Structural and Optimization Properties for Joint Selection of Source Rates and Network Flow
Bradford D. Boyle, Student Member, IEEE, and Steven Weber, Senior Member, IEEE

Abstract—We consider the optimal transmission of distributed correlated discrete memoryless sources across a network with capacity constraints. We present several previously undiscussed structural properties of the set of feasible rates and transmission schemes. We extend previous results concerning the intersection of polymatroids and contrapolymatroids to characterize when all of the vertices of the Slepian-Wolf rate region are feasible for the capacity constrained network. An explicit relationship between the conditional independence relationships of the distributed sources and the number of vertices for the Slepian-Wolf rate region are given. These properties are then applied to characterize the optimal transmission rate and scheme and its connection to the corner points of the Slepian-Wolf rate region. In particular, we demonstrate that when the per-source compression costs are in tension with the per-link flow costs the optimal flow/rate point need not coincide with a vertex of the Slepian-Wolf rate region. Finally, we connect results for the single-sink problem to the multi-sink problem by extending structural insights and developing upper and lower bounds on the optimal cost of the multi-sink problem.

Index Terms—Distributed source coding, minimum cost network flow, linear programming

I. INTRODUCTION

A. Motivation

A class of problems that arise in many contexts is the transmission of distributed discrete memoryless sources across a capacity-constrained network to a collection of sinks. Information theoretic characterizations of this class of problems has received much attention in recent years as a result of the development of network coding [2] and can be traced back to the seminal work of Slepian and Wolf [3]. In this paper, we consider the design problem of selecting a set of rates and a transmission scheme for a given network that are optimal with respect to known information-theoretic characterizations. A necessary assumption is that all sinks want all sources. The general case where each sink wishes to receive a subset of the sources has an implicit characterization in terms of the region of entropic vectors and only inner and outer bounds are explicitly known [4], [5].

B. Related Work

Han considers the problem of communicating a distributed set of correlated sources to a single sink across a capacity-constrained network and characterizes the set of achievable rates [6]. For a single sink, it is known that the min-cut/max-flow bounds can be achieved [5] and in particular, Slepian-Wolf (SW) style source coding [3] followed by routing is sufficient [6]. Han proposes a minimum-cost problem where link activations are charged a per unit cost and cites work by Fujishige [7] as an algorithmic solution to the proposed problem. The proposed algorithm can be applied to problems with both link and source costs; however, it cannot be extended to the case of multiple sinks. Additionally, the algorithm is only guaranteed to terminate in finite time if the data are assumed integral [7]. Barros et al. [8] contains a similar characterization of the set of achievable rates and an identical LP formulation as [6] but no discussion of an efficient algorithm.

In the achievability proof of Barros et al. (and Han [6]), a separation between the source encoder rates and the network flows is observed, leading to a natural mapping of this problem into the traditional protocol stack.

When the problem is extended from a single sink to multiple sinks, each sink required to receive all the sources, it is known that i) in general routing is not sufficient for achieving the min-

Fig. 1. Problem overview: A single sink node losslessly recovers distributed correlated sources over a capacity constrained network. There is a per unit cost associated with activating each link as well as a per unit cost at the sources.
cut/max-flow bounds; ii) network coding is necessary \[2\], and; iii) in fact linear network coding is sufficient \[5\]. Identical characterizations of when a distributed correlated source can be multicast across a capacity-constrained network have been given by Song et al., Ramamoorthy, and Han \[4\], \[9\], \[10\]. These characterizations are a natural extension of the result for a single sink \[6\]. Earlier work by Cristescu et al. also considers the problem of SW coding across a network with links that were not capacity-constrained \[11\]. This allows for an optimal solution to be obtained as the superposition of minimum weight spanning trees. Two key differences between the work of Ramamoorthy \[9\] and Han \[10\] are that the former makes the assumption of rational capacities to make use of results from \[12\] and specifically considers the problem of minimizing the cost to multicast the sources. Focusing on lossless communication and assuming a linear objective, the cost to multicast the sources can be formulated as a linear objective with per unit cost for activating links. By not having a per-source cost, the proposed LP can be solved by applying dual decomposition to exploit the combinatorial structure of the SW rate region associated with the correlated sources and using the subgradient method to approximate the optimal cost \[9\]. In the present work, we consider a more general model by including a per-unit rate cost for each source node. The technique of dual decomposition and application of the subgradient method has been used in work by Yu et al. \[13\] and Lun et al. \[14\]. Yu et al. considers the problem of lossy communication of a set of sources and minimizes a cost function that trades off between the estimation distortion and the transmit power of the nodes in the network. The rate-distortion region is, in general, not polyhedral and the resulting optimization problem is convex. Lun et al. makes the assumption of a single source and therefore does not deal with the interdependencies among the different source rates.

C. Summary of Contributions

Previous works have only considered the dual with respect to a subset of the constraints in order to exploit the contrapolytomatroidal structure of the SW rate region. In the present work, we restrict our attention to a single sink and more fully investigate the underlying combinatorial structure of the resulting set of achievable rates. By considering the full dual LP, we demonstrate the application of the additional structural properties towards the development of alternative algorithmic solutions.

The rest of the paper is organized as follows: In \[VI\] we present and discuss relevant supporting material from literature as well as formally pose our optimization problem. In \[VII\] we extend existing results concerning the intersection of polytomatroid with a contrapolytomatroid and characterize their types of intersections. We also relate the conditional independence relationships of the sources to degeneracy of the extreme points of the Slepian-Wolf rate region, reducing the number of inequality constraints needed to describe the polyhedron. In \[VI\] we consider the dual of the linear program to develop sufficient conditions for optimal solutions. We are particularly interested in knowing when the optimal solution will coincide with a vertex of the Slepian-Wolf rate region. We demonstrate that when there is an imbalance between the source costs and flow costs (i.e., cheap compression and expensive routing vs. expensive compression and cheap routing), the optimal rate allocation may not coincide with a vertex of the rate region. In \[VI\] we partially extend our results to the multi-sink problem and bound the optimal value of the multi-sink problem with the optimal values of related single sink problems. We conclude in \[VI\]

II. Preliminaries

We model the network as a simple directed graph \(D = (V, A)\) with nodes \(V\) representing alternately sources, routers, and destinations, and arcs \(A\) representing network connections between nodes in \(V\). We model the arcs \(A\) as capacitated with capacity \(c = (c(a), a \in A)\). If \(a = (u, v) \in A\), then we define \(\text{tail}(a) \triangleq u\) and \(\text{head}(a) \triangleq v\) and

\[
\delta^{\text{out}}(v) \triangleq \{a \in A : \text{tail}(a) = v\} \quad (1a)
\]

\[
\delta^{\text{in}}(v) \triangleq \{a \in A : \text{head}(a) = v\}. \quad (1b)
\]

For an arbitrary set function \(f : U \to \mathbb{R}\), we denote \(\sum_{u \subseteq B} f(u)\) by \(f(B)\) for any subset \(B \subseteq U\).

The distributed sources are located at a subset \(S \subseteq V\) of the network elements and need to be collected at a sink \(t \in V \setminus S\). We model the sources as a collection of correlated discrete memoryless random variables \((X_s : s \in S)\). There is a joint distribution \(p(X_{\mathcal{S}} : s \in S)\) (shortened to just \(p_S\)) on the set of sources which in turn gives rise to a vector of conditional entropies \((H(X_U|X_U^c), U \subseteq S)\), where \(H(X_U|X_U^c)\) is the conditional entropy associated with the subset of sources \(U \subseteq S\) given the values of the other sources \(U^c = S \setminus U\).

The decision variables in our model are both i) the rates for each source, \(R = (R(s), s \in S)\), and ii) the flow on each arc, \(f = (f(a), a \in A)\). The rate \(R(s)\) is the rate at which source \(s\) transmits, which must be routed (possibly split over multiple paths) towards the destination \(t\), and the flow \(f(a)\) is the superposition over all rates \(R(s)\) whose routes traverse arc \(a\). Flows must satisfy: i) capacity constraints (\(0 \leq f(a) \leq c(a)\) for all \(a \in A\)), and ii) conservation of flow at all non-source, non-sink nodes \((f(\delta^{\text{out}}(v)) = f(\delta^{\text{in}}(v))\) for all \(v \in V \setminus (S \cup \{t\})\)). A flow \(f\) supports rates \(R\) if for all \(s \in S\), \(R(s) = f(\delta^{\text{out}}(s)) - f(\delta^{\text{in}}(s))\). The novelty of our optimization problem model lies in jointly optimizing over both \((f, R)\) simultaneously, since most of the network flow literature assumes the source rates to be an input to the flow problem. While the multi-source network coding problem includes variables for both source rates and edge rates (analogous to our flow variables), much of the network coding literature has focused on characterizing the region obtained by projecting onto either the source rate or edge rate variables. Our work focuses on the cases where rate regions are known and expressly considers the problem of joint optimization without the projection onto one set of variables. For the case of multiple sinks, routing will no longer be sufficient and we will need to consider network coding. In this case, there will be a “virtual” flow \(f_t\) for each sink \(t\) satisfying the normal flow
constraints. Under network coding, the physical flow $f(a)$ on an arc $a$ will then satisfy $f_t(a) \leq f(a)$ for all $t$.

