Behçet’s disease · Rheumatoid arthritis · Multiple sclerosis · Nationwide population study

\textbf{Abstract}

\textbf{Background:} No epidemiologic study has previously reported on the associations among Behçet’s disease (BD) and autoimmune disorders. \textbf{Objectives:} To investigate the association between BD and the autoimmune disorders multiple sclerosis and rheumatoid arthritis. \textbf{Methods:} Medical records of patients newly diagnosed with BD (n = 6,214) in 2012–2017 were analyzed using data entered into a large, nationwide database from 2007 to 2017. An age- and sex-matched control population of individuals without BD was sampled at a ratio of controls:BD cases of 3:1 (n = 18,642). Both cohorts were analyzed for the presence of multiple sclerosis or rheumatoid arthritis within a minimum of 5 years prior to their BD diagnosis. \textbf{Results:} Patients with BD had significantly higher odds ratios (ORs) for multiple sclerosis (8.85 [95% CI 2.36–33.17]) and rheumatoid arthritis (4.62 [95% CI 3.35–6.35]) than the control group after adjustment for diabetes mellitus, hypertension, and dyslipidemia. BD patients aged <40 years had a higher proportion of rheumatoid arthritis (OR 23.91, 95% CI 5.50–103.9) than older patients (OR 3.96, 95% CI 2.83–5.54). \textbf{Conclusion:} Our results suggest that BD is associated with multiple sclerosis and rheumatoid arthritis.

\textbf{Introduction}

Behçet’s disease (BD), synonymous with Adamantiades-Behçet disease and Behçet’s syndrome, is a rare systemic inflammatory disease ranging from 0.1 per 100,000 population in the USA [1] to 664 per 100,000 population estimated for northern Jordan [2]. A meta-analysis found the prevalence of BD to be 10.3 (95% confidence interval [CI] 6.1–17.7) per 100,000 population globally [3]. In 2017, a large population-based study was conducted to investigate the prevalence and mortality rate of BD in South Korea between 2006 and 2015. The study found the annual incidence rate to be 3.97 per 100,000 person-years, which was much higher than in other countries [4].

Behçet’s Disease and Autoimmune Diseases

BD is classified as an autoinflammatory disorder because of the absence of pathogenic autoimmune T and B cell responses. Autoinflammatory disorders are characterized by an abnormally increased inflammatory response that is mediated predominantly by the cells and molecules of the innate immune system [5]. The clinical features of BD include oral and genital aphthous ulcers, uveitis, a positive skin pathergy test, papulopustular or acne-like lesions, and arthritis, features which are also observed in other autoinflammatory disorders [6].

Unlike monogenic autoinflammatory disorders, BD is considered a multifactorial or acquired autoimmune disorder. Several genetic factors are suspected to have a pathogenic influence, including the genes encoding human leukocyte antigen (HLA)-B51 [7]. Epigenetic alterations are also reported in patients with BD [8] and environmental factors such as microorganisms [9–11], vitamin D deficiency [12, 13], and smoking [14–19] are associated with BD. BD is considered to be a hybrid of autoinflammatory and autoimmune disorders, or a “mixed-pattern disease” [6]. The strong association of HLA-B51 with BD might explain an adaptive immunity component that is driven by lymphocytes with antigen receptors and has decisive functions in autoimmune disorders [20].

This study investigated the associations of autoimmune disorders, including multiple sclerosis and rheumatoid arthritis, with BD. We used a nationwide, population-based cohort design and data from the Korean National Health Insurance (KNHI) database.

Materials and Methods

For further details, see the online supplementary material (www.karger.com/doi/10.1159/000514634) and Figure 1.

Results

Characteristics of the Study Population

Of the 6,214 patients, 3,855 were female (62.0%) and 2,359 were male (38.0%). Mean age was 46.9 ± 13.2 years, with most participants (54.8%) aged between 40 and 59 years. Because we extracted a control group matched for age, sex, and year of claim, the characteristics of the control group were the same as those of the BD group (Table 1).

Positive Associations between Autoimmune Disorders and BD

The analysis of claims data entered from 2007 to 2017 at least 5 years prior to baseline showed a proportion for multiple sclerosis (0.14%) and rheumatoid arthritis (1.63%) in the BD group that was significantly higher than in the control group (0.02 and 0.34%, respectively). The comorbid diseases diabetes mellitus, hypertension, and dyslipidemia were significantly higher in the BD group (Table 1).

