Abstract

Posttransplantation diabetes mellitus (PTDM) is a frequent complication in immunosuppressive therapy. To better understand the molecular events associated with PTDM we investigated the effect of cyclosporine on expression and activity of hepatic nuclear factor (HNF)1alpha and 4alpha and on genes coding for glucose metabolism in cultures of the rat insulinoma cell line INS-1E, the human epithelial cell line Caco-2 and with Zucker diabetic fatty (ZDF) rats. In the pancreas of untreated but diabetic animals expression of HNF4alpha, insulin1, insulin2 and of phosphoenolpyruvate carboxykinase was significantly repressed. Furthermore, cyclosporine treatment of the insulinoma-1E cell line resulted in remarkable reduction in HNF4alpha protein and INS1 as well as INS2 gene expression, while transcript expression of HNF4alpha, apolipoprotein C2, glycerokinase, pyruvatekinase and aldolase B was repressed in treated Caco-2 cells. Furthermore, with nuclear extracts of cyclosporine treated cell lines protein expression and DNA binding activity of hepatic nuclear factors was significantly repressed. As cyclosporine inhibits the calcineurin dependent dephosphorylation of nuclear factor of activated T-cells (NFAT) we also searched for binding sites for NFAT in the pancreas specific P2 promoter of HNF4alpha. Notably, we observed repressed NFAT binding to a novel DNA binding site in the P2 promoter of HNF4alpha. Thus, cyclosporine caused inhibition of DNA binding of two important regulators for insulin signaling, i.e. NFAT and HNF4alpha. We further investigated HNF4alpha transcript expression and observed >200-fold differences in abundance in n=14 patients. Such variability in expression might help to identify individuals at risk for developing PTDM. We propose cyclosporine to repress HNF4alpha gene and protein expression, DNA-binding to targeted promoters and subsequent regulation of genes coding for glucose metabolism and of pancreatic beta-cell function.

Introduction

In organ transplantation there is a need to suppress an immune response against the grafted organ. Immunosuppressive therapies with calcineurin inhibitors result, however, in unwanted secondary effects. This includes risk of infections of all types, lymphomas and other malignancies [1,2]. Posttransplantation diabetes mellitus (PTDM) is a further complication with an incidence of approximately 8–10% for cyclosporine and 16–18% for tacrolimus across renal, liver, heart and lung transplant patients [3,4]. Noteworthy, the DIRECT study reports a 36% incidence of impaired glucose metabolism and a 14% incidence of PTDM with either cyclosporine or tacrolimus [5]. Indeed, cyclosporine caused morphologic and functional alterations of pancreatic beta-cells with subsequent hyperglycemia and hypoinsulinoma in diverse animal studies [6–11]. Based on their mode of action cyclosporine and tacrolimus repress interleukin-2, thereby suppressing the early cellular response of T-lymphocytes to an antigenic stimuli. As of today the causes for the diabeticogenic potential of calcineurin inhibitors remain uncertain. To better understand the molecular events associated with PTDM we investigated expression and activity of hepatic nuclear factor 1α (HNF1α) and 4α (HNF4α). Notably, dysfunction of these transcription factors have been associated with diabetes mellitus. For instance, the early onset of type II diabetes referred to as MODY (maturity onset diabetes of the young) was mapped to mutations within the HNF1α (MODY3) and HNF4α (MODY1) gene [12]. Moreover, linkage analysis in combination with fine-mapping for susceptibility to multifactorial late-onset type 2 diabetes has identified predisposing variants of HNF4α and HNF1α in a growing number of studies [13–15]. The HNF4α-dependent transcription of HNF1α is required for normal β-cell function [16], but there is also a feedback loop of HNF4α and HNF1α to maintain tissue specific metabolic function [16–18]. Additionally, in conditional HNF4α knockout mice β-cell function was impaired upon glucose-stimulated insulin secretion [19–21] whereas HNF1α knockout mice develop diabetes [22].

