Abstract—In underlay heterogeneous networks (HetNets), the distance between a macro base station (MBS) and a macro user (MU) is crucial for a small-cell based station (SBS) to control the interference to the MU and achieve the coexistence. To obtain the distance between the MBS and the MU, the SBS needs a backhaul link from the macro system, such that the macro system is able to transmit the information of the distance to the SBS through the backhaul link. However, there may not exist any backhaul link from the macro system to the SBS in practical situations. Thus, it is challenging for the SBS to obtain the distance. To deal with this issue, we propose a median based (MB) estimator for the SBS to obtain the distance between the MBS and the MU without any backhaul link. Numerical results show that the estimation error of the MB estimator can be as small as 4%.

I. INTRODUCTION

The heterogeneous network (HetNet) is a promising candidate to provide flexible wireless accesses for future wireless communications [1]. Within a HetNet, a macro base station (MBS) is expected to provide wide coverage of users in the macro cell. Meanwhile, a small-cell base station (SBS) in the macro cell coexists with the MBS and is responsible for providing high data rate services for the users in the small cell. An effective way to achieve the coexistence between the small cell and the macro cell is underlay HetNet [2], [3]. In the underlay HetNet, the SBS is allowed to access the macro frequency band to enhance the small-cell throughput, provided that the interference from the SBS to a macro user (MU) is well controlled.

To implement an underlay HetNet, the location information of the MU is important for the SBS to control its transmit power and manage the interference to the MU. Intuitively, if the MU is out of the SBS’s coverage, the SBS is allowed to maximize the transmit power and achieve a high small-cell throughput. Otherwise, if the MU is in the SBS’s coverage, the SBS has to carefully control the transmit power to avoid severe interference to the MU. To obtain the location information of the MU, the SBS needs a backhaul link from the macro system, such that the macro system is able to transmit the location information of the MU to the SBS through the backhaul link [4], [5], [6]. However, there may not exist any backhaul link from the macro system to the SBS in practical situations. Thus, it is challenging for the SBS to obtain the location information of the MU for the underlay HetNet.

Recently, the underlay HetNet has been extensively studied [7], [8], [9]. Instead of utilizing the instantaneous location information of the MU to manage the interference, these literature exploited the stochastic geometry information of the MU and enabled the SBS to satisfy an average interference constraint. In particular, the Poisson point process (PPP) model is widely adopted to enhance the access probability of the SBS, while guaranteeing a small outage probability of the MU. However, this approach can only provide limited access probability of the SBS and compromises the small-cell throughput.

To deal with this issue, we intend to estimate the distance between the MBS and the MU, such that the SBS can exploit the distance to achieve the underlay HetNet. Briefly, if the distance is too small or too large compared with the distance between the MBS and the SBS, the SBS’s transmission will not interfere with the MU since the MU is almost surely beyond the SBS’s coverage in this case. If the distance between the MBS and the MU is comparable with the distance between the MBS and the SBS, the SBS has to control its transmit power to avoid severe interference to the MU since it is likely that the MU is in the SBS’s coverage.

In fact, it is possible for the SBS to obtain the distance between the MBS and the MU without any backhaul link from the macro system. In principle, if the MBS is transmitting data to the MU with a target SNR, the transmitted signal is designed based on the distance between the MBS and the MU. In particular, if the distance is small, the MBS is able to satisfy the target SNR with a small transmit power. Otherwise, the MBS increases its transmit power to achieve the target SNR. In other words, the transmitted signal from the MBS contains some information of the distance between the MBS and the MU. Thus, the SBS can estimate the distance by sensing the transmitted signal from the MBS.

In this paper, we first study the relation between the MBS signal and the distance from the MBS to the MU. With this relation, we enable the SBS to sense the MBS signal and develop a median based (MB) estimator to obtain the distance. Numerical results show that the estimation error of the MB estimator can be as small as 4%.

II. SYSTEM MODEL

Fig. 1 provides a HetNet model, which consists of a MBS, a MU, and a SBS. In particular, the MBS is transmitting data to the MU. Meanwhile, the SBS intends to estimate the distance \( d_0 \) between the MBS and the MU to achieve the underlay HetNet. In what follows, we present the channel model and the signal model, respectively.