We begin with the Slepian-Wolf theorem, which characterizes the set of source rates for which lossless distributed source codes exist.

**Theorem 1** (Slepian-Wolf [3]). The rate region $R_{SW}$ for distributed lossless source coding the discrete memoryless sources $X_S$ is the set of rate tuples $R$ such that

$$R(U) \geq H(X_U | X_{S\backslash U}) \quad \forall \ U \subseteq S. \quad (2)$$

For brevity, let us define $\sigma_{SW} : 2^{|S|} \rightarrow \mathbb{R}$ as

$$\sigma_{SW}(U) \triangleq H(X_U | X_{U'}) \quad (3)$$

which is a nonnegative, nondecreasing supermodular set function on the set of sources. Note that the rate region of Theorem 1 is the contrapolyamatroid $Q_{\sigma_{SW}}$ associated with $\sigma_{SW}$:

$$R_{SW} = Q_{\sigma_{SW}} \triangleq \left\{ R \in \mathbb{R}^{|S|} : R(U) \geq \sigma_{SW}(U), \forall \ U \subseteq S \right\}. \quad (4)$$

The following theorem characterizes the set of source rates for which there exists a supporting flow.

**Theorem 2** (Megiddo [15]). There exists a flow $f$ that supports the rates $R$ iff

$$R(U) \leq \min\{c(\delta^{out}(X)) : U \subseteq X, t \in V \setminus X \} \quad \forall \ U \subseteq S. \quad (5)$$

Paralleling (5), define $\rho_c : 2^{|S|} \rightarrow \mathbb{R}$ as

$$\rho_c(U) = \min\{c(\delta^{out}(X)) : U \subseteq X, t \in V \setminus X \} \quad (6)$$

This is the min-cut capacity/max-flow value from the set $U$ to the sink $t$, which is a nonnegative, nondecreasing submodular set function on the set of sources. The set of source rates for which there exists a supporting flow is the polymatroid $P_{\rho_c}$ associated with $\rho_c$:

$$P_{\rho_c} \triangleq \left\{ R \in \mathbb{R}^{|S|} : R \geq 0, R(U) \leq \rho_c(U), \forall \ U \subseteq S \right\}. \quad (7)$$

The final theorem in this section characterizes when the intersection of the sets of source rates from the previous two theorems is non-empty.

**Theorem 3** (Han’s matching condition [6]). Let $\sigma$ and $\rho$ be supermodular and submodular set functions, respectively. Then

$$I_{\sigma, \rho} \triangleq Q_{\sigma} \cap P_{\rho} \neq \emptyset \quad (8)$$

if and only if

$$\sigma(U) \leq \rho(U) \quad \forall \ U \subseteq S \quad (9)$$

In particular, there exists distributed lossless source codes for communicating the sources $X_S$ across the capacity-constrained network to the sink $t$ iff $\sigma_{SW}(U) \leq \rho_c(U)$ for all $U \subseteq S$.

As mentioned in [6], the proof of the necessity of Theorem 3 is obvious. The proof of the sufficiency of Theorem 3 depends critically on the submodularity of $\rho$ and supermodularity of $\sigma$. Fig. 2 gives an example of generic set functions $\sigma$ and $\rho$ that satisfy $\sigma(U) \leq \rho(U)$ for all $U \subseteq S$. We see that $\rho$ is submodular since $\rho(U \cup V) \leq \rho(U) + \rho(V)$, while $\sigma$ is not supermodular since $\sigma(U \cup V) > \sigma(U) + \sigma(V)$.

In this case, Theorem 3 cannot be used to conclude that $P_{\sigma}$ and $Q_{\rho}$ have a non-empty intersection.

Fig. 2. An example of set functions $\rho$ and $\sigma$ that satisfy $\sigma(U) \leq \rho(U)$ for all $U \subseteq S$. We see that $\rho$ is submodular since $\rho(U \cup V) \leq \rho(U) + \rho(V)$, while $\sigma$ is not supermodular since $\sigma(U \cup V) > \sigma(U) + \sigma(V)$. In this case, Theorem 3 cannot be used to conclude that $P_{\sigma}$ and $Q_{\rho}$ have a non-empty intersection.
If $|A| + |V| - 1 + 2^{|S|}$ inequalities. If $|S| = O(|V|)$, then the LP is exponential in the size of the graph. Observe that an optimal solution $(f^*, R^*)$ to (11) will satisfy $R^*(S) = H(X_S)$ [6].

### III. Feasible Set Structural Properties

We see from Theorem [1] and Theorem [2] that the set of feasible rates $Q_{σ,ρ} \cap P_ρ$, is the intersection of a polymatroid with a contrapolymatroid. The resulting polytope can be thought of as being obtained by the projection $ρ : \mathbb{R}^{|A|+|S|} \to \mathbb{R}^{|S|}$ of the set of feasible $(f, R)$ tuples onto the rate variables $R$. In this section we present several structural properties of the set of feasible $(f, R)$ and the associated lower dimensional set $Q_{σ,ρ} \cap P_ρ$, that are independent of the assumed objective function in (11).

#### A. General properties from sub-/supermodularity

For any polyhedron $P$, we denote the set of extreme points as $\text{Ext}(P)$. The extreme points (vertices) of a contrapolymatroid $Q_σ$ are given by

$$R_σ(s_σ(i)) = σ(U_σ(i)) - σ(U_σ(i-1)) \quad i = 1, \ldots, |S|$$ (12)

where $σ$ ranges over all permutations of $[|S|]$ and $U_σ(i) = \{s_σ(1), \ldots, s_σ(i)\}$ [16]. The extreme rays of $Q_σ$ are the unit vectors of $\mathbb{R}^{|S|}$. Similarly, the extreme points of a polymatroid $P_ρ$ are given by

$$R_ρ(s_ρ(i)) = \begin{cases} ρ(U_ρ(i)) - ρ(U_ρ(i-1)) & i \leq k \\ 0 & i > k \end{cases}$$ (13)

where $π$ ranges over all permutations of $[|S|]$ and where $k$ ranges over $0, \ldots, |S|$ [16]. With these definitions, we can now show that the half-space inequalities for $U_σ(i)$ hold with equality.

**Lemma 1.** If $R_σ$ is the vertex of $Q_σ$ corresponding to permutation $π$ then

$$R_σ(U_σ(i)) = σ(U_σ(i)).$$ (14)

If $R_ρ$ is the vertex of $P_ρ$ corresponding to permutation $π$ then

$$R_ρ(U_ρ(i)) = ρ(U_ρ(i)).$$ (15)

**Proof:** See Appendix [A2].

The base polyhedron of $Q_σ$ and $P_ρ$ is defined as [17]

$$B_σ = Q_σ \cap \{R : R(S) = σ(S)\}$$ (16a)

$$B_ρ = P_ρ \cap \{R : R(S) = ρ(S)\}.$$ (16b)

As noted previously, an optimal solution $(f^*, R^*)$ to the LP (11) will satisfy $R^*(S) = H(X_S)$ and thus $R^* \in B_{σ,ρ}$.

In general, Han’s matching condition (Theorem [2]) does not allow us to conclude if the base polyhedron of a contrapolymatroid $B_σ$ is wholly contained in the intersection $Q_σ \cap P_ρ$.

**Example 1.** Consider $S = \{s_1, s_2\}$ and let $ρ$ be submodular and $σ$ supermodular such that $σ(U) ≤ ρ(U)$ for all $U ⊆ S$. Consider the vertex $R = (σ(s_1), σ(s_1, s_2) - σ(s_1))$ of $Q_σ$. We have, by the assumption of (9) that $R(s_1) = σ(s_1) ≤ ρ(s_1)$ and $R(s_1, s_2) = σ(s_1, s_2) ≤ ρ(s_1, s_2)$. From the supermodularity of $σ$, we have that $σ(s_2) ≤ σ(s_1, s_2) - σ(s_1)$ and by assumption $σ(s_2) ≤ ρ(s_2)$; this does not allow us to conclude one way or the other if $σ(s_1, s_2) - σ(s_1) ≥ ρ(s_2)$ and so we cannot, in general, determine if $R \in P_ρ$ and therefore $R \in I_{σ,ρ}$. Our first set of results characterize when $B_σ$ and $B_ρ$ are contained in $I_{σ,ρ}$. For generic submodular $ρ$ and supermodular $σ$ set functions we assume, w.l.o.g., that $σ(\emptyset) = ρ(\emptyset) = 0$. We begin by combining results from Frank et al. [18] and Fujishige [19, 17] and provide an explicit characterization of the vertices of $I_{σ,ρ}$ for certain instances of $σ$ and $ρ$.

