Abstract

Introduction: The small and large intestine account for the majority of GI tract. They are the sites of a broad array of diseases. These include both neoplastic and non-neoplastic, such as inflammatory lesions, polyps, cancerous growths, with some of the inflammatory lesions being premalignant. Epithelial tumors are major cause of morbidity & mortality. Colorectal cancer is the fourth ranking cancer worldwide, accounting for approximately 9% of all cancers. This study was conducted to study histopathological spectrum of lesions in intestine and their age and sex distribution.

Materials and Methods: It was a retrospective study conducted in the Department of Pathology, GMERS Medical College and Civil Hospital, Sola, Ahmedabad from January 2018 to December 2018. The specimens included were endoscopic biopsies as well as resections of colon and part of intestine.

Results: Total 131 intestinal specimens were received in our hospital over the period of January 2018 to December 2018. Overall non-neoplastic lesions (87.8%) were more common than neoplastic lesions (12.2%). Most common non-neoplastic lesion in small intestine was peptic ulcer and in large intestine was fistula. In large intestine, most common neoplastic lesion was adenocarcinoma.

Conclusion: This study concludes that a variety of lesions occur in small and large intestine which have a vague presentation. Timely histopathological diagnosis and its clinical correlation help in early management and improve the survival.

Keywords: Intestinal lesions, small intestine, large intestine, neoplastic, non-neoplastic, adenocarcinoma, malignant melanoma

Introduction

The small intestine and large intestine account for the majority of GI tract.¹ They are the sites of a broad array of diseases.² These include both neoplastic and non-neoplastic, such as inflammatory lesions, polyps, cancerous growths, with some of the inflammatory lesions being premalignant. Epithelial tumors are major cause of morbidity & mortality. Colorectal cancer is the fourth ranking cancer worldwide, accounting for approximately 9% of all cancers.² Adenocarcinomas are the commonest malignancies arising in the colorectal region, other being carcinoid, anal zone carcinoma & melanoma.³ This study was conducted to study histopathological spectrum of lesions in intestine and their age and sex distribution.

Materials and Methods

Specimens from small and large intestines were included in the study. The study period was from January 2018 to December 2018. It was a retrospective study conducted in the Department of Pathology, GMERS Medical College and Civil Hospital, Sola, Ahmedabad. The specimens included were endoscopic biopsies as well as resections of colon and part of intestine. The biopsies received were fixed in 10% buffered formalin and processed in an automated processor. The paraffin embedded sections were taken and stained with Hematoxylin and Eosin. Special stains like Giemsa, Ziehl Neelson, Fite Faraco, Alcian blue and Periodic Acid Schiff stains were used as and when necessary.

Results

Total 131 intestinal specimens were received in our hospital over the period of January 2018 to December 2018. The site wise distribution is shown in Table: 1. Large intestinal lesions (71.8%) were more common than small intestinal lesions (28.2%).

As shown in Table: 2; out of total specimens 77.8% were of males and 22.2% of females.

As shown in Table: 3; non-neoplastic lesions are more common in both small and large intestines. Overall non-neoplastic lesions (87.8%) were more common than neoplastic lesions (12.2%).

Table: 4 shows histopathological distribution of non-neoplastic intestinal lesions. Most common non-neoplastic lesion in small intestine was peptic ulcer and in large intestine was fistula.

Out of neoplastic lesions, 12 were malignant and 4 were benign as shown in Table: 5.

As shown in Table: 6; in large intestine, most common neoplastic lesion was adenocarcinoma.