A. Channel Model

We denote \( h_0 \) \((h_1)\), \( g_{s0} \) \((g_{s1})\), and \( g_0 \) \((g_1)\) as the fading, the shadowing, and the path-loss coefficients between the MBS and the MU (SBS), respectively. Then, the channel between the MBS and the MU (SBS) is \( h_0 \sqrt{g_{s0}} g_0 \) \((h_1 \sqrt{g_{s1}} g_1)\). In particular, \( |h_1| \) \((q = 0, 1)\) follows a Rayleigh distribution with unit mean. \( g_{s0} \) \((q = 0, 1)\) follows a log-normal distribution with variance \( \sigma_{s0}^2 \). \( g_0 \) \((q = 0, 1)\) is determined by the path-loss model. If we adopt the path-loss model [10]

\[
P_d(d_q) = 128 + 37.6 \log_{10}(d_q), \quad \text{for} \quad d_q \geq 0.035 \text{ km},
\]

where \( d_q \) is the distance between two transceivers, \( g_q \) can be expressed as

\[
g_q = 10^{-12.8} d_q^{-3.76}, \quad \text{for} \quad d_q \geq 0.035 \text{ km}.
\]

For illustrations, we provide the channel model in Fig. 2 where time axis is divided into blocks and each block consists of multiple subblocks. In particular, \( g_q \) remains constant all the time with a given \( d_q \), \( g_{s0} \) \((q = 0, 1)\) remains constant within each block \(i\) and varies independently among different blocks, and \( h_q \) \((q = 0, 1)\) remains constant within each subblock \(i, j\) and varies among different subblocks.

B. Signal Model

1) Signal model from the MBS to the MU: Denote \( x_m \) as the MBS signal with unit power, i.e., \( |x_m|^2 = 1 \). If the MBS transmits the signal with power \( p_0 \), the received signal at the MU is

\[
y_0(i,j) = h_0(i,j) \sqrt{g_{s0}(i)p_0(i,j)}x_0(i,j) + n_0(i,j),
\]

where \((i)\) denotes the index of the \(i\)th block, \((i,j)\) represents the index of the \(j\)th subblock in the \(i\)th block, \(n_0\) represents the AWGN at the MU with zero mean and variance \( \sigma^2 \). Then, the SNR of the received signal at the MU is

\[
\gamma_0(i,j) = \frac{|h_0(i,j)|^2 g_{s0}(i)p_0(i,j)}{\sigma^2}.
\]

We further consider that the MBS and the MU adopt close loop power control (CLPC) to provide QoS guaranteed wireless communication [11]. That is, the MBS automatically adjusts its transmit power to meet a certain target SNR \( \gamma_T \) at the MU. Then, MBS’s transmit power is

\[
p_0(i,j) = \frac{\gamma_T \sigma^2}{|h_0(i,j)|^2 g_{s0}(i)}. \quad (5)
\]

2) Signal model from the MBS to the SBS: In the meantime, the received MBS signal at the SBS is

\[
y_1(i,j) = h_1(i,j) \sqrt{g_{s1}(i)p_0(i,j)}x_0(i,j) + n_1(i,j), \quad (6)
\]

where \( n_1 \) is the AWGN at the SBS with zero mean and variance \( \sigma^2 \). Then, the SNR of the received MBS signal at the SBS is

\[
\gamma_1(i,j) = \frac{|h_1(i,j)|^2 g_{s1}(i)p_0(i,j)}{\sigma^2}. \quad (7)
\]

By Substituting (2) and (5) into (7), \( \gamma_1(i,j) \) in (7) can be rewritten as

\[
\gamma_1(i,j) = \frac{\gamma_T d_0^{-3.76} g_{s1}(i)|h_1(i,j)|^2}{d_0^{-3.76} g_{s0}(i)|h_0(i,j)|^2}. \quad (8)
\]

III. MEDIAN BASED (MB) ESTIMATOR

In this section, we will develop a MB estimator to obtain the distance \( d_0 \) between the MBS and the MU. In what follows, we provide the basic principle of the estimator followed by the estimator design.

A. Basic Principle

From (8), each SNR of the received MBS signal at the SBS is highly related to the distance \( d_0 \). Then, it is possible for
the SBS to measure the SNR of the received MBS signal and estimate $d_0$. However, it is difficult to obtain $d_0$ directly. This is because, each SNR is also affected by random Rayleigh fading and shadowing attenuations, and varies independently among different blocks and/or subblocks. Alternatively, the SBS can measure different SNRs of MBS signals in multiple blocks and utilize the distribution knowledge of the Rayleigh fading and shadowing attenuations to estimate $d_0$.

