Abstract—Male rats were given daily injections of 200 μg/kg l-thyroxine, s.c., for a period of 10 days. Monoamine oxidase (MAO) activities in the heart, lung and liver mitochondria decreased rapidly to about 50% those of the control rats with 5-HT and β-phenylethylamine (β-PEA) as substrates on the first day. After that, heart MAO activity increased gradually and exceeded the control value after 10 days with 5-HT as the substrate. The level of liver MAO activity was maintained at about 50–70% during the same period of administration with 5-HT as the substrate. The thyroxine treated rats showed no marked change in brain MAO activity. In vitro, l-thyroxine and its metabolites had no discriminative actions on MAO activities in these organs of rats. The heart, lung and liver MAO have unaltered Km values for 5-HT and β-PEA, but decreases in the Vmax for both substrates were observed between the control and l-thyroxine-treated rats. Addition of the brain, heart and liver cytosol fractions from l-thyroxine treated rats caused MAO activities of heart mitochondria to decrease with 5-HT as a substrate and caused them to increase with β-PEA as a substrate. MAO activities in liver also were inhibited by adding all the cytosols when β-PEA was the substrate, but on the contrary, lung MAO activities were increased when 5-HT was the substrate. These results indicate the possible presence of multiple modulators of MAO in the cytosol fractions of l-thyroxine treated rats.

It is well-known that one of the important actions of thyroid hormones is the regulation of protein synthesis, which occurs through a number of changes in enzyme activity as observed by the administration of thyroid hormones or by its deficiency. While many investigators (1–5) have indicated a possible relationship between the thyroid hormone and the catecholamines from the finding that the thyroid hormone alters the activity of an enzyme which metabolizes these catecholamines, the significance of these alterations is not well established.

Since Zile and Lardy (6) produced a decrease in rat liver monoamine oxidase (MAO) by feeding desiccated thyroid to rats, several investigators (7–9) have reported the same results using the ingestion or administration of thyroxine and thyromimetic compounds, while there was an increase in MAO activity of the heart following prolonged administration of these thyromimetic agents (8, 10). In contrast, there have been reports which show an increase of hepatic MAO activity by in thyroid-fed rats (11) and no measurable change in myocardial MAO activity following administration of thyromimetic compounds (12). However, these discrepancies in the measurements of MAO activity depend on the sex and age of the animals used (7, 10, 13, 14).

In this paper, we have investigated further details of the mechanism of the effects of l-thyroxine administration on MAO activity in rat brain, heart, lung and liver mitochondria. In addition, we also have determined whether modulators of MAO are present in the cytosol of each of the rat organs during thyroid hormone treatment.

Materials and Methods

Male Wistar rats (80–100 g) were used in
these experiments. They were housed in temperature-controlled animal quarters and on a circadian cycle of 12 hr light and 12 hr dark, and the animals were fed ad lib with diet and water. The rats were administered 200 μg/kg l-thyroxine (dissolved in saline), s.c., once daily for 10 days. Control rats were given the vehicle only. The rats were killed by decapitation at 24 hr after the last dose as indicated in the figure, and their heart, lung and liver were quickly removed and homogenized in 10 volumes of 0.25 M sucrose (previously adjusted to pH 7.2 with 0.5 M NaHCO₃). The mitochondrial fractions were prepared by the differential centrifugation method as described earlier (15). The mitochondria were washed twice by resuspension in 0.25 M sucrose solution and used as the enzyme preparation. Rat brains were homogenized in 10 volumes of 0.32 M sucrose, pH 7.2, and the mitochondrial fraction was prepared by differential centrifugation. The mitochondria were washed twice by resuspension in 0.32 M sucrose solution and used as the enzyme preparation. Rat brain, heart, lung and liver supernatant (cytosol), obtained by centrifugation of each homogenate at 100,000xg for 60 min, were used as the sources of MAO modulators. All operations were carried out at 4°C.

MAO activity: MAO activity was measured using labelled substrates as described earlier (16). The incubation medium contained a suitable amount of the enzyme preparation (25-100 μg protein) to give a linear reaction for at least 40 min in a total volume of 225 μl of potassium phosphate buffer, pH 7.2. The reaction was started by adding 25 μl of labelled substrate, and incubation was carried out for 20 min at 37°C. Then, the reaction was stopped by adding 2 N HCl. With 14C-serotonin (5-HT) as the substrate, the reaction product was extracted with ether; with 14C-β-phenylethylamine (β-PEA) as the substrate, the product was extracted with toluene. Samples of the extract were mixed with scintillation liquid, and their radioactivities were measured with a Packard-Tricarb Liquid Scintillation Spectrometer. Enzyme activity was expressed as nmole of product formed/min/mg of protein. Substrate concentrations used were 200 μM 5-HT and 50 μM β-PEA as the final concentration.

