(Dated: July 29, 2018)

We study the indirect exchange interaction between two localized magnetic moments, known as Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction, in a one-dimensional spin-polarized electron gas. We find explicit expressions for each term of this interaction, study their oscillatory behaviors as a function of the distance between two magnetic moments, $R$, and compare them with the known results for RKKY interaction in the case of one-dimensional standard electron gas. We show this interaction can be written in an anisotropic Heisenberg form, $E(\vec{R}) = \lambda^2 \chi_{xx}(S_{1x}S_{2x} + S_{1y}S_{2y}) + \lambda^2 \chi_{zz} S_{1z}S_{2z}$, coming from broken time-reversal symmetry of the host material.

I. INTRODUCTION

The well-known RKKY interaction between two localized magnetic moments in a host solid was originally derived for the free electron gas[10,11] and continues to be an active and important research field in different classes of materials with different symmetries[12]. Straightforward calculations lead to the oscillatory Heisenberg form of RKKY interaction, \( J\vec{S}_1 \cdot \vec{S}_2 \), in a two- and three-dimensional electron gas, but the result which provides the correct answer to the same problem in a one-dimensional (1D) electron gas was always challenging[21,22]. In this brief manuscript, we study this effect for the case of one-dimensional electron gas, which provides a useful addition to the literature.

In the presence of spin-orbit coupling, Dzyaloshinsky and Moriya (DM) have used the lattice models to show[23,24] vector and tensor interaction terms appear in addition to the scalar RKKY interaction, so the \( \vec{R} \)-dependent part of the change in the energy of the system after adding two localized magnetic moments can be written as \( E(\vec{R}) = J\vec{S}_1 \cdot \vec{D} \cdot \vec{S}_2 + \sum \vec{S}_1 \cdot \vec{S}_2 + \sum \vec{S}_1 \cdot \vec{S}_2 \). For the case of spin-polarized electron gas, due to the presence of inversion symmetry, one may expect \( \vec{D} = 0 \), but broken time reversal symmetry leads to an extra term which has the form of tensor DM interaction, \( \vec{S}_1 \cdot \vec{\Gamma} \cdot \vec{S}_2 \). This term causes the anisotropy Heisenberg-form of the interaction and beat-pattern in their oscillatory behaviors. Studying of the RKKY and DM interactions in a host solid with broken symmetries plays a crucial role to understand the physics of the magnetic chiral ordering and Skyrmions[13,19,20,24].

II. GENERAL FORMALISM FOR \( \vec{R} \)-DEPENDENT PART OF ENERGY

The second localized magnetic moment, \( \vec{S}_2 \), located at \( \vec{r} = \vec{R} \), interacts with the wave functions of the electrons perturbed by the first localized magnetic moment, \( \vec{S}_1 \), which is located at the origin, \( \vec{r} = 0 \). The net interaction can be written as \( E = E_0 + E(\vec{R}) \), where \( E_0 \) is a constant shift in the energy of the system and can be evaluated using the first order perturbation theory. Defining the contact interaction between the localized moments and the spin of electrons in the operator forms of \( \hat{V}_1 = -\lambda \sum_{\sigma\sigma'} |0\sigma\rangle \langle \sigma| \vec{S}_1 \cdot \vec{s} \langle \sigma' | \) and \( \hat{V}_2 = -\lambda \sum_{\sigma\sigma'} |\vec{R}\sigma\rangle \vec{S}_2 \cdot \vec{s} \langle \vec{R}\sigma'| \), and using Lippmann-Schwinger equation[27] one can find the \( \vec{R} \)-dependent part of this interaction as

\[
E(\vec{R}) = -\frac{\lambda^2}{\pi} \Im \int_{-\infty}^{\infty} Tr \left[ G(0, \vec{R}, E) \vec{S}_2 \cdot \vec{s} G(\vec{R}, 0, E) \vec{S}_1 \cdot \vec{s} \right] dE.
\]

(1)