**Theorem 4.** Let $σ$ be a supermodular set function and $ρ$ be a submodular set function. If

$$σ(U) - σ(U \setminus T) ≤ ρ(T) - ρ(T \setminus U) \quad ∀ T, U ⊆ S$$ (17)

then the vertices of $I_{σ,ρ}$ are given by

$$R^*_σ(s_σ(i)) = \begin{cases} ρ(U_σ(i)) - ρ(U_σ(i-1)) & i \leq j \\ σ(S \setminus U_σ(i-1)) - σ(S \setminus U_σ(i)) & i > j \end{cases}$$ (18)

where $π$ is a permutation and $j \in \{0, \ldots, n\}$.

**Proof:** See Appendix [A2].

Ignoring the flow costs in the LP of (11), we see that an optimal solution corresponds to an extreme point of $Q_{σ,ρ}$.

**Corollary 1.** Let $σ$ and $ρ$ satisfy the conditions of Theorem [4] and consider the LP given by

$$\begin{align*}
\text{minimize} & \quad \sum_{s \in S} h(s)R(s) \\
\text{subject to} & \quad σ(U) ≤ R(U) ≤ ρ(U) \quad U ⊆ S.
\end{align*}$$ (19)

If $h(s) ≥ 0$ for all $s \in S$, then there exists $R^* ∈ \text{Ext}(B_σ)$ that is an optimal solution to the given LP. If $h(s) ≤ 0$ for all $s \in S$, then there exists $R^* ∈ \text{Ext}(B_ρ)$ that is an optimal solution to the given LP.

For $σ$ and $ρ$ that satisfies the conditions of Theorem [4] the set $I_{σ,ρ}$ is a generalized polymatroid [18], a mathematical object that unifies polymatroids and contrapolymatroids [16]. For every generalized polymatroid in $\mathbb{R}^{|S|}$, there exists a submodular set function $ρ : 2^{|S|+1} \to \mathbb{R}$ and a projection $p : \mathbb{R}^{|S|+1} \to \mathbb{R}^{|S|}$ such that $p(B_ρ)$ is equal to that generalized polymatroid [17] (see Fig. 3a). This insight is half of the proof of Theorem [4]; the other half is recognizing that polyhedral properties are preserved by one-to-one affine mappings [19].

We see from (13) that the intersection $I_{σ,ρ}$ has at most $(n+1)!$ vertices; we can construct trivial examples for which the intersection is a generalized polymatroid and has strictly less than $(n+1)!$ vertices. For a given submodular set function $ρ$, let $σ(X) = ρ(S) - ρ(S \setminus X)$. It can be readily verified that such a $σ$ is supermodular and that (17) is always true by the submodularity of $ρ$. From (18), the vertices of $I_{σ,ρ}$ are just those of $B_ρ$ (or those of $B_ρ$ as $B_ρ = B_ρ$).

We observe that when (17) holds, we have that $B_σ \subset I_{σ,ρ}$ and $B_ρ \subset I_{σ,ρ}$. Motivated by the observation that if $(f^*, R^*)$ is an optimal solution to (11), then $R^* \in B_{σ,ρ}$, we loosen
The requirement (17) of Theorem 4 to characterize when $B_\sigma \subseteq I_{\sigma, \rho}$.

**Theorem 5.** $\text{Ext}(B_\sigma) \subseteq P_\rho$ if and only if

$$\sigma(T) - \sigma(T \setminus U) \leq \rho(U) \quad \forall U \subseteq T \subseteq S.$$  

*Proof:* See Appendix 4.

Unsurprisingly, we can loosen (17) in a similar manner to characterize when $B_\rho \subseteq I_{\sigma, \rho}$.

**Theorem 6.** $\text{Ext}(B_\rho) \subseteq Q_\sigma$ if and only if

$$\sigma(U) \leq \rho(T) - \rho(T \setminus U) \quad \forall U \subseteq T \subseteq S.$$  

*Proof:* See Appendix 4.

Observe that Theorems 4, 5, and 6 each imply Theorem 3. To see this, let $T = U$. Fig. 4 provides an example that illustrates the differences between Theorems 3, 4, 5, & 6. Theorem 3 provides an initial characterization of the structure of $I_{\sigma, \rho}$ by determining when the intersection is empty or not and requires checking $2^n$ inequalities. It does not provide insight into what the vertices of the intersection are. Theorem 5 and Theorem 6 provide a partial characterization of the vertices of the intersection by characterizing a subset of the vertices of the intersection, but each requires checking $3^n$ inequalities. If $\text{Ext}(B_\sigma) \subseteq P_\rho$, then $\text{Ext}(B_\rho) \subseteq \text{Ext}(I_{\sigma, \rho})$ and if $\text{Ext}(B_\rho) \subseteq Q_\sigma$, then $\text{Ext}(B_\rho) \subseteq \text{Ext}(I_{\sigma, \rho})$. However, we know that there are vertices of $I_{\sigma, \rho}$ that do not lie in either $B_\sigma$ or $B_\rho$ (e.g., Fig. 4c). Finally, Theorem 4 provides a complete characterization of $\text{Ext}(I_{\sigma, \rho})$, but requires checking $4^n$ inequalities. Observe that $U \cap T = \emptyset$ the cross inequality (17) of Theorem 4 is the tautology $0 \leq 0$ and there are $3^n$ such pairs $T, U$ of subsets of $S$. For $T = U$, (17) becomes Han’s matching condition (19). For $T \subseteq U$, (17) reduces to (20). For $U \subseteq T$, (17) reduces to (21). The relationship among Theorems 1, 2, 3, and 4 (in terms of pairs of subsets of $S$) is depicted in Fig. 5.

We now show that characterizing $B_\sigma \subseteq I_{\sigma, \rho}$ only requires checking $2^n$ inequalities, as opposed to the $3^n$ inequalities of Theorem 3.

**Theorem 7.**

$$\sigma(T) - \sigma(T \setminus U) \leq \rho(U) \quad \forall U \subseteq T \subseteq S$$  

if and only if

$$\sigma(S) - \sigma(S \setminus U) \leq \rho(U) \quad \forall U \subseteq S.$$  

Specializing the cross-inequality (17) of Theorem 4 for $T = U$ gives Theorem 8 for $T \subseteq U$ gives Theorem 5 and for $U \subseteq T$ gives Theorem 6.
Consider a set of sources $H$ requires the network have enough capacity to support the rate (i.e., maximum) for all subsets of sources.

The matching condition (23) of Theorem 7 requires that the network have enough capacity to support the worst-case sum-rate of (23) and (25). For a given supermodular set function $\rho_c$ if and only if $\rho_c(U)$ to support the “highest” sum-rate $H(X_U \mid X_{U^c})$ from every subset of sources. Specializing (25) to conditional entropy and min-cut capacity requires the network to have enough capacity $\rho_c(U)$ to support the “highest” sum-rate $H(X_U)$ from every subset of sources. The sum-rate from a subset of sources could exceed the entropy, but is not needed to support lossless recovery of the sources and would be a suboptimal rate allocation.

We now specialize (25) for the case of conditional entropy $\sigma_{SW}$ and min-cut capacity $\rho_c$.

$$H(X_U) \leq \rho_c(U) \forall U \subseteq S,$$

which follows from the application of the chain rule for entropy to $H(X_S) - H(X_{S \setminus U} \mid X_U)$. Fig. 7 illustrates the differences between Theorem 3 and Theorems 7 and 8.

Consider a set of sources $U$. Han’s matching condition [19] requires the network have enough capacity to support the best-case sum-rate (i.e., minimum) from a set of sources for lossless recovery; in particular $H(X_U \mid X_{U^c}) \leq \rho_c(U)$. The matching condition (23) of Theorem 7 requires that the network have enough capacity to support the worst-case sum-rate (i.e., maximum) for all subsets of sources.

Unlike Theorem 3 when we specialize (17) to the case of conditional entropy and min-cut capacity there is no immediately obvious intuition for what (27) represents.

$$H(X_{U \mid CT} \mid X_{U^c}) \leq \rho_c(T) - \rho_c(T \setminus U)$$

B. Properties from conditional entropy

In the previous section, we focused on the properties of general submodular and supermodular set functions in order to more fully characterize the intersection of a polymatroid with a contrapolyomatroid. Our next set of results leverage additional properties of the conditional entropy supermodular set function, most notably the chain rule for entropy and the relationship between entropy and conditional independence [20]. To motivate the results of this section, consider the two source SW rate regions in Fig. 8. In general, the rate region is defined by three inequalities as in Fig. 8a; however, if it is known that the sources are independent (i.e., $X_1 \perp X_2$), the rate region can be defined using only two inequalities. The number of vertices has also been reduced from two non-degenerate vertices to one degenerate vertices. We further develop this insight in the remainder of this section.

For an extreme point $R$ of $Q_{\sigma_{SW}}$, we provide an expression for the sum rate for an arbitrary set of sources and then use this to characterize the active inequalities of the LP (11) at $R$.

