Pilomatricoma—unveiling the ghost story: A case series

Ranjan Agrawal, Parbodh Kumar

ABSTRACT

Introduction: Pilomatrixoma are benign skin neoplasms of hair follicle origin but often are mis-diagnosed. They present as superficial masses of the head and neck especially in children. This present study is aimed at pointing to awareness among the clinicians as well as the pathologists about the varied presentations and morphological features of the entity.

Case Series: Five cases were included in the present study, of which four were females and one male. The sites involved were right thigh, right elbow, forehead, right eyebrow and subareolar area in the right breast.

Conclusion: Diagnostic pitfalls have been discussed along with the clinical differential diagnosis.
**ABSTRACT**

Introduction: Pilomatricoma are benign skin neoplasms of hair follicle origin but often are mis-diagnosed. They present as superficial masses of the head and neck especially in children. This present study is aimed at pointing to awareness among the clinicians as well as the pathologists about the varied presentations and morphological features of the entity. Case Series: Five cases were included in the present study, of which four were females and one male. The sites involved were right thigh, right elbow, forehead, right eyebrow and subareolar area in the right breast. Conclusion: Diagnostic pitfalls have been discussed along with the clinical differential diagnosis.

Keywords: Basaloid cells, Calcifying epithelioma of malherbe, Ghost cells, Pilomatricoma

**INTRODUCTION**

Pilomatricoma is a relatively uncommon benign skin neoplasm arising from the hair follicles. With more morphologic features and clinical presentations being described there has been a better identification of this neoplasm. Probably due to lack of awareness or otherwise a preoperative diagnosis of pilomatricoma is rarely considered by the clinicians [1].

**CASE SERIES**

Five cases were included in the present study. Four (80%) of these were females and one (20%) male. The site of involvement in all the patients were different (Table 1). Two cases (40%) occurred in the head and neck region with face as the predominant site involved. The other sites involved were lateral aspect of right thigh, right elbow and beneath the areola of the right breast. All the patients presented with a painless swelling. On examination the swellings were non-tender and freely mobile.

The clinical diagnosis in all the cases was suggestive of epidermoid/dermoid cyst. However, subsequent histopathologic examination confirmed these cases as pilomatricoma. All the lesions were well encapsulated. H&E sections showed dual population of cells comprising the peripheral basaloid cells and the ghost or shadow cells in the centre (Figure 1). A transition of basaloid to ghost cells was noted in many areas. Sections from the right eyebrow swelling posed great difficulty in diagnosis since there were mainly ghost cells present and almost negligible basophilic cells representing stage 4 (Figure 2). The remaining four cases (80%) belonged to the third morphological stage. Two cases showed a rich infiltrate of lymphoplasmacytic cells and numerous foreign body giant cells near the shadow cells (Figure 3). Three cases showed areas of calcification.
Pilomatrixoma, or calcifying epithelioma of Malherbe, was first described in 1880 by Malherbe and Chenantais as a benign subcutaneous tumor arising from the sebaceous glands. In 1922, Dubreuilh and Cazenave described the unique histopathologic characteristics of this neoplasm, including islands of epithelial cells and shadow cells. Turhan and Krainer in 1942 stated the origin of this neoplasm to be from the hair cortex cells. In 1961, Forbis and Helwig proposed the term pilomatrixoma denoting their origin from cells of hair matrix and avoiding overlapping nomenclature with malignancy as suggested by the previously used term “Epithelioma”. In 1977, the name was corrected etymologically to pilomatricoma.

The incidence of pilomatricoma is estimated to be 1 in 2000 surgical specimens [2]. The most frequent anatomical location is the head and neck region, followed by the upper extremities, trunk and the lower extremities in decreasing order of frequency [1]. The sites of occurrence reported in the head and neck region are cheek (36%), neck (20%), periorbital region (14%), scalp (9%) and remaining as multiple lesions [1–8]. Involvement of palms, soles, genital region or lymph nodes has not been reported [1]. Reports of involvement of breasts are also

| Case | Age | Sex | Site involved          | Presentation      | Duration    | Morphological Stage |
|------|-----|-----|------------------------|-------------------|-------------|---------------------|
| 1    | 30  | F   | Lateral aspect of right thigh | Painless swelling | 1 year      | 3                   |
| 2    | 11  | F   | Right elbow            | Painless swelling | 18 Months   | 4                   |
| 3    | 37  | M   | Forehead                | Painless swelling | 9 Months    | 3                   |
| 4    | 33  | F   | Right eyebrow          | Painless swelling | 8 Months    | 3                   |
| 5    | 16  | F   | Subareola right breast  | Painless Nodule   | 13 Months   | 3                   |

**DISCUSSION**

Pilomatrixoma, or calcifying epithelioma of Malherbe, was first described in 1880 by Malherbe and Chenantais as...
available [9]. A rare case of pilomatricoma following split thickness skin graft on the lower extremity is available in literature [10]. The female to male ratio reported is 1.5:1 [1, 7]. Female predominance was observed in the present study as well. Pilomatricoma can develop at any age, demonstrating bimodal peak presentation during the first and sixth decades of life. About 40% of cases occur in patients younger than 10 years of age and about 60% of cases within the first two decades of life [1]. In the present study, all five patients were below 40 years of age with 2 between 20 years.