Taken collectively, HNF1α and HNF4α regulate various members of the glucose-dependent insulin secretory pathways [19–28] and might therefore provide a molecular rational for calcineurin inhibitor induced diabetes.
Results and Discussion

Initially, we investigated expression of HNF4α in the pancreas of Zucker diabetic fatty (ZDF) rats. This is an established disease model for type 2 diabetes. We observed reduced expression of HNF4α and of genes regulated by this factor in the glucose metabolic pathway, notably phosphoenolpyruvate carboxykinase 1 (PCK1), insulin1 (INS1) and insulin2 (INS2) (Table 1). Furthermore, HNF4α and HNF1α was significantly reduced in the liver of these animals (Table 1). In the past HNF4α was shown to regulate INS1 [29]. As rodents express two isoforms of insulin (INS1 and INS2) [30] both genes were investigated, but the physiological role of INS2 is not clear as yet [30]. By use of advanced bioinformatics we identified a new HNF4α binding site in the promoter of the INS2 gene at position -245 to -232 upstream of the start site of transcription [see Material and Methods for sequence information and electrophoretic mobility shift (EMSA) assay in Fig. 1D]. Loss of HNF4α DNA-binding to targeted promoters resulted in reduced expression of genes coding for glucose transport and metabolism and of insulin secretion from pancreatic β-cells [28]. Furthermore, in conditional HNF1α knockout mice β-cell function was impaired upon glucose-stimulated insulin secretion [19–21]. Conversely, in HNF1α overexpressing beta cell lines increased transcript expression of insulin, glucose transporter 2, L-pyruvate kinase, and aldolase B was observed [26,27] whereas HNF1α knockout mice developed diabetes [22].

To further probe for HNF4α and HNF1α function we cultured the human intestinal cell line Caco-2. This cell line enables mechanistic studies with HNF4α protein expression being comparable to its expression levels in the liver [31]. In cell culture experiments we analyzed the effect of cyclosporine on HNF4α and HNF1α expression and activity. HNF4α gene and protein expression (Table 2, Fig 1A) as well as HNF1α protein expression (Fig 1B) was significantly repressed after treatment of Caco-2 cells with 25 μM (30 μg/ml) cyclosporine for 72 h, but HNF1α gene expression remained unchanged (Table 2). For comparison actin western blotting was used as housekeeping protein (Fig 1C).

Additionally, we investigated expression of genes coding for glucose metabolism, i.e. apolipoprotein C2 (ApoC2), alcohol dehydrogenase 2 (ALDH2), phosphoenolpyruvate carboxykinase 1 (PCK1), glycerol kinase (Gk), pyruvate kinase (PKLR) and aldolase B (ALDOB), and found ApoC2, Gk, PKLR and ALDOB transcripts to be significantly repressed (Table 2). We further studied the ability of HNF4α to bind to promoter sequences of HNF1α, ApoC2, Gk, PKLR, ALDOB, and IN2 by EMSA supershift assays. As shown in Fig. 1D we observed strong binding of nuclear extracts of untreated cell cultures to all cognate recognition sites. Addition of a specific HNF4α antibody shifted the band, therefore providing clear evidence for the specificity of the assay. Strikingly, cyclosporine reduced binding of HNF4α to all EMSA probes employed to approximately 20% when compared with untreated cell cultures (Fig 1D, 1E). Binding activity of HNF1α to its recognition site in the pancreas specific P2 promoter of HNF4α was reduced as well (Fig. 2A, 2B), but treatment with equimolar concentrations of the calcineurin inhibitor tacrolimus did not influence HNF4α gene expression (Table 3).