Odds ratios (ORs) for multiple sclerosis and rheumatoid arthritis in the BD group were 9 (95% CI 2.44–33.24) and 4.78 (95% CI 3.49–6.55), respectively. Increased ORs for multiple sclerosis (8.85; 95% CI 2.36–33.17) and rheumatoid arthritis (4.62; 95% CI 3.35–6.35) in the BD group were consistent after adjustment for other comorbid diseases (Table 2).

Subgroup Analysis

The ORs for multiple sclerosis and rheumatoid arthritis were further analyzed according to age, sex, and the presence of diabetes mellitus, hypertension, or dyslipidemia (Fig. 2).
Table 1. Demographics of study population

|                          | Controls (n = 18,642) | Patients with Behçet’s disease (n = 6,214) | p value |
|--------------------------|------------------------|------------------------------------------|---------|
| Sex                      |                        |                                          |         |
| Male                     | 7,077 (38.0)           | 2,359 (38.0)                             |         |
| Female                   | 11,565 (62.0)          | 3,855 (62.0)                             |         |
| Calendar year            |                        |                                          |         |
| 2012                     | 2,823 (15.1)           | 941 (15.1)                               |         |
| 2013                     | 2,871 (15.4)           | 957 (15.4)                               |         |
| 2014                     | 2,946 (15.8)           | 982 (15.8)                               |         |
| 2015                     | 3,318 (17.8)           | 1,106 (17.8)                             |         |
| 2016                     | 3,573 (19.2)           | 1,191 (19.2)                             |         |
| 2017                     | 3,111 (16.7)           | 1,037 (16.7)                             |         |
| Age group                |                        |                                          |         |
| <40 years                | 5,466 (29.3)           | 1,822 (29.3)                             |         |
| ≥60 years                | 2,955 (15.9)           | 985 (15.9)                               |         |
| Comorbidities            |                        |                                          |         |
| Diabetes mellitus        | 1,126 (6.0)            | 458 (7.4)                                | 0.0002  |
| Hypertension             | 3,886 (20.9)           | 1,533 (24.7)                             | <0.0001 |
| Dyslipidemia             | 3,859 (20.7)           | 1,459 (23.5)                             | <0.0001 |
| Autoimmune disorders     |                        |                                          |         |
| Multiple sclerosis       | 3 (0.02)               | 9 (0.14)                                 | <0.0001 |
| Rheumatoid arthritis     | 64 (0.34)              | 101 (1.63)                               | <0.0001 |

Values are presented as n (%) or mean ± SD.

Fig. 2. Subgroup analysis by age, sex, and the presence of comorbid diseases. Odds ratios for multiple sclerosis and rheumatoid arthritis in patients with Behçet’s disease. *Not available. Odds ratios were not estimated because the number of events was too small for subgroup analyses.
In the BD group, 9 patients had multiple sclerosis and there were 3 in the control group. The increased proportion of multiple sclerosis in BD patients persisted after subgroup analyses. The OR for rheumatoid arthritis in the BD group was higher in males than in females. Patients in the BD group without comorbid diseases had a higher OR for rheumatoid arthritis than patients with comorbid disease. Patients aged <40 years (OR 23.91; 95% CI 5.50–103.9) had a higher proportion of rheumatoid arthritis than older patients (OR 3.96; 95% CI 2.83–5.54).

### Discussion

This study used a nationwide cohort database to show increased ORs for multiple sclerosis and rheumatoid arthritis in BD patients compared to controls.

The incidence of BD in Korea is reported to be 4.0 per 100,000 person-years [4]. Rates of comorbid metabolic diseases such as diabetes mellitus, hypertension, and dyslipidemia are significantly higher in patients with BD in Korea than in controls without BD [4]. Although inflammatory bowel disease as a comorbidity is suggested to be increased in patients with BD, the association of rheumatoid arthritis and multiple sclerosis with BD has not been previously reported.