Pilomatricoma mainly presents as a solitary cutaneous nodule with an average size of 1 cm rarely exceeding 2 cm in diameter and is covered by normal or hyperemia skin [11, 12]. All the cases in the present study had similar presentation. Four cases measured less than 1 cm and one was 1.5 cm in diameter. They are usually asymptomatic, deep seated, firm, non-tender and adherent to the skin but not fixed to the underlying tissue. Multiple occurrences and familial cases are also known, in association with disorders like Gardner’s syndrome, Steinert disease, Sarcoidosis, Rubinstein-Taybi syndrome, Turner syndrome and Myotonic dystrophy [1, 7, 13]. No such association was observed in any of our cases. Stretching of the skin over the tumor shows the “tent sign” with multiple facets and angles, a pathognomonic sign for pilomatricoma [1, 14]. In addition, pressing on one edge of the lesion causes the opposite edge to protrude from the skin like a “teeter-totter”. Another characteristic feature is the blue-red discoloration of the overlying skin differentiating it from epidermal inclusion or dermoid cysts [1].

The accuracy rate of preoperative diagnosis of pilomatricoma reported ranges from 0–30% probably due to the lack of familiarity with this tumor [15]. Radiologic imaging is of little diagnostic value for pilomatricoma. Fine-needle aspiration cytology has a limited role since the results can be misleading if there are no ghost cells present in the aspirate [1]. The major factors contributing to misdiagnosis include cystic lesions with varying consistency, punctum like appearance (due to skin tethering), atypical location and a lack of familiarity with this tumor [15]. Radiologic imaging is of little diagnostic value for pilomatricoma. Fine-needle aspiration cytology has a limited role since the results can be misleading if there are no ghost cells present in the aspirate [1].

Since there is no spontaneous regression, malignant transformation to pilomatrical carcinoma is very rare. Pilomatrix carcinoma needs to be distinguished from proliferating pilomatricoma, which is a benign tumor exhibiting a relative symmetry, sharp circumscription and a distinct lobular proliferation of basaloid cells with most of them exhibiting prominent nucleoli. The ghost cells show well-defined cell borders abundant, pale, eosinophilic cytoplasm with a central clear area. A transition of basaloid cells to ghost cells is noted in many areas. There can be areas of keratinization, calcification, ossification, melanin deposition and focal lymphocytic infiltration along with a foreign body giant cell reaction in close proximity to the ghost cells. Secondary changes such as hemorrhage, ossification, myxoid change, edema and stromal fibrosis may occur [2].

Four distinct morphological stages of pilomatricoma reported include: (a) Early: small and cystic lesions, (b) Fully developed: large and cystic, (c) Early regressive: foci of basaloid cells, shadow cells and lymphocytic infiltrate with multinucleated giant cells, (d) Late regressive: numerous shadow cells with absence of basaloid and inflammatory cells. These stages reflect the evolution of the tumor from a matrix cyst to a calcified and ossified nodule with no visible epithelial component [1, 15]. They do not have treatment or prognostic implication.

Complications of pilomatricoma are rare. However, occasionally they may grow to several centimeters in diameter. Transformation to pilomatrical carcinoma is very rare. Pilomatrix carcinoma needs to be distinguished from proliferating pilomatricoma, which is a benign tumor exhibiting a relative symmetry, sharp circumscription and a distinct lobular proliferation of basaloid cells with small foci of shadow cells along with variable nuclear atypia and mitosis [2, 18].

Since there is no spontaneous regression, malignant transformation is rare and the lesions are well encapsulated, the standard treatment of pilomatricoma is complete surgical excision [1, 6].

**CONCLUSION**

This study illustrates the diagnostic pitfalls of pilomatricoma with special emphasis on its presentations and differentials. The diagnostic pitfalls have been
highlighted in the present study. We would reiterate the significance of the knowledge of these cases and also to make the clinicians aware of this entity especially as a cause of solitary skin nodule on the head, neck, breast or the upper extremities.

Edorium Journals: An introduction

Edorium Journals Team

About Edorium Journals
Edorium Journals is a publisher of high-quality, open access, international scholarly journals covering subjects in basic sciences and clinical specialties and subspecialties.

Invitation for article submission
We sincerely invite you to submit your valuable research for publication to Edorium Journals.

But why should you publish with Edorium Journals?
In less than 10 words - we give you what no one does.

Vision of being the best
We have the vision of making our journals the best and the most authoritative journals in their respective specialties. We are working towards this goal every day of every week of every month of every year.

Exceptional services
We care for you, your work and your time. Our efficient, personalized and courteous services are a testimony to this.

Editorial Review
All manuscripts submitted to Edorium Journals undergo pre-processing review, first editorial review, peer review, second editorial review and finally third editorial review.

Peer Review
All manuscripts submitted to Edorium Journals undergo anonymous, double-blind, external peer review.

Early View version
Early View version of your manuscript will be published in the journal within 72 hours of final acceptance.

Manuscript status
From submission to publication of your article you will get regular updates (minimum six times) about status of your manuscripts directly in your email.

Our Commitment

Six weeks
You will get first decision on your manuscript within six weeks (42 days) of submission. If we fail to honor this by even one day, we will publish your manuscript free of charge.

Four weeks
After we receive page proofs, your manuscript will be published in the journal within four weeks (31 days). If we fail to honor this by even one day, we will publish your manuscript free of charge and refund you the full article publication charges you paid for your manuscript.

Mentored Review Articles (MRA)
Our academic program “Mentored Review Article” (MRA) gives you a unique opportunity to publish papers under mentorship of international faculty. These articles are published free of charges.

Favored Author program
One email is all it takes to become our favored author. You will not only get fee waivers but also get information and insights about scholarly publishing.

Institutional Membership program
Join our Institutional Memberships program and help scholars from your institute make their research accessible to all and save thousands of dollars in fees make their research accessible to all.

Our presence
We have some of the best designed publication formats. Our websites are very user friendly and enable you to do your work very easily with no hassle.

Something more...
We request you to have a look at our website to know more about us and our services.

We welcome you to interact with us, share with us, join us and of course publish with us.