Next, we will first calculate the cumulative density function (CDF) of the SNR at the SBS. Then, we study the relation between the CDF of the SNR at the SBS and the distance $d_0$. Finally, we develop the MB estimator.

B. CDF of the SNR at the SBS

Removing the time index of the SNR at the SBS in (8) and rewriting the SNR in dB, we have

$$\gamma_{1,dB} = \gamma_{T,dB} + 37.6\log_{10}\frac{d_0}{d_1} + \Theta_r + \Theta_s,$$

where $\Theta_r = 10\log_{10}\left(\frac{h_r^2}{h_0^2}\right)$ and $\Theta_s = 10\log_{10}(g_s) - 10\log_{10}(g_{so})$. Next, we first calculate the probability density function (PDF) of $\Theta_r$ and $\Theta_s$, and then obtain the CDF of $\gamma_{1,dB}$.

On one hand, both $|h_0|$ and $|h_1|$ follow a Rayleigh distribution with unit mean, the CDF of $\phi = |h_1|^2/|h_0|^2$ is [12]

$$F_\phi(\phi) = \frac{\phi}{\phi + 1}. \quad (9)$$

Then, the CDF of $\Theta_r = 10\log_{10}(\phi)$ is

$$F_{\Theta_r}(\theta_r) = \Pr\{10\log_{10}(\phi) \leq \theta_r\} = \Pr\left\{\phi \leq 10^{\frac{\theta_r}{10}}\right\} = F_\phi\left(10^{\frac{\theta_r}{10}}\right). \quad (10)$$

Substituting (9) into (10), we have the CDF of $\Theta_r$ as

$$F_{\Theta_r}(\theta_r) = \frac{1}{1 + 10^{-\frac{\theta_r}{10}}} \quad (11)$$

Taking the derivation of $F_{\Theta_r}(\theta_r)$, we have the PDF of $\Theta_r$ as

$$f_{\Theta_r}(\theta_r) = \frac{\ln 10 \cdot 10^{-\frac{\theta_r}{10}}}{10\left(1 + 10^{-\frac{\theta_r}{10}}\right)^2}. \quad (12)$$

On the other hand, both $g_{so}$ and $g_s$ follow a log-normal distribution with variance $\sigma_s^2$. Then, it is straightforward to obtain that $\Theta_s$ follows a normal distribution with zero means and variance $2\sigma_s^2$. Thus, the PDF of $\Theta_s$ is

$$f_{\Theta_s}(\theta_s) = \frac{1}{\sqrt{4\pi\sigma_s^2}} e^{-\frac{\theta_s^2}{4\sigma_s^2}}. \quad (13)$$

Note that, the CDF of $\gamma_{1,dB}$ is

$$F_{\gamma_{1,dB}}(\gamma_{1,dB}) = \Pr\left\{\gamma_{T,dB} + 37.6\log_{10}\frac{d_0}{d_1} + \Theta_r + \Theta_s \leq \gamma_{1,dB}\right\} = \Pr\left\{\Theta_r + \Theta_s \leq \gamma_{1,dB} - \gamma_{T,dB} - 37.6\log_{10}\frac{d_0}{d_1}\right\}. \quad (14)$$

If we denote $m(\gamma_{1,dB}) = \gamma_{1,dB} - \gamma_{T,dB} - 37.6\log_{10}\frac{d_0}{d_1}$, the CDF of $\gamma_{1,dB}$ in (14) can be calculated as

$$F_{\gamma_{1,dB}}(\gamma_{1,dB}) = \Pr\{\Theta_r + \Theta_s \leq m(\gamma_{1,dB})\} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f_{\Theta_s}(\theta_s) f_{\Theta_r}(\theta_r) d\theta_r d\theta_s = \int_{-\infty}^{\infty} f_{\Theta_s}(\theta_s) \Phi\left(m(\gamma_{1,dB}) - \theta_s\right) d\theta_s. \quad (15)$$

C. Relations between the CDF of $\gamma_{1,dB}$ and the Distance $d_0$

To begin with, we provide the definition of the median $x_{\frac{1}{2}}$ of a random variable $X$ as follows,

**Definition 1**: For a random variable $X$ with CDF $F_X(x)$, $x \in \mathbb{R}$, if $x_{\frac{1}{2}}$ satisfies both $F_X(x_{\frac{1}{2}}) = \Pr\{X \leq x_{\frac{1}{2}}\} = \frac{1}{2}$ and $1 - F_X(x_{\frac{1}{2}}) = \Pr\{X \geq x_{\frac{1}{2}}\} = \frac{1}{2}$, $x_{\frac{1}{2}}$ is defined as the median of the random variable $X$.