To further confirm cyclosporine mediated dysregulation of HNF4α we analyzed different rat and mouse beta cell lines, i.e. INS-1E, RINm5F and MIN6 cells, for its HNF4α expression. INS-1E cells express HNF4α more abundantly and therefore were used for subsequent experiments (Table 4). As INS-1E cells are much more sensitive to the cyclosporine induced toxicity effects than Caco-2 cells, cell viability was tested at different cyclosporine concentrations. Treatment of INS-1E cells with 8.3 μM (10 μg/ml) cyclosporine (one third of the concentration used for Caco-2 cells) resulted in a 55% viability (Fig. 3A). In western blotting experiments actin served as a housekeeping protein, which we found to be constantly expressed (Fig. 3B). HNF4α protein expression of INS-1E cells is much lower than in liver [32]. In nuclear protein extracts HNF4α expression was below the limit of detection but its gene expression was unchanged (Table 5). Nonetheless, HNF4α DNA binding activity could be assayed for in EMSA supershift assays and was significantly reduced to 58% after treatment with 8.3 μM (10 μg/ml) cyclosporine (Fig. 3C, 3D). It is of considerable importance that the gene expression of the HNF4α target genes insulin1 (INS1) and insulin2 (INS2) was significantly repressed (Table 5).

Taken collectively, HNF4α and HNF1α expression and DNA-binding activity was repressed after cyclosporine treatment as was transcription of genes in the glucose and insulin signaling pathways targeted by HNF4α and HNF1α. Our study is the first report to determine a direct connection between cyclosporine treatment and activity of hepatic nuclear factors and our findings provide a molecular rational for PTDM observed in transplant patients. We suggest individual differences in the HNF4α gene and protein expression amongst patients to be of critical importance for the diabeticogenic potential of cyclosporine. Indeed, on average 1/10 of cyclosporine treated patients develop PTDM. Consequently, repression of HNF4α by cyclosporine depends on the abundance of HNF4α protein. In Fig. 4 HNF4α gene expression in the liver of 14 patients was plotted; the data are scattered over a wide range. Likely, patients with low HNF4α and HNF1α protein would be at higher risk of developing cyclosporine induced PTDM. Specifically, cyclosporine binds to calcineurin and inhibits Ca2+-dependent serine / threonine phosphatase activity [33]. Normally this phosphatase dephosphorylates nuclear factor of activated T-cells (NFAT), which moves from the cytoplasm to the nucleus to activate gene expression.

### Table 1. Regulation of HNF4α and its target genes in Zucker diabetic fatty (ZDF) rats.

| Gene   | Organ        | Treatment | Mean ± SD | % of the control | p-value |
|--------|--------------|-----------|-----------|------------------|---------|
| HNF4α  | Pancreas     | Control   | 0.013 ± 0.002 | ZDF 9 months | 0.0494  |
|        |              | ZDF 9 months | 0.008 ± 0.004 | 61.5          |
| PCK1   | Pancreas     | Control   | 0.857 ± 0.849 | ZDF 9 months | 0.0191  |
|        |              | ZDF 9 months | 0.365 ± 0.541 | 42.6          |
| INS1   | Pancreas     | Control   | 0.146 ± 0.076 | ZDF 9 months | 0.0126  |
|        |              | ZDF 9 months | 0.109 ± 0.217 | 74.5          |
| INS2   | Pancreas     | Control   | 0.960 ± 0.487 | ZDF 9 months | 0.0052  |
|        |              | ZDF 9 months | 0.456 ± 0.871 | 47.5          |
| HNF1α  | Liver        | Control   | 1.379 ± 0.611 | ZDF 14 weeks | 0.0494  |
|        |              | ZDF 14 weeks | 0.835 ± 0.365 | 60.6          |
| HNF4α  | Liver        | Control   | 1.180 ± 0.330 | ZDF 14 weeks | 0.0015  |
|        |              | ZDF 14 weeks | 0.694 ± 0.228 | 58.8          |