**Lemma 2.** Fix an ordering $s_1, s_2, \ldots, s_n$ of the elements of $S$ and define $U_i \triangleq \{s_j : j \in [i]\}$. If $R$ is the vertex in $Q_{\sigma_{SW}}$ corresponding to this ordering and $U = \{s_{k_1}, \ldots, s_{k_m}\}$ such that $k_1 < k_2 < \ldots < k_m$ then

$$R(U) = H(X_U \mid X_{U_{k_1}})$$

$$+ \sum_{j=2}^{m} I(X_{U \setminus U_{k_{j-1}}} \mid X_{U_{k_{j-1}}} \setminus X_{U_{k_{j}}}, U_{k_{j}})$$

**Proof:** See Appendix A7.

**Proposition 1.** Fix an ordering $s_1, s_2, \ldots, s_n$ of the elements of $S$ and define $U_i \triangleq \{s_j : j \in [i]\}$ and $U_0 = \emptyset$. Let $R$ be
Example 2. Consider the following three source discrete random variables $(X_1, X_2, X_3)$ such that $X_1 \perp X_2 \perp X_3$. Define $P(X_1 = x_1, X_2 = x_2) = \begin{cases} 1 - \frac{p}{2} & x_1 = x_2 \\ \frac{p}{2} & x_1 \neq x_2 \end{cases}$ and 

$P(X_3 = 0 \mid X_2 = 0) = P(X_3 = 1 \mid X_2 = 1) = 1 - q$.

with $p, q \neq \frac{1}{2}$. Such a DMS forms the Markov chain $X_1 \leftrightarrow X_2 \leftrightarrow X_3$. For the permutation $\pi = (3, 1, 2)$, we have the

three necessarily active constraints

$R_\pi(s_3) = H(X_3 \mid X_1, X_2)$

$R_\pi(s_1, s_3) = H(X_1, X_3 \mid X_2)$

$R_\pi(s_1, s_2, s_3) = H(X_1, X_2, X_3)$. 

Additionally, because of the Markov structure for this source we have

$R_\pi(s_1) = H(X_1 \mid X_2) = H(X_1 \mid X_2, X_3)$

active at $R_\pi$. Enumerating all of the vertices, we see that the Slepian-Wolf rate region for this class of DMSs has only five vertices instead of $3! = 6$. In particular, the permutations $\pi_1 = (1, 3, 2)$ and $\pi_2 = (3, 1, 2)$ map to the same point, i.e., $R_{\pi_1} = R_{\pi_2}$.

If $p = \frac{1}{2}$ or (exclusively) $q = \frac{1}{2}$, then the SW rate region will only have four vertices. If $p = q = \frac{1}{2}$, then the SW rate region will have one vertex. Fig. 9 shows the number of vertices that SW rate region has and summarizes the different conditional independence structures as a function of the distribution parameters $p$ and $q$.

Proposition 1 will be used in the next section when giving conditions for a feasible solution of the optimization problem $\Pi$ to be optimal.

IV. SUFFICIENT CONDITIONS FOR CHARACTERIZING OPTIMALITY

We proceed by finding the dual LP of the primal given in $\Pi$. In $\Pi$, we have three types of constraints: i) a capacity constraint for each edge, ii) flow conservation for each node, and iii) rate requirements for each subset of sources. The dual, then, will have three types of dual variables: i) $(x(a) : a \in A)$, ii) $(z(v) : v \in V)$, and iii) $(y_{U} : U \subset S)$. The dual LP is given as

\[
\begin{align*}
\text{maximize} & \quad \sum_{a \in A} c(a)x(a) + \sum_{U \subseteq S} H(X_U \mid X_{\bar{U}})y_{U} \\
\text{subject to} & \quad x(a) + z(\text{head}(a)) - z(\text{tail}(a)) \leq k(a) \quad a \in A \\
& \quad \sum_{U \ni s} y_{U} + z(s) - z(t) = h(s) \quad s \in S
\end{align*}
\]

(35)

We set $z(t) = 0$ because it is associated with the conservation of flow constraint at the sink, which is omitted from $\Pi$ as
it is a consequence of the equality constraints at every other node. Observe that the number of dual variables is exponential in $|S|$. We now show that, in a certain sense, the dual variables $x(a)$ for $a \in A$ and $y_U$ for $U \subseteq S$ are unnecessary.

Let us define the reduced cost of $a \in A$ as

$$
\tilde{k}(a) \triangleq k(a) - (z(\text{head}(a)) - z(\text{tail}(a)))
$$

and observe that the first set of constraints of (35) can be written as $x(a) \leq \tilde{k}(a)$ for all $a \in A$ (22). Combined with the non-negativity constraint on $x(a)$ we have $x(a) \leq \min(0, \tilde{k}(a))$. Since we are maximizing in (35) and $c(a) > 0$ for all $a$, we take

$$
x(a) = \min(0, \tilde{k}(a))
$$

and see that the dual variable $x(a)$ can be expressed in terms of $(z(v) : v \in V)$. As we show in the next theorem, characterizations of optimal solutions do not need to explicitly consider the dual variables $(x(a) : a \in A)$.

**Theorem 9.** Let $f^*_R$ be a min-cost flow that supports rate $R$. Let $R = \sum_i \lambda_i R_i$. The flow $f = \sum_i \lambda_i f^*_R_i$ is a flow that supports $R$ of minimum cost if there exists a vector $(z(v) : v \in V)$ such that for all $i$

$$
k(a) < 0 \implies f^*_R_i(a) = c(a) \quad (38a)
$$

$$
k(a) > 0 \implies f^*_R_i(a) = 0. \quad (38b)
$$

**Proof:** See Appendix A10

Since we are considering fixed rates in the previous theorem, there are no dual variables $(y_U : U \subseteq S)$. If the conditional entropies of the sources and the min-cut capacities satisfy the requirements of Theorem 4, then all extreme points of $Q(\sigma_{SW})$ are feasible for (11). As was mentioned earlier, if $(f^*, R^*)$ is an optimal solution to (11) then $R^*(S) = H(X_S)$ and therefore $R^*$ can be written as a convex combination of the extreme points of $Q(\sigma_{SW})$. The previous theorem shows that in certain cases, $f^*$ can be found as a convex combination of the min-cost flows for the extreme points of the SW rate region. In general though, this is not always the case as the next example demonstrates.

**Example 3.** We consider the relay network with arc capacities and costs as shown in Fig. 10a. Let the sources $X_1, X_2$ be binary valued with the following joint distribution

$$
P(X_1 = x_1, X_2 = x_2) = \begin{cases} 
\frac{1-p}{2} & x_1 = x_2 \\
\frac{p}{2} & x_1 \neq x_2.
\end{cases}
$$

(39)

For such a source, the entropies are $H(X_1) = H(X_2) = 1$ and $H(X_1, X_2) = 1 + H(p)$ and the vertices of the Slepian-Wolf rate region are $R_1 = (H(p), 1)$ and $R_2 = (1, H(p))$. The network of Fig. 10a has sufficient capacity to support either $R_1$ or $R_2$. Fixing $R = R_1$ and solving for the min-cost flow $f^*_1$, we obtain the solution shown in Fig. 10b. Correspondingly, if we fix $R = R_2$ and solve for the min-cost flow $f^*_2$, we obtain the solution shown in Fig. 10c. The feasible solution $f_\lambda = \lambda f^*_1 + (1 - \lambda) f^*_2$ for $R_3 = \lambda R_1 + (1 - \lambda) R_2$ is shown in Fig. 10d. Comparing with optimal min-cost flow $f^*_\lambda$ for $R_\lambda$

$$
\text{shown in Fig. 10c & Fig. 10d we see that for } \lambda \in (0, 1), \text{ the convex combination of min-cost flows } f_\lambda \text{ is not a min-cost flow for } R_\lambda. \text{ Shown in Fig. 11 is the cost } k^T f_\lambda \text{ of the convex combination of min-cost flows as a function of } \lambda \text{ compared to the cost } k^T f^*_\lambda \text{ for the min-cost flow for a convex combination of rates } R_\lambda. \text{ Comparing Fig. 10d with Fig. 10c & Fig. 10d we see immediately why } f_\lambda \text{ is not optimal: } f_\lambda \text{ always utilizes the arc } a_3 \text{ even when arc } a_1 \text{ (which has a lower cost) has spare capacity. If the same relay network is considered with } k = (2, 1, 1) \text{ and all other parameters kept the same, then it can be shown that } k^T f_\lambda = k^T f^*_\lambda \text{ for } \lambda \in [0, 1]. \text{ Observe that with this cost vector } k, \text{ the cost of the two directed paths } s_1 \rightarrow t \text{ are } k(a_1) = 2 \text{ and } k(a_3) + k(a_2) = 2 \text{ and the cost of any flow supporting } R(s_1) \text{ is the same.}
$$

A sufficient condition for the existence of $z$ that satisfies the condition of Theorem 2 can be given in terms of the topology of the network and the arc costs $k$.