In investigating the effect of l-thyroxine and its metabolites on MAO activity in vitro, the enzymes were preincubated for 30 min at 37°C with these reagents at the concentration 10⁻³ M to 10⁻¹ M before the addition of the substrates.

In studies utilizing MAO inhibitors, the enzyme preparations were preincubated for 1 hr at 37°C in small test tubes containing 0.1 M potassium phosphate buffer, pH 7.2, and the desired concentration of inhibitors (10⁻⁶ M to 10⁻¹¹ M). After the addition of substrates, the remaining MAO activity was measured. (-) Deprenyl for B-form MAO and clorgyline for A-form MAO were used as MAO inhibitors.

Protein concentrations of the preparations were measured by the method of Lowry et al. (17) with bovine serum albumin as the standard.

Results

1. Changes of MAO activity in mitochondria of several organs of rats injected with 200 μg/kg l-thyroxine, s.c., for 10 days: The MAO activities in rat heart, brain, lung and liver mitochondria were measured with 5-HT and β-PEA as substrates after administration of 200 μg/kg l-thyroxine, s.c. As shown in Fig. 1, MAO activities of each of the enzyme preparations were very markedly inhibited on the first day after administration of l-thyroxine except in the case of brain mitochondria for which only a slight inhibition of MAO activity was observed with 5-HT and β-PEA as substrates. In the case of heart mitochondria, MAO activity began to increase gradually on the third day after administration; and at 10 days, it was almost restored to the control value with 5-HT as the substrate and exceeded that of the control with β-PEA as the substrate.
Effects of Thyroxine on MAO Activity

Fig. 1. Changes of MAO activity in mitochondria of rats injected with 200 μg/kg /-thyroxine, s.c., for 10 days. MAO activity is measured using labelled substrates as described earlier. Specific activity is expressed as nmoles of products formed/min/mg of protein. The mean±S.E. control values for MAO activity were 1.02±0.12 and 0.73±0.02 in the heart, 1.75±0.05 and 2.23±0.03 in the brain, 0.86±0.09 and 7.87±0.02 in the lung, and 3.25±0.09 and 13.88±0.13 in the liver with 5-HT and β-PEA as substrates, respectively. Each point represents the mean percentages (±S.E.) of the activity of the enzyme in five rats. ●—● 5-HT, ○——○ β-PEA. *P<0.05.

control value at 10 days after administration of /-thyroxine. When liver was used as the enzyme preparation, MAO activities were about 60% and 40% of the control value on the first day with β-PEA and 5-HT as substrates, respectively. After that, the MAO activities increased temporarily and finally were maintained at about 70% and 50%, respectively, from the 7th to the 10th days.

2. Km and Vmax values of MAO in the mitochondria of rats: In order to investigate the relationship between the difference of MAO activity on the first day and the 10th day after administration of /-thyroxine, the enzymic properties of MAO in each enzyme preparation were compared. The Km and Vmax values for the control and mitochondrial preparations of rats by administration of /-thyroxine on the first day and on the 10th day were determined from Lineweaver-Burk double reciprocal plots of values obtained from graphic representation of kinetic data. As shown in Table 1, when the heart, lung and liver mitochondrial preparations of rats injected with /-thyroxine for one day were used, Vmax values decreased significantly compared with that of the control, although the Km values with β-PEA and 5-HT as substrates were almost identical. When the mitochondrial preparations from rats given the /-thyroxine for 10 days were used, a significant decrease of Vmax values in the lung and liver with β-PEA and a significant increase of Vmax value in heart were observed, although the Km values with 5-HT and β-PEA as substrates were also almost identical.

3. Effects of /-thyroxine and its mitochondrial MAO from rat brain, heart, lung and liver: To investigate whether the decrease of MAO activity in thyroxine-treated rats is due to the direct inhibiting action by /-thyroxine and its metabolites, the effects of /-thyroxine and several of its metabolites were tested in vitro. /-Thyroxine, 3,3′,5-triiodothyronine, 3,5-diiodotyrosine, 3,5-diiodothyronine and 3-iodotyrosine (final concentration of 10^-4 M) were added to the incubation mixture containing fresh brain, heart, lung and liver mitochondria from normal rats. No significant changes in the rate of 5-HT and β-PEA ox-

$K_m$ and $V_{max}$ values are calculated from Lineweaver-Burk plots with six substrates concentrations. Results are expressed as values of the mean±S.E. of assays in five rats. MAO activity was assayed radiometrically at 37°C for 20 min with 5-HT and β-PEA as substrates. Enzyme: mitochondrial preparations in brain, heart, lung and liver from rats administered l-thyroxine on the first day and 10th days. *P<0.05. $K_m$: μM, $V_{max}$: nmoles/min/mg of protein.