Gene expression was measured by real-time qRT-PCR in 14 weeks and 9 months old ZDF rats and lean controls (n = 10 animals, respectively) and was determined relative to expression of cyclophilin, which served as a housekeeping gene. Gene expression in control rats was set to 100 and values for ZDF rats represent transcript abundance relative to control. Non-parametric Mann-Whitney-U-Test was used to compare ZDF and control groups. Results are considered significant at p<0.05 (gene names and p-values in bold). Gene expression of HNF4α in the liver of this cohort of ZDF rats has been previously reported [43].

doi:10.1371/journal.pone.0004662.t001
associate with other proteins, thereby regulating expression of interleukin-2, granulocyte macrophage colony stimulating factor (GM-CSF), TNFα, IFNγ and other interleukins [34,35]. Although inhibition of calcineurin results in immunosuppression, altering activity of NFAT will also impact regulation of INS1 gene transcription. Indeed, this factor is activated by calcineurin in response to increased Ca²⁺-levels [36]. Disruption of the NFAT/insulin pathway may contribute to the diabetogenic effects of cyclosporine as will be discussed below. Notably, Heit et al [37] reported the β-cell specific deletion of calcineurin to result in age-dependent diabetes, while conditional expression of activated NFAT reverted the diabetic phenotype in these mice. Furthermore, expression of genes critical for β-cell endocrine function e.g. HNF4α and HNF1α was increased in mice when NFATc1 was conditionally activated [37]. It is of considerable importance that NFAT cooperates with other transcription factors involved in insulin transcription such as PDX1, NEUROD1 and HNF4α. The evidence for this cooperation stems from chromatin immunoprecipitation assays [37]. The calcineurin/NFAT signaling appears to be essential for the regulation of pancreatic β-cell function; its cooperation with HNF4α could provide a molecular rational for cyclosporine induced PTDM [37]. HNF4α activity differs amongst cell types, in part due to use of alternate promoters. Whilst in hepatocytes the P1 promoter of HNF4α is primarily activated, the P2 promoter is specifically activated in pancreatic β-cells [17,18]. Indeed, P2 is exclusively expressed in INS-1E cells, see Table 6. In the study of Heit et al [37] binding of NFAT to the P1 promoter of HNF4α (NM_008261) was observed. The findings of Heit et al [37] are surprising as for normal β-cell function usage of the P2 promoter of HNF4α would have been expected. Notably, we observed NFAT binding at the human P2 promoter of HNF4α at position ~461 to ~450 upstream of the start site of transcription (see Material and Methods for sequence information). Furthermore, binding of NFAT to the HNF4α P2 promoter was reduced in response to cyclosporine treatment (Fig. 5A, 5B), but expression of members of the NFAT gene family (NFATc1, c2, c3, c4) and of calcineurin itself was unchanged after cyclosporine treatment of Caco-2 cells (Table 2). There is clear evidence for a role of NFAT in glucose/insulin homeostasis [38]. NFAT signaling plays an essential role in the development of diabetes in calcineurin knockout mice [37]. Taken collectively, we report a remarkable repression of HNF4α and HNF1α after cyclosporine treatment and propose cyclosporine to act through a calcineurin/NFAT dependent mechanism on these transcription factors. We further identified a novel NFAT binding site in the human HNF4α P2 promoter and report HNF4α activity and expression of genes of the glucose/insulin signaling pathway to be reduced in the pancreas of ZDF diabetic rats.

In conclusion, cyclosporine repressed HNF4α/HNF1α expression, DNA-binding to targeted promoters and subsequent expression of genes involved in glucose metabolism and pancreatic β-cell function. We propose a molecular mechanism for PTDM based on dysregulation of HNF4α/HNF1α and of NFAT insulin signaling pathway targeted by cyclosporine.