Based on Definition 1, we can obtain the median $\gamma_{1,dB,\frac{1}{2}}$ of the random variable $\gamma_{1,dB}$ by letting $F_{\gamma_{1,dB}}(\gamma_{1,dB})$ in (15) be $\frac{1}{2}$, i.e.,

$$\int_{-\infty}^{\infty} f_{\Theta_s}(\theta_s) \Phi\left(m(\gamma_{1,dB,\frac{1}{2}}) - \theta_s\right) d\theta_s = \frac{1}{2}. \quad (16)$$

Then, we have the following Theorem.

**Theorem 1**: The median $\gamma_{1,dB,\frac{1}{2}}$ enables $m(\gamma_{1,dB,\frac{1}{2}}) = 0$ to hold.

**Proof**: The detailed proof of this Theorem is provided in the Appendix.

Theorem 1 indicates that the relation between the median $\gamma_{1,dB,\frac{1}{2}}$ and the distance $d_0$ satisfies

$$m(\gamma_{1,dB,\frac{1}{2}}) = \gamma_{1,dB,\frac{1}{2}} - \gamma_{T,dB} - 37.6\log_{10}\frac{d_0}{d_1} = 0. \quad (17)$$

Thus, if $\gamma_{1,dB,\frac{1}{2}}$ is available at the SBS, $d_0$ can be directly calculated with (17). However, $\gamma_{1,dB,\frac{1}{2}}$ is unknown to the SBS in practical situations. To deal with this issue, we will first estimate $\gamma_{1,dB,\frac{1}{2}}$ and then obtain the estimation of $d_0$ with (17).

D. Estimator Design

We first give the definition of the sample median $x_{\frac{1}{2}}$ of a random variable $X$ as follows,

**Definition 2**: For a random variable $X$ with samples $x_m$ $(1 \leq m \leq M)$, if $x_{\frac{1}{2}}$ satisfies both $\Pr\{x_m \leq x_{\frac{1}{2}}\} = \frac{1}{2}$ and $\Pr\{x_m \geq x_{\frac{1}{2}}\} = \frac{1}{2}$, $x_{\frac{1}{2}}$ is defined as the sample median of the random variable $X$.

If the SBS observes MBS signals in $I$ blocks and measures $\gamma_{1,dB}$ of $J$ subblocks within each block, the SBS is able to
measure $K = IJ$ independent samples of $\gamma_{1,dB}$, namely, $\gamma_{1,dB}(i, j)$ $(1 \leq i \leq I, 1 \leq j \leq J)$. In what follows, we will approximate the median $\gamma_{1,dB}^{\dagger}$ with the sample median $\gamma_{1,dB}^{\dagger}$ of these $K$ samples. Then, by substituting the approximated $\gamma_{1,dB}^{\dagger}$ into (17), we obtain the estimation of $d_0$.

To begin with, by sorting the $K$ samples in ascending order, the $K$ samples can be relabelled as $\tilde{\gamma}_{1,dB}(k)$ $(1 \leq k \leq K)$, i.e., $\tilde{\gamma}_{1,dB}(k_1) \leq \tilde{\gamma}_{1,dB}(k_2)$ for $1 \leq k_1 \leq k_2 \leq K$. Since the sample medians $\gamma_{1,dB}^{\dagger}$ of these $K$ samples for odd and even $K$ can be different, we will develop the MB estimator for odd and even $K$ separately.