Each enzyme preparation was preincubated for 1 hr at 37°C in a small test tube containing 0.1 M potassium phosphate buffer, pH 7.2, and the desired concentrations of inhibitors, clorgyline (for A-form MAO) and deprenyl (for B-form MAO). After the addition of substrates (5-HT for A-form MAO and β-PEA for B-form MAO), the remaining MAO activity was measured. The $p_{150}$ values were determined from the graphic representation of the pl curves obtained from each of the MAO activity values inhibited by several concentration of inhibitors. Mitochondria of control rats and those of rats treated with l-thyroxine for one day and 10 days were used as enzyme preparations. Each value represents the mean±S.E. of five rats. *P<0.05.
Effects of Thyroxine on MAO Activity were observed with or without preincubation with these reagents and enzymes (data not shown).

4. $p_{50}$ values of clorgyline and deprenyl on MAO in mitochondria of rats injected with $\beta$-thyroxine: In order to determine whether the loss of enzyme activity is due to a decrease in the molecular amount of MAO, $p_{50}$ values on rat mitochondrial MAO were compared in the inhibition experiment with clorgyline (for A-form MAO) or deprenyl (for B-form MAO) using 5-HT (for A-form MAO) and $\beta$-PEA (for B-form MAO) as substrates, respectively. Clorgyline and deprenyl inhibit MAO irreversibly at the ratio of 1:1, i.e., the amount of enzyme inhibited was equal to the amount of inhibitor added on a molar basis. If the loss of enzymic activity in thyroxine-treated rats was due to a loss of the amount of enzyme molecules, $p_{50}$ values of clorgyline and deprenyl should be shifted to the side of lower concentrations of inhibitors. As shown in Table 2, a significant decrease in the $p_{50}$ value was observed using the thyroxine-treated mitochondrial preparations in heart and liver on the first day and on the 10th day using 5-HT and $\beta$-PEA as substrates. On the contrary, a significant increase in the $p_{50}$ values were observed using the thyroxine-treated mitochondrial preparations in the lung.

5. Effects of each of the cytosol fractions on MAO activity in mitochondria of several organs in rats: As can be seen in Table 3, the possibility of a modulator being present was tested by adding the brain, heart, lung and liver supernatant (cytosol) obtained by centrifugation at 100,000 x g of the homogenate from rats treated with $\beta$-thyroxine treatment for 10 days to each of the mitochondrial preparations from normal animals. MAO activities of the brain were inhibited by adding the brain and heart cytosol when $\beta$-PEA served as the substrate. MAO activity in liver mitochondria was also inhibited by adding brain, heart, lung or liver cytosol when $\beta$-PEA was the substrate. When heart mitochondria was used as the enzyme source, heart and liver cytosols inhibited MAO activity with 5-HT as the substrate; and on the contrary, brain, heart and liver cytosols activated this activity with $\beta$-PEA as the substrate. The opposite results were obtained when lung mitochondria was used as the enzyme source, i.e., a significant increase of lung MAO with 5-HT as the substrate was observed by adding all the cytosols. Furthermore, when each mitochondria was incubated with increasing amounts of cytosol, a linear increase in the activation or inhibition of the MAO activity toward 5-HT and $\beta$-PEA was observed (data not shown).

**Discussion**

There are many reports on the effects of thyromimetic compounds on MAO activity; some have indicated that the hepatic MAO activity was decreased (6–9), while the