Materials and Methods

Cell culture and cyclosporine treatment

Caco-2 cells, a human intestinal cell line derived from a colon adenocarcinoma, were obtained from and cultivated as recom-
mended by DSMZ (Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH, Braunschweig, Germany). INS-1E cells (rat beta cells derived from insulinomas) were kindly provided by C. Wollheim (University Medical Center, Geneva, Switzerland) [39], MIN6 cells (mouse beta cells transgenic for SV40 large T antigen) were kindly provided by J. Miyazaki (Osaka University Medical School, Japan) [40] and MIN-m5F cells (rat beta cells derived from islet cell tumor) were kindly provided by S. Lenzen (Medical School Hannover, Germany) [41]. Caco-2 cells were daily treated with 25 \( \mu \text{g/mL} \) tacrolimus (Astellas Pharma GmbH, Munich, Germany) (n = 3, respectively) and INS-1E cells with 8.3 \( \mu \text{M} \) (10 \( \mu \text{g/mL} \)) cyclosporine (Sandimmun, Novartis, Nuernberg, Germany) for 72 h. Treatment started at 40-50% confluence. Cell viability was analyzed in triplicate using a MTS cytotoxicity assay according to the manufacturers instructions (#G3582, Promega, Mannheim, Germany).

### Diabetic disease model

Pancreas (animals aged 9 months) and liver (animals aged 14 weeks) of fa/fa obese Zucker diabetic fatty (ZDF) rats and of +/+ lean nondiabetic control rats were kindly provided by W. Linz and H. Ruettten (Sanofi-Aventis, Frankfurt, Germany) [42]. Pancreatic mRNA degrades quickly, i.e. in less than 1 minute after tissue resection, therefore, pancreas was frozen immediately. All rats were male with mean body weight of 398.8 ± 30.2 (obese) and 334.2 ± 19.3 (lean) for 14 weeks aged animals and 403.8 ± 33.7 (obese) and 463.3 ± 30.3 (lean) for 9 months aged animals. Representative phenotype data (e.g. blood glucose, insulin) are provided in Niehof et al [43].

### Isolation of nuclear extracts, western blotting analysis and electrophoretic mobility shift assays

Nuclear extracts were isolated by the method of Dignam et al [44] with minor modifications as detailed previously [31]. Details for western blotting analysis and electrophoretic mobility shift assays were given in Niehof and Borlak, 2005 [31]. Antibodies directed against HNF4a (sc-6556), HNF1\( \alpha \) (sc-6547), and Actin (sc-1616) were purchased from Santa Cruz Biotechnology (Heidelberg, Germany). Nuclear extracts were prepared mainly in triplicate and used as described in the figure legend. The antigen-antibody complexes were visualized using the enhanced chemiluminescence (ECL) detection system (PerkinElmer Life Sciences, Rodgau-Jugensheim, Germany). Light signal detection was done with the CCD camera Imager system Kodak IS 440 CF (Kodak, Biostep GmbH, Jahnsdorf, Germany) and quantification was performed using the Kodak 1D Image analysis software (version 3.5.). The oligonucleotides were purchased from MWG Biotech (Ebersberg/Muenchen, Germany) with the following sequences: AAG GCT GAA GTC CAA AGT TCA GTC CCT TC (HNF1\( \alpha \), NM_000545), TGT CTA GGC CAA AGT CCT

### Table 3. HNF4\( \alpha \) gene expression in Caco-2 cells after tacrolimus treatment.

| Gene   | Treatment | Mean ± SD | p-value |
|--------|-----------|-----------|---------|
| HNF4\( \alpha \) | Control   | 1.373 ± 0.347 |         |
|        | Tacrolimus | 1.166 ± 0.127 | 0.5127  |

Gene expression was measured by real time qRT-PCR in Caco-2 cells 72 h after treatment with 25 \( \mu \text{M} \) (20 \( \mu \text{g/mL} \)) tacrolimus (Astellas Pharma GmbH, Munich, Germany) (n = 3, respectively) and was determined relative to expression of mitATPase6, which served as a housekeeping gene. Non-parametric Mann-Whitney-U-Test was used to compare tacrolimus treated and control groups. Results are considered significant at p<0.05.