**Theorem 10.** If for every $v \in V \setminus \{t\}$, the cost of all $v - t$ paths are equal, then there exists a vector $(z(v) : v \in V)$ such that for

$$
k(a) < 0 \implies f^*_R_i(a) = c(a) \quad (40a)
$$

$$
k(a) > 0 \implies f^*_R_i(a) = 0. \quad (40b)
$$

**Proof:** See Appendix A11

We now define the reduced cost of $s \in S$ as

$$
h(s) \triangleq h(s) - (z(s) - z(t)) = h(s) - z(s)
$$

(41)

and rewrite the second set of constraints of (35) as

$$
\sum_{U \subseteq S} y_U = h(s).
$$

(42)

We seek to express the dual variables $y_U$ as a function of the dual variables $z(s)$ as we did for the dual variables $x(a)$. The following theorem provides a characterization of which of the dual variables $y_U$ must be zero as a function of the correlation structure of the source random variables.

**Theorem 11.** Suppose $R^*$ is primal optimal and $y^*$ is dual optimal and let $U = \{s_{k_1}, \ldots, s_{k_m}\}$ such that $k_1 < k_2 < \cdots < k_m$. If $R^*$ is a vertex of $Q_{\sigma_{SW}}$ and there exists $j \in [m]$ such that

$$
(X_U \setminus U_{s_{j-1}} \not\subseteq X_{U_{s_{j-1}} \setminus U_{s_{j-1}}}) \setminus (X_U \setminus U_{s_j}) \setminus U
$$

(43)
then \( y^*_U = 0 \).

**Proof:** Follows immediately from complimentary slackness and Proposition 1.

This characterization suggests the following sufficient condition for an extreme point \( R_\pi \) of the SW rate region \( Q_{\pi,SW} \) and its associated min-cost flow \( f^*_\pi \) to be a solution to the LP in (11).

**Theorem 12.** A feasible solution \((f^*_\pi, R_\pi)\) of (11) is optimal if there exists vectors \((z(v) : v \in V)\) satisfying
\[
\begin{align*}
\bar{k}(a) < 0 \implies f^*_\pi(a) = c(a) & \quad \forall a \in A \quad (44a) \\
\bar{k}(a) > 0 \implies f^*_\pi(a) = 0 & \quad \forall a \in A \quad (44b)
\end{align*}
\]
and
\[
\bar{h}(s_1) \geq \bar{h}(s_2) \geq \cdots \geq \bar{h}(s_n) \geq 0 \quad (45)
\]
where the elements of \( S \) are ordered according to the permutation \( \pi \).

**Proof:** See Appendix A12.

The impact of the previous two theorems is that even though the dual has an exponential number of variables, we need only consider a linear \(|V|\) number of them. Given \((z^*(v) : v \in V)\), we can compute \((x^*(a) : a \in A)\) according to (37) and \((y^*_U : U \subseteq S)\) according to (91). The extreme points of the SW rate region are significant because codes that satisfy \( R(S) = H(X_S) \) can be constructed from codes for these points via time sharing. By adding in a per source cost to the previous example, we demonstrate that such a \( z \) need not always exist.

**Example 4.** Looking at Fig. 11 one might conjecture that an optimal solution \((f^*, R^*)\) to problem \((11)\) would have the property \( R^* \in \text{Ext}(B_{\pi,SW}) \); i.e., that an optimal rate will always coincide with a vertex of the Slepian-Wolf rate region and that \( z \) that satisfies the condition of the previous theorem will always exist. It is certainly true that \( f^*, R^* \) will be a vertex of the polyhedron in flow-rate space, the network of Fig. 11 example demonstrates that for certain choices of source costs \( h \) and arc costs \( k \) the optimal rate \( R^* \) need not be a vertex of the Slepian-Wolf rate region. Fig. 12 shows the cost \( h^TR_\lambda + k^Tf^*_\lambda \) of the convex combination of min-cost flows as a function of \( \lambda \) compared to the cost \( h^TR_\lambda \) for the min-cost flow for a convex combination of rates \( R_\lambda \). We see immediately the minimum cost is achieved with \( \lambda = \frac{1}{2} \) and \( R_\lambda \notin \text{Ext}(B_{\pi,SW}) \).

Given the intuitive decomposition of the source coding and routing into different protocol layers noted by Barros et
al., it may appear at first glance that a simple decomposed approach to designing a minimum cost solution might hold \[8\]. For the case where all extreme points of the Slepian-Wolf rate region are feasible, one might consider a naive approach of finding a minimum cost (w.r.t. \( R \)) source rate \( \tilde{R} \) and a supporting minimum cost (w.r.t. \( k \)) \( \tilde{f} \). Alternatively, one might try enumerating all extreme points of the Slepian-Wolf rate region (combinatorial complexity aside), solving for a min-cost flow, and keeping track of the best solution. The problem with both of these approaches is that the resulting feasible solution will select a rate \( \tilde{R} \) that coincides with an extreme point of the Slepian-Wolf rate region. The previous example demonstrates that when there is an imbalance between source costs and flow cost (i.e., cheap compression and expensive routing vs. expensive compression and cheap routing) the optimal rate \( R^* \) is a valid flow that supports \( \tilde{R} \) for the sink \( t \).

Theorem 13 (Han’s Matching Condition for Multiple Sinks \[10\]). The sources \( X_S \) are transmissible across the network to the sinks \( T \) if and only if

\[
\sigma_{SW}(U) \leq \min_{\tilde{f}(t)} \rho^*_c(U) \forall U \subseteq S. \tag{50}
\]

Comparing \[9\] and \[50\], we see that Theorem 13 implies Theorem 3 for every sink \( t \in T \). We can extend Theorem 5 in a similar manner.

Theorem 14. All of the vertices of the Slepian-Wolf rate region \( Q_{\sigma_{SW}} \) are feasible for the multi-sink problem \[46\] if and only if

\[
H(X_U) \leq \min_{\tilde{f}(t)} \rho^*_c(U) \forall U \subseteq S. \tag{51}
\]

Proof: See Appendix A13.

We can bound the optimal value of the multi-sink min-cost flow problem in \[46\] in terms of the optimal values for a collection of single-sink min-cost flow problems.

Theorem 15. Let \((f^*, p^*, R^*)\) be an optimal solution to \[46\] and \((\tilde{f}(t), \tilde{R}(t))\) be an optimal solution to the single sink problem for \( t \in T \). We have

\[
\max_{t \in T} \sum_{a \in A} k(a) \tilde{f}(t)(a) \leq \sum_{a \in A} k(a) p^*(a) \tag{52}
\]

and

\[
\sum_{a \in A} k(a) p^*(a) \leq \sum_{a \in A} k(a) \max_{t \in T} \tilde{f}(t)(a). \tag{53}
\]

Proof: See Appendix A14.

Example 5. As an example of the above bounds, we consider a multi-sink problem instance formulated by Ramamoorthy \[9\]. In this scenario, the network consists of 50 nodes and 286 edges; 10 of the nodes are sources and 3 are sinks, with the rest of the nodes acting as relays. The edge capacities are either 20 or 40 depending upon the distance between the connected nodes and the edge costs are all 1. A more detailed

\[
\begin{align*}
\text{Fig. 12. Plot of i) source cost plus cost of a convex combination of min-cost flows and ii) source cost plus the cost of a min-cost flow for a convex combination of rates. The source distribution parameter } p = \frac{1}{2}.
\end{align*}
\]
description of the network topology and source model can be found in [9], §3-B. Shown in Fig. 13 is a comparison of the cost of the solution found using a partial dual decomposition and application of the subgradient method, the optimal value as computed from building and solving the LP in (46), and the lower and upper bounds of Theorem 15. We observe, for this problem, that neither bound is tight; the lower bound has a relative difference of 47.5% while the upper bound has a relative difference of 34.7%. We see that the subgradient method does converge to the optimal value rather quickly, realizing a relative error of 0.19%, 0.13%, and 0.06% after 10, 100, and 1000 iterations, respectively.

VI. CONCLUSION

In this paper, we have considered the transmission of distributed sources across a network with capacity constraints. Previous works have only made use of the fact that SW rate region is a contrapolytoematroid as part of an iterative subgradient method. The set of achievable rates is the intersection of the SW rate region with the polytoematroid defined by the min-cut capacities. We characterize when the SW vertices are all feasible and give an explicit characterization of all the vertices of the intersection of polytoematroid with a contrapolytoematroid for certain sub/supermodular set functions. The size of the representation of the SW rate region is related to the conditional independence relationships among the sources and in some cases may require a sub-exponential number of inequalities to describe the rate region. We have shown that these properties lead to a characterization relating optimal solutions and the corner points of the SW rate region. Through a simple, but natural counter-example we demonstrate that an optimal rate allocation may not be a vertex of the SW rate region. Our result concerning the feasibility of all the SW rate region vertices naturally extends from the single sink problem to the multi-sink setting. The optimal value of the multi-sink is bounded from above and below in terms of the optimal solutions to a collection of related single-sink problems.