After preincubation at 37°C for 20 min with mitochondrial preparations by adding the each of cytosol fractions, MAO activity was determined with 5-HT and $\beta$-PEA as substrates at 37°C for 20 min. The results are the means of triplicate assays. Values are percentages of the control MAO activity without cytosol fractions. The fact that the cytosol MAO activity added was less than 1% that of the mitochondria indicates that the increase was not due to the additive activity of the MAO present in the cytosol. *Normal fresh mitochondrial preparations. †Supernatant fraction (cytosol) obtained by 100,000 x g centrifugation of the homogenate from rats treated with $\beta$-thyroxine for 10 days. ‡P<0.05.
cardiac MAO activity was increased in hyper-thyroid rats or by administration of thyro-mimetic compounds (10, 13, 14). However, in this study, it was confirmed that MAO activity in heart, lung and liver mitochondria decreased rapidly to about 50% that of the control values on the first days; and after that, heart MAO activity increased gradually and completely restored to the control value after 10 days, although it has been reported that there is a continuous increase of cardiac MAO activity with age and weight in male rats up to 16 weeks of age (10, 18). However, \(L\)-thyroxine administration caused the heart MAO activity with 5-HT as the substrate to exceed that of the control value of the 10th day, while the level of the liver MAO activity was maintained at about 50 to 70% during the period of administration of \(L\)-thyroxine when 5-HT was the substrate. When \(\beta\)-PEA was used as the substrate, MAO activity increased temporarily; and after that it was about 80% that of the control. In order to investigate the decrease of MAO activity on the first day or the 10th day after administration of \(L\)-thyroxine, the enzymic properties of MAO in each enzyme preparation were compared. The \(V_{\text{max}}\) values in thyroxine-treated rats decreased significantly compared with that of the control, although the \(K_m\) values were almost identical except for the mitochondrial preparation from rat brain. In addition, no significant changes in the rate of 5-HT and \(\beta\)-PEA oxidation were observed with or without preincubation of \(L\)-thyroxine and its metabolites with the enzyme preparations in vitro. Therefore, these decreases of MAO activity were not due to the alteration of the MAO molecule, as judged from the constancy of the \(K_m\) value for 5-HT and \(\beta\)-PEA with control and thyroxine-treated enzyme preparations. Moreover, the decrease of MAO activity in thyroxine-treated rats did not depend on the direct inhibition by the \(L\)-thyroxine or several its metabolites and by the binding of MAO enzymes. So, in order to also investigate the decrease of \(V_{\text{max}}\) values after administration of \(L\)-thyroxine, the molecular amounts of MAO were examined by titration experiment with clorgyline and deprenyl. Significant decrease of \(p_{150}\) values in the heart and liver and increase in the lung were observed. The reason for the discrepancies in these data is not clear. It may be related to the precision of the titration method. Sterlings and Milch (19) have shown that the thyroid hormone binds to the intranuclear chromatin protein associated with active DNA, where it is believed to stimulate transcription. Therefore, it seems that thyroid hormones may regulate the biosynthesis of this enzyme or control other enzyme that govern the activity of MAO in these tissues. However, the mechanism of the marked MAO inhibition during the first day by the administration of \(L\)-thyroxine is not clear at this time and cannot be explained until further experiments are done to determine the relationship between other enzymes and hormones in these organs.

Several reports have been written on the possible existence of A- and B-form MAO in various mammalian tissues, showing that the relative activities of the two forms vary widely between the various organs (20) and between different animal species (21, 22). In addition, activities vary with the conditions of assay of MAO activity (23–25) or the administration of some drugs (26, 27). A-form MAO preferentially deaminates 5-HT (28), whereas B-form MAO deaminates \(\beta\)-PEA (29). In this paper, the possibility that the two forms of MAO may respond differently to thyroid hormones was investigated. When 5-HT was used as the substrate, thyroxine-treated rats showed an increase in the heart MAO activity and a decrease in liver MAO activity. However, when \(\beta\)-PEA was used as the substrate, both lung and liver MAO activities decreased. Therefore, it supports the conjecture that thyroid hormones may exert discriminative action on the different forms of MAO.

Recently, there are many reports on the possible presence of MAO modulators in the soluble fraction of homogenate (14, 30, 31), in plasma (32–34) and in urine (35–37), and they indicated that these modulators could play one of several roles in relation to MAO activity and behavior. Ichikawa et al. (38) have reported that endogenous MAO inhibitors are induced in the soluble fractions of rat heart by thyroid hormone administration. In the present study, our results also indicated
evidence for the possible existence of the multiple modulators of MAO being present in the cytosol fractions of various organs of /-thyroxine-treated rats and that these modulators could play the role of activators or inhibitors to MAO depending on the substrates or the organs used. Moreover, the changes of MAO activity during the administration of /-thyroxine may due to the production of these modulators in the soluble fractions. It is likely that there are binding sites of these modulators on the outer mitochondrial membranes, but these must be in a different position from the MAO molecule. The binding of modulators to the outer membranes may bring about a structural or functional change in the outer membrane (19, 39).

In this paper, we have confirmed the possible presence of activators in the soluble fractions when crude brain heart, lung and liver homogenates have been used as preparations in the treatment with /-thyroxine, although these experimental results failed to reveal any rule regarding the activating or inhibiting action by these modulators to MAO. We are now using the liver soluble fraction of /-thyroxine-treated rats further studies on purification and identification and for investigating some properties of substances in this fraction.