Table 1: Site wise distribution of intestinal specimens

| Site of lesion | No. of biopsies |
|----------------|-----------------|
| Small intestine | 37(28.2%) |
| Large intestine | 94(71.8%) |

Table 2: Sex wise distribution of intestinal specimens

| Sex   | Number |
|-------|--------|
| Male  | 102(77.8%) |
| Female| 29(22.2%) |

Table 3: Distribution of specimens according to nature of lesion

| Site         | Non neoplastic | Neoplastic |
|--------------|----------------|------------|
| Small intestine | 36             | 1          |
| Large intestine | 79             | 15         |
| Total         | 115(87.8%)     | 16(12.2%)  |
Table 4: Distribution of non neoplastic intestinal lesions according to histopathology

| Site            | Lesion                                      | number |
|-----------------|---------------------------------------------|--------|
| Small Intestine | Peptic ulcer                                | 11     |
|                 | Acute infarction                            | 4      |
|                 | Acute necrotizing inflammation              | 4      |

Discussion
A total of 131 cases of intestinal lesions were studied over a period of one year from January 2018 to December 2018. Among them, there were 115 cases of non neoplastic lesions and 16 cases of neoplastic lesions. Amongst the non neoplastic lesions, most common lesion was fistula accounting for 40%.
Of 16 cases of neoplastic lesions, 12 cases were of malignant neoplasms on histopathological examination, 4 cases of benign neoplasms. It was observed that, out of 142 malignant lesions of all sites in the body, 12 cases were of intestinal malignancies, thus constituting 8.45% of all malignant lesions during the study period.

Lesions of Small Intestine
Most common lesion diagnosed was peptic ulcer. There were 3 cases of tuberculosis all involving terminal ileum. In one, perforation was present. Tuberculous granulomas are caseating in nature and have peripheral infiltration containing lymphocytes, plasma cells and Langhans type of giant cells. Acid fast bacilli were demonstrated on Ziehl–Neelsen stain. Fig. 1 (a) and (b) show tuberculous granuloma in H & E stain and Acid fast bacilli in ZN stain. Squamous cell carcinoma was detected in resected intestine with metastasis in mesenteric lymph node. Mucosa was free from tumor. Later on it was found to be metastatic from other site. Fig. 2 (a), (b) and (c) show histomorphology of SCC on low power and high power view and metastatic foci in lymph node.

Lesions of Large Intestine
Most common diagnosis given was fistula followed by hemorrhoids. Tuberculosis was diagnosed in 1 case. 2 cases of amoebic colitis were recorded. Confirmation was done by demonstration of trophozoites of Entamoeba histolytica by Periodic acid-Schiff (PAS) staining. As seen Fig. 3, trophozoites are round to ovoid with abundant cytoplasm and small round nuclei.

Total 11 malignant cases were reported. Out of them, 9 were of Adenocarcinoma, 1 of squamous cell carcinoma and 1 of malignant melanoma. Table: 7 shows comparison of distribution of histologic types of adenocarcinoma with study done by Ritesh et al. The results were in discordance with Ritesh et al. In our study most common type was well differentiated adenocarcinoma while in study done by Ritesh et al. most common was moderately differentiated one.

One case of mucinous carcinoma was reported. Fig. 4 (a),(b) and (c) show gross and microscopic features of mucinous adenocarcinoma of colon. Mucinous carcinoma presents as grayish white solid cystic exophytic mass reaching upto serosa. Cystic spaces were filled with mucin lakes. Microscopically mucinous foci constitute atleast 50% of tumor mass with malignant cells forming glands.

One case of malignant melanoma was reported. Figure: V shows gross and microscopic features of malignant melanoma. It was received as a resected polypoid mass. Cut surface was brownish black. Microscopically it showed malignant epithelioid cells with some binucleated and multinucleated bizarre tumor giant cells. The epithelioid cells contain abundant melanin pigment in cytoplasm.

Thus histopathological examination was useful in reaching the final diagnoses including rare lesions like mucinous adenocarcinoma, malignant melanoma, etc. Special stains were useful in identifying causative organisms. Examples are: Ziehl Neelson stain for M. tuberculosis and Periodic Acid-Schiff stain for E. Histolytica.

Conclusion
This study concludes that a variety of lesions occur in small and large intestine which have a vague presentation. It makes their diagnosis difficult. Timely histopathological diagnosis and its clinical correlation help in early management and improve the survival.

Conflict of Interest: None.