A. Included Proofs

1) Proof of Lemma [7]

Proof: For any supermodular set function we have

\[ R_\pi(U_{\pi(i)}) = \sum_{j=1}^{i} R_\pi(s_{\pi(j)}) = \sum_{j=1}^{i} \sigma(U_{\pi(j)}) - \sigma(U_{\pi(j-1)}) = \sigma(U_{\pi(i)}) - \sigma(\emptyset). \]  

For any submodular set function we have

\[ R_\pi(U_{\pi(i)}) = \sum_{j=1}^{i} R_\pi(s_{\pi(j)}) = \sum_{j=1}^{i} \rho(U_{\pi(j)}) - \rho(U_{\pi(j-1)}) = \rho(U_{\pi(i)}) - \rho(\emptyset). \]  

2) Proof of Theorem [4]

Lemma 3. Let Ext(P) be the set of extreme points of a polyhedron P and p(P) be the projection of P; then Ext(p(P)) \(\subseteq\) p(Ext(P)).

Proof: Suppose \(x \in\) Ext(p(P)); then there exists \(x'\) such that \((x, x') \in P\). As x is extreme, there does not exist \(y, z \in\) P not equal to x and \(\lambda \in (0, 1)\) such that \(x = \lambda y + (1-\lambda)z\). Therefore there is no choice of \((y, y'), (z, z') \in P\) not equal to \((x, x')\) and \(\lambda \in (0, 1)\) such that

\[ \left(\frac{x}{x'}\right) = \lambda \left(\frac{y}{y'}\right) + (1-\lambda) \left(\frac{z}{z'}\right) \]  

and \((x, x') \in\) Ext(P).

Lemma 4. Let Ext(P) be the set of extreme points of a polyhedron P and p(P) be the projection of P. If p one-to-one, then Ext(p(P)) = p(Ext(P)).

Proof: Consider \(x \in\) Ext(P); suppose its projection \(p(x) \notin\) Ext(p(P)). W.l.o.g. there exists \(y, z \in P\) not equal to x and \(\lambda \in (0, 1)\) such that

\[ p(x) = \lambda p(y) + (1-\lambda)p(z) = \rho(\lambda y + (1-\lambda)z) \]  

which follows from projections being affine mappings. Additionally, since the projection is one-to-one we must have

\[ x = \lambda y + (1-\lambda)z \]  

contradicting the assumption of \(x \in\) Ext(P).

Proof: Assuming \(\sigma\) and \(\rho\) satisfy the condition of Theorem [4] we have that \(Q_\sigma \cap P_\rho\) is non-empty. Let us define \(S' = S \cup \{s^*\}\) and

\[ f(U) = \begin{cases} \rho(U) & U \in 2^S \\ \gamma - \sigma(S' \setminus U) & U \subset S', s^* \in U \end{cases} \]  

where \(\gamma \in \mathbb{R}\) is arbitrary but fixed. Such a \(f\) is a submodular function on \(2^S\) and \(B(EP_f) = EP_f \cap \{ R: R(S) = f(S) \}\) is non-empty [7]. In fact

\[ Q_\sigma \cap P_\rho = \left\{ R \in \mathbb{R}^{|S'|}: \exists \alpha \in \mathbb{R}: (R, \alpha) \in B(EP_f) \right\}. \]  

The vertices of \(EP_f\) are given by

\[ R_\pi(s_{\pi(i)}) = f(U_{\pi(i)}) - f(U_{\pi(i-1)}) \quad i = 1, \ldots, |S| + 1 \]  

where \(\pi\) ranges over all permutations of \(|S| + 1\). Let \(j\) be the integer such that \(s_{\pi(j)} = s'\). Then

\[ R_\pi(s_{\pi(i)}) = \begin{cases} \rho(U_{\pi(i)}) - \rho(U_{\pi(i-1)}) & i < j \\ \gamma - \sigma(S' \setminus U_{\pi(i)}) - \rho(U_{\pi(i-1)}) & i = j \\ \sigma(S' \setminus U_{\pi(i-1)}) - \sigma(S' \setminus U_{\pi(i)}) & i > j. \end{cases} \]  

3) Proof of Theorem [5]

Proof: Assume \(\sigma(T) - \sigma(T \setminus U) \leq \rho(U)\) for all \(U \subseteq T \subseteq S\). Consider an arbitrary permutation \(\pi\) and its associated vertex \(R_\pi\) of \(Q_\sigma\). For any \(U \subseteq S\), define \(k \triangleq \min\{k' : U \subseteq \pi(k')\}\) or equivalently \(k \triangleq \max\{k' : s_{\pi(k')} \in U\}\). We have

\[ R_\pi(U) = R_\pi(U_{\pi(k)}) - R_\pi(U_{\pi(k)} \setminus U) \]  

and therefore \(R_\pi \in P_\rho\). This is true for all permutations and we conclude that \(B(Q_\sigma) \subseteq P_\rho\).

Suppose \(\exists U \subseteq T \subseteq S\) such that \(\sigma(T) - \sigma(T \setminus U) \geq \rho(U)\). Let the elements of \(S\) be ordered by a permutation \(\pi\) so that \(T = \{s_{\pi(1)}, \ldots, s_{\pi(|T|)}\}\) and \(U = \{s_{\pi(|T|)-|U|+1}, \ldots, s_{\pi(|T|)}\}\). Then \(T = U_{\pi(|T|)}\) and \(T \setminus U = U_{\pi(|T|) \setminus |U|}\). It follows that

\[ R_\pi(U) = \sum_{i=|T|\setminus |U|+1}^{T} \sigma(U_{\pi(T)}) - \sigma(U_{\pi(i)}) = \sigma(T) - \sigma(T \setminus U) > \rho(U) \]  

and therefore \(R_\pi \notin P_\rho\). We conclude that \(B_\sigma \subseteq P_\rho\).

4) Proof of Theorem [6]

Proof: Assume \(\sigma(U) \leq \rho(T) - \rho(T \setminus U)\) for all \(U \subseteq T \subseteq S\). Consider an arbitrary permutation \(\pi\) and its associated vertex \(R_\pi\) of \(P_\rho\). For any \(U \subseteq S\), define \(k \triangleq \min\{k' : U \subseteq s_{\pi(k')}\}\) or equivalently \(k \triangleq \max\{k' : s_{\pi(k')} \in U\}\). We have

\[ R_\pi(U) = R_\pi(U_{\pi(k)}) - R_\pi(U_{\pi(k)} \setminus U) \]  

where \(\gamma \in \mathbb{R}\) is arbitrary but fixed. Such a \(f\) is a submodular function on \(2^S\) and \(B(EP_f) = EP_f \cap \{ R : R(S) = f(S) \}\) is non-empty [7]. In fact

\[ Q_\sigma \cap P_\rho = \left\{ R \in \mathbb{R}^{|S'|} : \exists \alpha \in \mathbb{R} : (R, \alpha) \in B(EP_f) \right\}. \]  

The vertices of \(EP_f\) are given by

\[ R_\pi(s_{\pi(i)}) = f(U_{\pi(i)}) - f(U_{\pi(i-1)}) \quad i = 1, \ldots, |S| + 1 \]  

where \(\pi\) ranges over all permutations of \(|S| + 1\). Let \(j\) be the integer such that \(s_{\pi(j)} = s'\). Then

\[ R_\pi(s_{\pi(i)}) = \begin{cases} \rho(U_{\pi(i)}) - \rho(U_{\pi(i-1)}) & i < j \\ \gamma - \sigma(S' \setminus U_{\pi(i)}) - \rho(U_{\pi(i-1)}) & i = j \\ \sigma(S' \setminus U_{\pi(i-1)}) - \sigma(S' \setminus U_{\pi(i)}) & i > j. \end{cases} \]  

The set \(EP_f = \{ R \in \mathbb{R}^{|S'|} : R(U) \leq f(U) \}\) is the extended polymatroid associated with \(f\) while \(P_f = \{ x \in \mathbb{R}^{|S'|} : R \geq 0, R(U) \leq f(U) \}\) is the polymatroid associated with \(f\).
and therefore \( R_\pi \in Q_\sigma \). This is true for all permutations and we conclude that
\( B(R_\pi) \subseteq Q_\sigma \).

Suppose \( \exists U \subseteq T \subseteq S \) such that \( \sigma(U) > \rho(T) - \rho(T \setminus U) \). Let the elements of \( S \) be ordered by a permutation \( \pi \) so that \( T = \{ s_{\pi(1)}, \ldots, s_{\pi(|T|)} \} \) and \( U = \{ s_{\pi(|T|)-|U|+1}, \ldots, s_{\pi(|T|)} \} \). Then \( T = U_{\pi(|T|)} \) and \( T \setminus U = U_{\pi(|T|)-|U|} \).

It follows that
\[
R_\pi(U) = \sum_{i=|T|-|U|+1}^{|T|} \rho(U_{\pi(i)}) - \rho(U_{\pi(i-1)})
= \rho(U_{\pi(|T|)}) - \rho(U_{\pi(|T|)-|U|})
= \rho(T) - \rho(T \setminus U)
< \sigma(U)
\]
and therefore \( R_\pi \notin Q_\sigma \). We conclude that \( B(R_\pi) \subseteq Q_\sigma \).