1) For the case that $K$ is odd: When $K$ is odd, the sample median is $\gamma_{1,dB}^{\dagger} = \tilde{\gamma}_{1,dB}\left(\frac{K+1}{2}\right)$. Then, the median of $\gamma_{1,dB}$ can be approximated as

$$\gamma_{1,dB}^{\dagger} \approx \tilde{\gamma}_{1,dB}\left(\frac{K+1}{2}\right). \quad (18)$$

By substituting (18) into (17), we have the MB estimator as

$$\hat{d}_0 = d_1 10^{\gamma_{1,dB}(\frac{K+1}{2}) - \gamma_{T,dB}}. \quad (19)$$

2) For the case that $K$ is even: When $K$ is even, the sample median is between $\tilde{\gamma}_{1,dB}\left(\frac{K}{2}\right)$ and $\tilde{\gamma}_{1,dB}\left(\frac{K}{2} + 1\right)$. Then, the median of $\gamma_{1,dB}$ can be approximated as

$$\gamma_{1,dB}^{\dagger} \approx \frac{\tilde{\gamma}_{1,dB}\left(\frac{K}{2}\right) + \tilde{\gamma}_{1,dB}\left(\frac{K}{2} + 1\right)}{2}. \quad (20)$$

By substituting (20) into (17), we have the MB estimator as

$$\hat{d}_0 = d_1 10^{\gamma_{1,dB}\left(\frac{K}{2}\right) + \gamma_{1,dB}\left(\frac{K}{2} + 1\right) - \gamma_{T,dB}}. \quad (21)$$

Consequently, the MB estimator can be summarized as

$$\hat{d}_0 = \begin{cases} d_1 10^{\frac{\gamma_{1,dB}(K+1)}{\sigma_{dB}} - \gamma_{T,dB}} & \text{for } K \text{ is odd}, \\ d_1 10^{\frac{\gamma_{1,dB}(\frac{K}{2}) + \gamma_{1,dB}(\frac{K}{2} + 1)}{\sigma_{dB}} - \gamma_{T,dB}} & \text{for } K \text{ is even}. \end{cases} \quad (22)$$

From (22), the MB estimator $\hat{d}_0$ is determined by the target SNR $\gamma_{T,dB}$ at the MU, the distance $d_1$ between the MBS and the SBS, and the SNR $\gamma_{1,dB}$ of the MBS signal at the SBS. Note that, $\gamma_{T,dB}$ can be obtained by the SBS through observing the modulation and coding scheme (MCS) of the MBS signal [13]. $d_1$ is available at the SBS. $\gamma_{1,dB}$ is measured at the SBS and also known to the SBS. Therefore, the estimation of $d_0$ can be directly calculated with (22). In other words, the computational complexity of the MB estimator in (22) is $O(1)$.

### E. Estimation Performance Analysis

In this part, we present the estimation performance analysis of the MB estimator in Theorem 1.

**Theorem 2:** With the MB estimator in (22), $g_0$ can be bounded by

$$d_1 10^{\frac{\gamma_{c,dB}(\frac{IJ+1}{2}) - \gamma_{T,dB}}{\sigma_{dB}}} \leq d_0 \leq d_1 10^{\frac{\gamma_{c,dB}(\frac{IJ+1}{2}) - \gamma_{T,dB}}{\sigma_{dB}}} + 1 \quad (23)$$

with probability $\left(1 - \left(\frac{1}{2}\right)^{IJ+1}\right)^2$, where $[x]$ denotes the smallest integer that is no smaller than $x$, $\lceil x \rceil$ denotes the largest integer that is no larger than $x$, and $\lfloor x \rfloor$ rounds $x$ to the nearest integer.

Theorem 2 indicates that $d_0$ can be upper bounded and lower bounded by functions of the measured SNRs at the SBS with a certain probability. In particular, the probability is a function of the number of the sensed primary signals, i.e., $IJ$. For instance, we consider $I = 12$ and $J = 1$, the bounds of $d_0$ in (23) holds with probability larger than 98%. As $IJ$ increases, $d_0$ can be almost surely bounded with (23).

In Fig. 3 we illustrate estimation accuracy of the MB estimator versus the number of blocks, i.e., $I$. In particular, we set $J = 1$.

![Figure 3. Estimation accuracy of the MB estimator versus the number of blocks](image)

**IV. Numerical Results**

In this section, we provide the numerical results to demonstrate the performance of the proposed MB estimator. Here, we adopt the system model as in Section II, where the radius of the MBS’s coverage is $R = 0.5$ km, the power of the AWGN $\sigma^2 = -114$ dBm, the target SNR of the MU is $\gamma_T = 10$ dB. Furthermore, $10^4$ Monte Carlo trails are conducted for each
Figure 4. The estimation error with different $I$ and/or $J$. In particular, we set $d_0 = 0.25$ km and $d_1 = 0.1$ km.