Some neuro-BD patients are reported to have clinical and laboratory features resembling multiple sclerosis rather than neuro-BD [23–25]. Neuro-BD mimics multiple sclerosis in some aspects, including a high occurrence in young individuals, a relapsing-remitting or progressive course, the perivascular infiltration of inflammatory cells, hyperintense lesions on T2-weighted magnetic resonance imaging (MRI), abnormal evoked potentials, and a treatment response to corticosteroids and immunosuppressant drugs [25]. However, parenchymal involvement is typically seen in the basal ganglia and diencephalon in neuro-BD and in periventricular and white-matter lesions in multiple sclerosis. The hygiene hypothesis states that multiple sclerosis is frequently observed in developed countries. However, neuro-BD is associated with poor hygiene, with an increased chance of exposure to infectious agents [26]. Since the treatments are different for multiple sclerosis and neuro-BD, differentiating neuro-BD from multiple sclerosis is important [23]. Both neuro-BD and multiple sclerosis cause cognitive dysfunctions such as impairments in memory and frontal-lobe executive function. The pathogenic mechanisms underlying the association between BD and multiple sclerosis have not yet been established; however, several studies have investigated possible mechanisms [26, 27]. According to Oezguen et al. [27], an altered gut microbiota community is implicated in neuro-BD and multiple sclerosis.

The proportion of rheumatoid arthritis is increased in patients with BD; however, the association between rheumatoid arthritis and BD has not been fully established. A case report showed BD development in a patient with longstanding rheumatoid arthritis [28]. A vitamin D receptor gene polymorphism has been reported in both BD and rheumatoid arthritis [29, 30]. However, little is known about a possible pathomechanism between the 2 diseases.

This study has several limitations. First, the possibility of misdiagnosis cannot be ruled out. Some patients may have been clinically classified as having multiple sclerosis or rheumatoid arthritis for therapeutic purposes or to gain government support. However, the OR for multiple sclerosis and sero-positive rheumatoid arthritis in BD patients was significantly higher than in controls and high rates of overlap symptoms were worthy of notice. Second, although multiple sclerosis is diagnosed via spinal tap and MRI findings that are different from neuro-BD, we cannot identify whether the neuro-BD patients were misdiagnosed as having multiple sclerosis. It is difficult to differentiate the MRI findings of neuro-BD and multiple sclerosis. Because the KNHIS does not allow access to the chart review of patients, it was impossible to clarify whether an accurate diagnosis had been made. However, results suggest that neurologic manifestation may appear first in BD patients, and it is possible that the first neurologic symptoms of BD might mimic clinical manifestation of multiple sclerosis. Third, there was a possibility that arthritis symptoms in BD patients were misdiagnosed as rheumatoid arthritis. However, in this study,

| Autoimmune and autoinflammatory disorders | Odds ratio (95% confidence interval) |
|------------------------------------------|------------------------------------|
|                                          | Model 1    | Model 2    |
| Multiple sclerosis                       | 9 (2.44–33.24) | 8.85 (2.36–33.17) |
| Rheumatoid arthritis                    | 4.78 (3.49–6.55) | 4.62 (3.35–6.35) |

The reference was the control group. A multivariate logistic regression model of comorbid diseases was used for Model 2. Model 1: Univariate. Model 2: Multivariate with adjustment for diabetes mellitus, hypertension, and dyslipidemia and other autoimmune disorders (multiple sclerosis or rheumatoid arthritis).
rheumatoid arthritis with rheumatoid factor positivity (ICD-10 code M05 and rare intractable diseases code V223) was diagnosed by a rheumatologist according to criteria excluding sero-negative rheumatoid arthritis (ICD-10 code M06). Fourth, health-related habits such as smoking status or alcohol consumption were not available in the HIRA database. Health-related habits might influence the incidence of BD [14, 19, 31] but the HIRA database does not include this information.

Despite its limitations, this study has several strengths. It was a nation-wide, population-based cohort study. The ORs for rheumatoid arthritis and multiple sclerosis were remarkably high in patients with newly diagnosed BD. We propose that there are indeed increased ORs for these autoimmune disorders in patients with BD. Physicians should be aware of the high proportion of these autoimmune disorders in their patients with BD and treatment should also take into account common concurrent autoimmune disorders. This study will help to broaden our understanding of BD pathogenesis.

Key Message
Behçet’s disease is associated with multiple sclerosis and rheumatoid arthritis.