**Remark.** In the proofs of Theorems 3 \& 8 we use the existence of \( T, U \) that do not satisfy (20) (resp. (21)) to construct a vertex of \( Q_\sigma \) (resp. \( R_\pi \)) that is not retained in the intersection \( I_{\sigma,\rho} \). For a given \( T, U \) that do not satisfy (20), there exists \((|T| - |U|)!|U|!(|S| - |T|)! \) permutations for which the corresponding vertex of \( Q_\sigma \) is not in \( P_\rho \). Similarly, for a given \( T, U \) that do not satisfy (21), there exists \((|T| - |U|)!|U|!(|S| - |T|)! \) permutations for which the corresponding vertex of \( P_\rho \) is not in \( R_\pi \).

5) **Proof of Theorem 7**

**Proof:** The set of inequalities in (22) include (23), so the one direction is immediate.

By the supermodularity of \( \sigma \), we have
\[
\sigma(T) + \sigma(S \setminus U) \leq \sigma(S) + \sigma(T \setminus U) \forall U \subseteq T \subseteq S
\]
which we rearrange to get
\[
\sigma(T) - \sigma(T \setminus U) \leq \sigma(S) - \sigma(S \setminus U) \leq \rho(U) \forall U \subseteq T \subseteq S
\]

6) **Proof of Theorem 8**

**Proof:** The set of inequalities in (24) include (25), so the one direction is immediate.

By the submodularity of \( \rho \), we have
\[
\rho(S) + \rho(T \setminus U) \leq \rho(T) + \rho(S \setminus U) \forall U \subseteq T \subseteq S
\]
which we rearrange to get
\[
\sigma(U) \leq \rho(S) - \sigma(S \setminus U) \leq \rho(T) - \rho(T \setminus U) \forall U \subseteq T \subseteq S
\]

7) **Proof of Lemma 2**

Recall from Lemma 2 that \( U_i \not\subseteq \{ s_j : j \in [i] \} \) and \( U = \{ s_{k_1}, \ldots, s_{k_m} \} \) such that \( k_1 < k_2 < \ldots < k_m \). Let us define \( U' \not\subseteq U \setminus \{ s_{k_1} \} = \{ s_{k_i'}, \ldots, s_{k_{m'}} \} \) where \( k_i' = k_{i+1} \) and \( m' = m - 1 \). We begin with three supporting lemmas.

**Lemma 5.**
\[
U_{k_j} \setminus U' = U_{k_j} \setminus U
\]

**Proof:**
\[
U_{k_j} \setminus U = U_{k_j} \cap (\{ s_{k_1} \} \cup U')^c
= U_{k_j} \cap (\{ s_{k_1} \}^c \cup U'^c)
= U_{k_j} \cap U'^c
\]
The first step follows from the definition of \( U' \) and the last step from recognizing that \( U_{k_j} \subseteq \{ s_{k_1} \}^c \).

**Lemma 6.**
\[
U' = U \setminus U_{k_1}
\]

**Proof:**
\[
U \setminus U_{k_1} = U \cap \{ s_{k_1+1}, s_{k_1+2}, \ldots, s_n \} = \{ s_{k_2}, \ldots, s_{k_{m'}} \} = U'
\]

**Lemma 7.**
\[
U^c = U_{k_1-1} \cup U_{k_1}^c \setminus U
\]

**Proof:**
\[
U_{k_1-1} \cup U_{k_1}^c \setminus U = U_{k_1-1} \cup (U_{k_1}^c \cap U)
= (U_{k_1-1} \cup U_{k_1}^c) \cap (U_{k_1-1} \cup U^c)
= \{ s_{k_1-1} \}^c \cap U^c
= U^c
\]

**Proof of Lemma 2**

**Proof by induction on \(|U|\). Base case:**
If \(|U| = 1\), then \( U = \{ s_{k_1} \} \) and we have that
\[
R(s_{k_1}) = H(X_{U_{k_1}} | X_{U_{k_1}^c}) - H(X_{U_{k_1-1}} | X_{U_{k_1}^c})
= H(X_{U_{k_1-1}} | X_{U_{k_1}}) - H(X_{U_{k_1-1}} | X_{U_{k_1}}^c)
= H(X_{s_{k_1}} | X_{U_{k_1}})
= H(X_{s_{k_1}} | X_{U_{k_1}} \setminus \{ s_{k_1} \})
\]
where the last step follows from the fact that \( U_{k_1}^c = U_{k_1}^c \setminus \{ s_{k_1} \} \).

**Inductive step:** Let us define
\[
U' \equiv U \setminus \{ s_{k_1} \} = \{ s_{k_1'}, \ldots, s_{k_{m'}} \}
\]
where \( k_i' = k_{i+1} \) and \( m' = m - 1 \). We have that
\[
R(U) = R(s_{k_1}) + R(U')
\]
\[
= H(X_{s_{k_1}} | X_{U_{k_1}^c}) + R(U')
\]
\[
= H(X_{s_{k_1}} | X_{U_{k_1}^c}) + H(X_{U'} | X_{U_{k_1}^c} 
\]
\[
+ \sum_{i=1}^{m'-1} I(X_U \setminus U_{k_i}'; X_{U_{k_i+1}^c \setminus U_{k_i}'} ; X_{U_{k_i}^c} \setminus U_{k_i+1}')
\]
\[
= H(X_{s_{k_1}} | X_{U_{k_1}^c}) + H(X_{U'} | X_{U_{k_1}^c} 
\]
\[
+ I(X_{U'} \setminus U_{k_i}'; X_{U_{k_i+1}^c \setminus U_{k_i}'} ; X_{U_{k_i}^c} \setminus U_{k_i+1}')
\]
\[
+ \sum_{i=1}^{m'-1} I(X_{U'} \setminus U_{k_i}'; X_{U_{k_{i+1}^c \setminus U_{k_i}'}} ; X_{U_{k_i}^c} \setminus U_{k_{i+1}'})
\]
\[
= H(X_{s_{k_1}} | X_{U_{k_1}^c}) + H(X_{U'} | X_{U_{k_1}^c} 
\]
\[
+ I(X_{U'} \setminus U_{k_i}'; X_{U_{k_{i+1}^c \setminus U_{k_i}'}} ; X_{U_{k_i}^c} \setminus U_{k_{i+1}'})
\]
\[
+ \sum_{i=1}^{m'-1} I(X_{U'} \setminus U_{k_i}'; X_{U_{k_{i+1}^c \setminus U_{k_i}'}} ; X_{U_{k_i}^c} \setminus U_{k_{i+1}'})
\]
where: (a) follows from the definition of a vertex; (b) follows from the application of the inductive hypothesis; (c) follows from the definition of conditional mutual information; (d) \( U_{k_1}^c \setminus U' = U_{k_2}^c \setminus U' \); (e) \( U' \subseteq U_{k_1}^c \) so partition \( U_{k_1}^c \) into \( U_{k_1}^c \setminus U' \) and \( U' \); (f) follows from the chain rule for conditional entropy; (g) follows from a change of variable for the sum index; (h) follows from expressing the conditional mutual information in terms of the original set, and; (i) follows from moving the first conditional mutual information into the sum.

8) Full Proof of Proposition [\( \text{Proposition 2} \) ]

Proof:

\[
0 \leq R(U) - H(X_U | X_U' ) = H(X_U | X_{U_1}^c \setminus U') - H(X_U | X_{U'} ) + \sum_{j=2}^m I(X_{U\setminus U_{k_{j-1}}} : X_{U_{k_{j-1}} \setminus U_{k_{j-1}}} | X_{U_{k_j}}^c ) = H(U | X_{U_1}^c \setminus U') - H(U | X_{U'} ) + \sum_{j=2}^m I(X_{U\setminus U_{k_{j-1}}} : X_{U_{k_{j-1}} \setminus U_{k_{j-1}}} | X_{U_{k_j}}^c ) = (89)
\]

9) Proof of Proposition [\( \text{Proposition 2} \) ]

Proof: Denote the elements of \( S \) ordered by \( \pi \) as \( t_1, \ldots, t_{|\pi'|}, u_1, \ldots, u_{|\pi'|}, v_1, \ldots, v_{|\pi'|}, w_1, \ldots, w_{|\pi'|}, y_1, \ldots, y_{|\pi'|} \). Then the elements of \( S \) ordered by \( \pi' \) is \( t_1, \ldots, t_{|\pi'|}, v_1, w_1, u_1, \ldots, u_{|\pi'|}, w_1, \ldots, w_{|\pi'|}, y_1, \ldots, y_{|\pi'|} \).