Figure 5. The average measured SNR at the SBS when the MU and/or the SBS are in different locations, i.e., different $d_0$ and/or $d_1$. In particular, we set $I = 200$ and $J = 20$.

Figure 6. The estimation error when the MU and/or the SBS are in different locations, i.e., different $d_0$ and/or $d_1$. In particular, we set $I = 20$ and $J = 20$.

grows or $d_1$ decreases. On one hand, for a given target SNR of the received signals at the MU, a larger $d_0$ requires a larger transmit power at the MBS to satisfy the target SNR. This leads to a stronger received signal at the SBS and outputs a larger SNR. On the other hand, a smaller $d_1$ also enables the SBS to receive a stronger signal from the MBS and contributes to a larger SNR at the SBS.

Fig. 6 provides the estimation error when the MU and/or the SBS are in different locations, i.e., different $d_0$ and/or $d_1$. From this figure, the estimation error decreases as $d_0$ increases or $d_1$ decreases. Note that, both the increase of $d_0$ and the decrease of $d_1$ enhances the average SNR at the SBS from the results in Fig. 5. This reduces the measure error of each SNR at the SBS. By adopting these SNRs to estimate the distance $d_0$, the estimation error is also reduced. Besides, we observe that the estimation error converges to around 4% as $d_0$ increases or $d_1$ decreases. In addition, by comparing Fig. 5 and Fig. 6, we have the estimation error of $d_0$ with different average SNRs at the SBS as in Table I. In fact, the estimation error in Table I can be further reduced by increasing $I$ and $J$ from the results in Fig. 4. Therefore, we can select a proper $I$ and $J$ to obtain an acceptable estimation performance in practical situations.

Table I

| Average $\gamma_1 dB$ | 0 | 5 | 10 | 15 | 20 | \cdots |
|----------------------|---|---|----|----|----|--------|
| $\epsilon$           | 16% | 8% | 5% | 4.5% | 4% | 4% |

V. CONCLUSIONS

In this paper, we studied the coexistence problem between a macro cell and a small cell in an underlay HetNet. In particular, we proposed a MB estimator for the SBS to estimate the distance between the MBS and the MU. Different from the conventional approach, the MB estimator does not require any backhaul link from the macro system to the SBS. With the distance information, the SBS is able to manage the
Then, we have

\[ f(x) = \frac{1}{x} \quad \text{for} \quad x > 1 \]

Here, we complete the proof of Theorem 1.

VI. APPENDIX

To prove Theorem 1, we only need to verify

\[ \int_{-\infty}^{\infty} f_{\theta_s}(\theta_s) F_{\theta_s}(\theta_s) d\theta_s = \frac{1}{2}. \]

Substituting (11) into (23), we have

\[ \int_{-\infty}^{\infty} f_{\theta_s}(\theta_s) F_{\theta_s}(\theta_s) d\theta_s = \int_{-\infty}^{0} f_{\theta_s}(\theta_s) + \int_{0}^{\infty} f_{\theta_s}(\theta_s) d\theta_s. \]

\[ \int_{-\infty}^{0} f_{\theta_s}(\theta_s) + \int_{0}^{\infty} f_{\theta_s}(\theta_s) d\theta_s = \int_{0}^{\infty} f_{\theta_s}(\theta_s) d\theta_s = 1. \]

From (13), we observe that \( f_{\theta_s}(\theta_s) \) is an even function. Then, we have \( f_{\theta_s}(\theta_s) = f_{\theta_s}(-\theta_s) \). Meanwhile, we have

\[ \int_{-\infty}^{\infty} f_{\theta_s}(\theta_s) d\theta_s = \int_{-\infty}^{0} f_{\theta_s}(\theta_s) + \int_{0}^{\infty} f_{\theta_s}(\theta_s) d\theta_s = 1. \]

Thus, (24) can be rewritten as

\[ \int_{-\infty}^{\infty} f_{\theta_s}(\theta_s) F_{\theta_s}(\theta_s) d\theta_s = \int_{0}^{\infty} f_{\theta_s}(\theta_s) \left( 1 - \frac{1}{1+10^{\frac{\theta_s}{10}}} \right) d\theta_s = \int_{0}^{\infty} f_{\theta_s}(\theta_s) d\theta_s = \frac{1}{2}. \]

Here, we complete the proof of Theorem 1.