doi:10.1371/journal.pone.0004662.t003

### Table 4. HNF4\( \alpha \) gene expression in different beta cell lines.

| Beta cell line | Species | Gene | % Expression |
|----------------|---------|------|--------------|
| INS-1E         | Rat     | HNF4\( \alpha \) | 25.039 ± 7.968 |
| RIN-m5F        | Rat     | HNF4\( \alpha \) | 1.289 ± 0.071  |
| MIN6           | Mouse   | HNF4\( \alpha \) | 0.094 ± 0.026  |

HNF4\( \alpha \) gene expression was measured by real time qRT-PCR in INS-1E, RIN-m5F or MIN6 cells after 6 days in culture (n=3, respectively). Gene expression was determined relative to expression of mitATPase6, which served as a housekeeping gene. Gene expression in untreated liver was set to 100% and values for gene expression in beta cells were calculated relatively.
doi:10.1371/journal.pone.0004662.t004

Figure 2. Cyclosporine inhibits HNF1\( \alpha \) to the P2 promoter of HNF4\( \alpha \). (A) Electrophoretic mobility shift assays with 2.5 \( \mu \)g Caco-2 cell nuclear extract [control or cyclosporine treatment, 25 \( \mu \text{M} \) (30 \( \mu \text{g/mL} \)] for 72 h] and \( ^{32} \text{P} \) labeled oligonucleotides to probe for DNA binding to the HNF1\( \alpha \) binding-site within the HNF4\( \alpha \) P2 promoter (HNF1\( \alpha \) site in HNF4\( \alpha \) P2). In EMSA supershift assays an antibody directed against HNF1\( \alpha \) was added. Control and treated probes were run on same gels. (B) Dried EMSA gels were analyzed with a Molecular Imager (BioRad) using the Quantity One software (BioRad). HNF1\( \alpha \) binding of control extracts was set to 100% and inhibition of binding after treatment with cyclosporine [25 \( \mu \text{M} \) (30 \( \mu \text{g/mL} \)] for 72 h] was quantified.
GGC CA (ApoC2, apolipoprotein C2, NM_000483), GCT GCC TGC CAA AGG GCA GTA CT (GK, glycerol kinase, NM_203391), AGA TGA GGG CAG AGA GCA GGC CG (PKLR, pyruvate kinase, NM_000298), ACA AAA GTA CAA AGG TTA AAA GA (ALDOB, aldolase B, NM_000035), GAC AAA CAG CAA AGT CCA GGG GT (INS2, insulin 2, NM_019130), GAC TGG TTA CTC TTT AAC GTA TC (HNF1-site in HNF4α, NM_001030004), and CCC TCC TTT TTT CCT CTG CCC CT [NFAT-site (nuclear factor of activated T-cells) in HNF4α, NM_001030004] and were 32P-labeled. Super shift assays were done with HNF4α specific antibody (sc-6556x), HNF1α specific antibody (sc-6547x), and NFAT specific antibody (sc-1149x), all were purchased from Santa Cruz Biotechnology, Heidelberg, Germany and once again details are given in [31].

RT-PCR and real-time semi-quantitative PCR

Total RNA was isolated using the nucleospin RNA Isolation Kit (Macherey-Nagel) according to the manufacturers recommendations. 4 μg total RNA from each sample was used for reverse transcription (OmniScript Reverse Transcriptase, Qiagen, Hilden, Germany). Gene expression was measured by real-time qRT-PCR in INS-1E cells 72 h after treatment with 8.3 μM (10 μg/ml) cyclosporine (n = 3, respectively) and was determined relative to expression of mitATPase6, which served as a housekeeping gene. Gene expression in untreated INS-1E cells was set to 100 and values for cyclosporine treatment represent transcript abundance relative to control. Non-parametric Mann-Whitney-U-Test was used to compare cyclosporine treated and control groups. Results are considered significant at p < 0.05 (gene names and p-values in bold).