We can show the following

\[
R_\pi(t_i) = H(X_{t_i} | X_{t_{i+1}}, \ldots, X_{t_{|\pi'|}}, X_U, X_V, X_W, X_Y) = H(X_{t_i} | X_{t_{i+1}}, \ldots, X_{t_{|\pi'|}}, X_V, X_U, X_Y) = R_\pi(t_i) \quad (80)
\]

\[
R_\pi(u_i) = H(X_{u_i} | X_{u_{i+1}}, \ldots, X_{u_{|\pi'|}}, X_U, X_V, X_W, X_Y) = H(X_{u_i} | X_{u_{i+1}}, \ldots, X_{u_{|\pi'|}}, X_W, X_Y) = R_\pi(u_i) \quad (81)
\]

\[
R_\pi(v_i) = H(X_{v_i} | X_{v_{i+1}}, \ldots, X_{v_{|\pi'|}}, X_V, X_W, X_Y) = H(X_{v_i} | X_{v_{i+1}}, \ldots, X_{v_{|\pi'|}}, X_W, X_Y) = R_\pi(v_i) \quad (82)
\]

\[
R_\pi(w_i) = H(X_{w_i} | X_{w_{i+1}}, \ldots, X_{w_{|\pi'|}}, X_W, X_Y) = R_\pi(w_i) \quad (83)
\]

\[
R_\pi(y_i) = H(X_{y_i} | X_{y_{i+1}}, \ldots, X_{y_{|\pi'|}} X_Y) = R_\pi(y_i) \quad (84)
\]

10) Proof of Theorem [\( \text{Theorem 16} \) ]

The next lemma establishes that a convex combination of rates can be supported by a convex combination of supporting flows.

**Lemma 8.** Suppose \( R_i \in Q_{\pi SW} \cap P_{\pi} \), and let \( f_i \) be a flow that supports \( R_i \). If \( R_\lambda = \sum_i \lambda_i R_i \) for \( \lambda_i \geq 0 \) and \( \sum \lambda_i = 1 \) then \( f_\lambda = \sum \lambda_i f_i \) is a flow that supports \( R_\lambda \).

**Proof:** Omitted for brevity.

This is a restatement of and proof of Theorem [\( \text{Theorem 16} \) ].

**Theorem 16.** Alternative to Conjecture Let \( f_{R_i}^* \) be a min-cost flow that supports rate \( R_i \). Let \( R = \sum \lambda_i R_i \), the flow \( f = \sum \lambda_i f_{R_i}^* \) is a flow that supports \( R \) of minimum cost if there exists a vectors \( (x^*(a) : a \in A) \) and \( (z^*(v) : v \in V) \) such that for all \( i \)

\[
x^*(a)(f_{R_i}^*(a) - c(a)) = 0 \quad (85a)
\]

\[
(k(a) - x^*(a))(z^*(head(a)) - z^*(tail(a)))f_{R_i}^*(a) = 0 \quad (85b)
\]

for all \( a \in A \).

**Proof:** Having fixed a rate vector \( R_i \), we can solve for the min-cost flow for that rate with following LP

\[
\text{minimize } \sum_{a \in A} k(a)f(a)
\]

subject to \( f(a) \leq c(a) \quad a \in A \)

\[
f(\delta^\text{in}(v)) - f(\delta^\text{out}(v)) = 0 \quad v \in N
\]

\[
f(\delta^\text{in}(v)) - f(\delta^\text{out}(s)) = -R_i(s) \quad s \in S
\]
and its corresponding dual

\[
\begin{align*}
\text{maximize} & \quad \sum_{a \in A} c(a)x(a) - \sum_{s \in S} R_i(s)z(s) \\
\text{subject to} & \quad x(a) + z(\text{head}(a)) - z(\text{tail}(a)) \leq k(a) \quad a \in A. \\
& \quad f \in \mathcal{F}, \quad f(a) \geq 0 \quad a \in A \\
& \quad \text{(87)}
\end{align*}
\]

If \( R_i \) is a feasible rate vector, then there exists a min-cost flow \( f_{R_i}^* \) for this \( R_i \) and therefore optimal dual variables \( (x_{R_i}^*, z_{R_i}^*) \). Observe that the set of feasible dual variables does not depend on the rates \( R_i \), only on the edge costs \( k \). By assumption \( x_{R_i}^* = x^* \) and \( z_{R_i}^* = z^* \) for all \( i \) and therefore \( (x^*, z^*) \) is dual feasible for \( R \). We have that by Lemma 3 that \( f \) is primal feasible. Checking the complimentary slackness conditions for \( f \), \( x^* \), and \( z^* \), we have

\[
\begin{align*}
x^*(f(a) - c(a)) &= x^*(a)\left(\sum_i \lambda_i f_{R_i}^*(a) - c(a)\right) \\
&= \sum_i \lambda_i (x^*(a)(f_{R_i}^*(a) - c(a))) \\
&= 0
\end{align*}
\]

and similarly

\[
(k(a) - x^*(a) - (z^*(\text{head}(a)) - z^*(\text{tail}(a))))f_{R_i}^*(a) = 0.
\]

We conclude that \( f \) is primal optimal and \( x^*, z^* \) are dual optimal solutions for a min-cost flow that supports \( R \). ■

11) Proof of Theorem 10
Proof: Define \( \mu(v) \triangleq \min_p k(P) \) be the value of a min-cost \( v-t \) path in the network and let \( v \to t \) indicate a \( v-t \) path. Let \( \hat{x}(a) = 0 \) for all \( a \in A \) and \( \hat{z} = -\mu(v) \) for all \( v \in V \setminus \{t\} \). At \( \hat{x}, \hat{z} \), the constraints of (35) are equivalent to

\[
\mu(\text{head}(a)) + k(a) \geq \mu(\text{tail}(a)).
\]

Observe that \( \text{tail}(a) \to \text{head}(a) \to t \) is a directed tail-(a) - t path of cost \( \mu(\text{head}(a)) + k(a) \) and therefore \( \hat{x}, \hat{z} \) is dual feasible. Furthermore, for every \( u \in V \setminus \{t\} \), there exists \( v \in V \) such that \( (u, v) \in A \) and \( \mu(u) = \mu(v) + k((u, v)) \). This means that there are at least \(|A| + |V| - 1\) active constraints at \( \hat{x}, \hat{z} \) and it is a vertex. In fact, for a given \( v \in V \) all \( v-t \) paths have the same cost, all constraints are active and \( \hat{x}, \hat{z} \) is the only vertex of the dual feasible set. The dual feasible set is identical for all choices of source rates \( R \) and therefore the optimal solution is give by \( x^* = \hat{x} \) and \( z^* = \hat{z} \). ■

12) Proof of Theorem 12
Proof: Ordering the elements of \( S \) according to the permutation \( \pi \) induces a nested family of subsets \( U_i \triangleq \{s_j : j \in [i]\} \). We construct a dual feasible \( y \) by setting \( y_U = 0 \) for \( U \) not in the nested family and

\[
y_U = \begin{cases} 
\tilde{h}(s_i) - \tilde{h}(s_{i+1}) & i \in [n-1] \\
\tilde{h}(s_i) & i = n.
\end{cases}
\]

We construct a dual feasible \( x \) from (37). Having primal feasible \( (f_{R_i}^*, R_i) \) and dual feasible \( (x, y, z) \), optimality follows from complimentary slackness. ■

13) Proof of Theorem 14
Proof: The condition (51) implies \( B_{\pi(t)} \subseteq \mathcal{P}_t \) for all \( t \in T \), which means that for any vertex of \( Q_{\pi(t)} \) there exists a supporting virtual flow \( f^{(t)} \). If on the other hand (51) does not hold, this implies there exists a sink \( t \in T \) and a vertex of \( Q_{\pi(t)} \) for which no supporting flow \( f^{(t)} \) exists. ■

14) Proof of Theorem 13
Proof: Denote an optimal solution to (46) as \( (f^*, p^*, R^*) \). The optimal value of a min-cost flow for the single sink \( t \) is given by

\[
\sum_{a \in A} k(a)f^{(t)}(a) \geq \sum_{a \in A} k(a)p(a) \geq \sum_{a \in A} k(a)f^{(t)(a)}
\]

which follows from the constraints of (46). Note that the virtual flow \( f^{(t)(a)} \) is a feasible solution to the single sink problem for sink \( t \), contradicting the assumption of \( f^{(t)} \) as an optimal solution to the single sink problem for \( t \). Since \( \sum_{a \in A} k(a)f^{(t)}(a) \) is a lower bound for every \( t \in T \), it must be true for

\[
\max_{t \in T} \sum_{a \in A} k(a)f^{(t)}(a).
\]

To produce an upper bound for the optimal value of (46), we form a feasible solution from \( \{ (f^{(t)}, R^{(t)}): t \in T \} \) the set of optimal solution to single-sink problems:

\[
f^{(t)}(a) = f^*(a) \quad \forall a \in A, t \in T
\]

\[
R^{(t)}(s) = R^*(s) \quad \forall s \in S, t \in T
\]

\[
p(a) = \max_t f^{(t)}(a).
\]

Finally, the cost of this feasible solution is

\[
\sum_{a \in A} k(a) \max_{t \in T} f^{(t)}(a).
\]
