., 2005; Martinez et al., 2016). Genetic analyses have also demonstrated that PIN1 is required for leaflet initiation in compound leaves (Barkoulas et al., 2008). Accordingly, the cis-element of SlPIN1 was used for deep analysis. The cis-elements from SlPIN1 promoter were recognized and bound specifically by SIARF6A and SIARF24 in yeast and plants (Figure 5).

Here, we propose that SIARF6A and SIARF24 may regulate leaf growth and development through direct binding to the SlPIN1 promoter. However, the effects of enhanced SlPIN1 transcription still needs to be further evaluated. This enhanced transcription may result to increased expression of SlPIN1 protein, changed SlPIN1 protein modification, or shift the location of SlPIN1.

Our data provide an insight to suggest that SIARF proteins work with SlIAA9 in a functionally redundant manner to dictate leaf shape. We propose that SlIAA9 interacts with multiple SIARF proteins to promote the formation of a regulatory complex which can directly block leaflet initiation genes. We also assume that this complex may act indirectly by preventing SIARFs from
functioning as transcription activators. In the absence of SIIA9, SIARFs may regulate leaf growth and development through direct binding to the promoter of SPLIN1 or unknown X genes induced by auxin (Figure 6). Future studies will be directed to dissect the relationship between SIIA9 and SIARF6A, SIARF8A, SIARF8B, and SIARF24. We also intend to clone other SIARF genes to ascertain whether SIIA9 has additional interactors with unique biological functions.

CONCLUSION

In conclusion, this study posits a proposed molecular mechanism of SIIA9 complex in the control of tomato leaf forms (Figure 6). Our results firstly demonstrate that SIARF6A, SIARF8A, SIARF8B, and SIARF24 directly interact with SIIA9, and the simple leaves of the e mutant are partially converted to wild-type compound leaves by silencing of all the four SIARFs. Meanwhile, SIARF6A and SIARF24 bind to the SPLIN1 promoter to regulate gene expression involved in leaflet initiation. Further studies are still needed to explore the underlying mechanism of SIARF proteins in modulating tomato leaf shape.