Table 5. Regulation of gene expression in INS-1E cells after cyclosporine treatment.

| Gene | Treatment | Mean ± SD | % of the control | p-value |
|------|-----------|-----------|-----------------|---------|
| HNF4α | Control    | 0.849 ± 0.308 | 100  |         |
|       | Cyclosporine | 0.984 ± 0.066 | 117  | 0.5127 |
| INS1  | Control    | 0.128 ± 0.003 | 100  |         |
|       | Cyclosporine | 0.087 ± 0.004 | 76.0 | 0.0495 |
| INS2  | Control    | 1.076 ± 0.237 | 100  |         |
|       | Cyclosporine | 0.335 ± 0.039 | 31.3 | 0.0495 |

Gene expression was measured by real-time qRT-PCR in INS-1E cells 72 h after treatment with 8.3 μM (10 μg/ml) cyclosporine (n = 3, respectively) and was determined relative to expression of mitATPase6, which served as a housekeeping gene. Gene expression in untreated INS-1E cells was set to 100 and values for cyclosporine treatment represent transcript abundance relative to control. Non-parametric Mann-Whitney-U-Test was used to compare cyclosporine treated and control groups. Results are considered significant at p < 0.05 (gene names and p-values in bold).
Germany). PCR was done in a mixture containing a cDNA equivalent to 25 ng of total RNA, 1 \( \mu \)M of each primer, 0.25 mM dNTP mixture, 0.625 U Thermostart-Taq (Abgene, Hamburg, Germany) and 1\( \times \) PCR-buffer (Abgene, with 1.5 mM MgCl\(_2\)) in a total volume of 20 \( \mu \)l. PCR-reactions were carried out with a thermocycler (T3, Biometra, Göttingen, Germany) with the following conditions: initial denaturation at 95°C for 15 min (Thermostart activation), denaturation at 94°C for 30 sec, annealing at different temperatures for 45 sec (see below), extension at 72°C for 45 sec, final extension at 74°C for 10 min. The following primer pairs were used: HNF4\( \alpha \) (human, NM_000457), fwd: CTG CTC GGA GCC ACA AAG AGA TCC ATG, rev: ATC ATC TGC CAC GTG ATG CTC TGC A (50°C, 29cyc); HNF1\( \alpha \) (human, NM_000545), fwd: TCT ACA ACT GGT TTG CCA ACC, rev: GGC TTC TGT ACT CAG CAG GC (50°C, 33cyc); ApoC2 (apolipoprotein C2) (human, NM_000483), fwd: CCT CCC AGC TCT GTT TCT TG, rev: GCT GCT GTG CTT TTG CTG TA (60°C, 38cyc); GK (glycerol kinase) (human, NM_203391), fwd: AGT CTC GAA CCC GAG GAT TT, rev: GTC ATG CAG CAA GTG GCT TA (55°C, 36cyc); PKLR (pyruvate kinase) (human, NM_000298), fwd: GTG GAG AGC TTT GCA GGT TC, rev: GCC GAT TTT CTG GAC CAC TA (55°C, 36cyc); ALDOB (aldolase B)

**Figure 4.** Gene expression of HNF4\( \alpha \) in liver of human patients. Gene expression was determined by real-time qPCR in \( n = 14 \) patients. Characteristics of patients are given in Table 7.
doi:10.1371/journal.pone.0004662.g004

**Table 6.** HNF4\( \alpha \) isoform expression in INS-1E cells.

| HNF4\( \alpha \) isoform | Mean ± SD |
|-------------------------|-----------|
| HNF4\( \alpha \)P1       | 0         |
| HNF4\( \alpha \)P2       | 418.18 ± 225.99 |

HNF4\( \alpha \) isoform expression was measured by real time qRT-PCR in INS-1E cells after 6 days in culture (\( n = 3 \), respectively). Gene expression was determined relative to expression of mitATPase6, which served as a housekeeping gene. Gene expression in rat liver served as positive control for HNF4\( \alpha \)P1 expression, gene expression in rat pancreas served as positive control for HNF4\( \alpha \)P2 expression.
doi:10.1371/journal.pone.0004662.t006

**Figure 5.** Cyclosporine inhibits NFAT binding to the P2 promoter of HNF4\( \alpha \). (A) Electrophoretic mobility shift assays with 2.5 \( \mu \)g Caco-2 cell nuclear extract [control or cyclosporine treatment, 25 \( \mu \)M (30 \( \mu \)g/ml) for 72 h] and \(^{32}\)P labeled oligonucleotides to probe for DNA binding to the NFAT binding site within the HNF4\( \alpha \)P2 promoter (NFAT-site in HNF4\( \alpha \)P2). In EMSA supershift assays an antibody directed against NFAT was added. Control and treated probes were run on same gels. (B) Dried EMSA gels were analyzed with a Molecular Imager (BioRad) using the Quantity One software (BioRad). NFAT binding of control extracts was set to 100% and inhibition of binding after treatment with cyclosporine [25 \( \mu \)M (30 \( \mu \)g/ml) for 72 h] was quantified.

Real-time RT-PCR measurement was done with the Lightcycler (Roche Diagnostics, Mannheim, Germany) with the following conditions: denaturation at 94°C for 120 sec, annealing at different temperatures for 8 sec (see below), extension at 72°C for different times (see below), fluorescence at different temperatures (see below). The PCR reaction was stopped after a total of 40–45 cycles and at the end of each extension phase, fluorescence was observed and used for quantification within the linear range of amplification. Exact quantification was achieved by serial dilution with cDNA produced from total RNA extracts using 1:5 dilution steps. Gene expression levels were normalized to different primer pairs were used: HNF4α (rat, AF329936), fwd: CTC CAG TGG CGA GTC CTT AT, rev: TCA GGC TGC TGC TGA AGA AT (60°C, 7 sec, 87°C); HNF4z (mouse, NM_008261), fwd: ACA GGT CCC CAT CTG AAG, rev: TCT CTT TCT TCA TGC CAG (68°C, 12 sec, 86°C); PCK1 (rat, NM_190870), fwd: AGG CCA TTA AGA CCA TCC AG, rev: TTC GTA GAC GGG GAC AC (60°C, 13 sec, 87°C); INS1 (rat, NM_019129), fwd: AGA CCA TCA GGA AGG TG, rev: CCA GTT GAT GGA GGC AGG AGC AG (68°C, 14 sec, 88°C); INS2 (rat, NM_019130), fwd: CAG CAC CTT TGT GGT TCT CA, rev: CAG TGC CAA GGT CTG AAG GTG (60°C, 7 sec, 87°C); cyclophilin rat, NM_017101), fwd: TTT CTT GCT GTG CTA GC, rev: CTG CCT GCT CCT GGA CCC AA (55°C, 15 sec, 82°C); mitATPase (rat, NC_001807), fwd: CTA AAG GAC GAA CCT GA, rev: TGG CCT GCA GTA ATG TT (55°C, 13 sec, 83°C).

Statistical analysis

All values are expressed as mean±standard deviation. To determine significance between two groups, comparison was made using the non-parametric two-tailed Mann-Whitney-U-Test. Therefore, Statistica software, version 7.1 (StatSoft) was used. The results are considered significant when the p value was less than 0.05.

Acknowledgments

We thank S. Marschke, A. Plaune and A. Schulmeyer for valuable technical assistance, S. Reymann for assistance in bioinformatics and advice on design of PCR primers, Dres. W. Lanz and H. Ruetten for providing pancreas of ZDF rats, Dr. C. Wollheim for providing INS-1E cells, Dr. J. Miyazaki for providing MIN6 cells and Dr. S. Lenzen for providing RIN-m5F cells.

Author Contributions

Conceived and designed the experiments: JB MN. Performed the experiments: JB MN. Analyzed the data: JB MN. Wrote the paper: JB MN.