Here, \( \lambda \) is a phenomenological constant responsible for the strength of the contact interaction between localized magnetic moments and the spin of electrons, and \( G(\vec{R}, 0, E) \) and \( G(0, \vec{R}, E) \) are the unperturbed retarded Green’s function matrices which their elements can be found using

\[
G_{\sigma\sigma'}(\vec{r}_1, \vec{r}_2, E) = \sum_{k\nu} \frac{\psi_{k\nu}^\dagger(\vec{r}_1, \sigma_1) \psi_{k\nu}(\vec{r}_2, \sigma_2)}{E + i\mu - \varepsilon_{k\nu}},
\]

(2)

with \( \mu \to 0^+ \) and \( \nu \) as the band index. Although Eq. (1) is a known formula and has been widely used in the literature[5,8,15], working through its derivation still holds value. A pedagogical derivation of this equation, which is given in the Appendix, provides some important information about limitation of using this equation to get the indirect exchange interaction between two localized magnetic moments, and can be helpful for both experts and beginners in this research field. A very essential point that can be extracted is to get the result as Eq. (1), the order of integration between \( E \) and \( \vec{k} \), immediately after Eq. (23) in the Appendix, has been changed. If the Fubini’s condition[13,16] is not satisfied, changing the order of integration in a double-integral can lead to a different result. For the case of one-dimensional electron gas, one can immediately find that Fubini’s condition is not satisfied.

III. GREEN’S FUNCTION MATRICES

For the case of one-dimensional spin-polarized electron gas the unperturbed eigenstates and energy bands are defined as \( |\vec{k}\sigma\rangle = \frac{1}{\sqrt{L}} e^{i\vec{k} \cdot \vec{r}} |\sigma\rangle \) and \( \varepsilon_{k\sigma} = \frac{\hbar^2 k^2}{2m} + \Delta \), respectively, where we have assumed +(-) sign for spin-down (-up) states. To find the elements of Green’s function matrix, one can use Eq. (2) and find the result
Adding this constant to last result for integral of double integral is responsible for the dependence of the double integral on the order of integration. 

With a delta-function as the potential, complex-plane integration techniques lead to the wrong results for the RKKY interaction. For example, for the case one-dimensional electron gas.

If we set $\Delta = 0$, we can easily find the results for the Green’s function matrices for the case of standard one-dimensional electron gas.

Similar methods can be used to find the magnetic interaction between two localized moments in a spin-polarized one-dimensional electron gas.

Discussions – Putting the Green’s function matrices found in Eq. (3) into the Eq. (1) and applying standard complex-plane integration techniques lead to the wrong results for the RKKY interaction. For example, for the case of standard one-dimensional electron gas, it leads to the wrong unphysical answer to the problem, $E(\vec{R}) = J \hat{S}_1 \cdot \hat{S}_2$, with

$$J = \frac{\lambda^2 m}{2\pi} \text{Si}(2k_F R),$$

where $\text{Si}(x)$ is the sine intergral,

$$\text{Si}(x) = \int_0^x \frac{\sin(t)}{t} dt. \quad (6)$$

Here, we would like to emphasize using Eq. (1) with the Green’s function matrices found in Eq. (3) leads to the wrong unphysical results for both the cases of standard and spin-polarized one-dimensional electron gas. In a similar work, Imamura et al. have used the same method. To obtain physical answer to the problem, the authors inserted a constant, $-\lambda^2 m/2\pi$ found by Yafet, to the last result. Yafet explained that the singularities in the intergrant of double integral is responsible for the dependence of the double integral on the order of integration. Adding this constant to last result for $J$ leads to the right answer to the problem.

On the other hand, Giuliani and coauthors provided a very pedagogical method to obtain the right answer to the problem. This method is based on finding the delocalized eigenstates of the one-dimensional Schrodinger equation with a delta-fucon as the potential, $V(x) = u \delta(x)$ when $u \to 0^+$, and then using them to find the electronic density. Similarly, one can use these eigenstates to find the full Green’s function of the system as $G_F(r, rt, E) = g(r, rt, E) \sigma_0$, where

$$g(r, rt, E) = \frac{1}{2\pi} \left\{ \int_0^{2\pi} \cos(k | r - r' |) dk - \int_0^{2\pi} \frac{2u^2}{4k^2 + u^2} \cos(k | r + r' |) dk + \int_0^{2\pi} \frac{4ku}{4k^2 + u^2} \sin(k | r + r' |) dk \right\}. \quad (7)$$

The last result is valid for any value of $u$. Now using the full and unperturbed Green’s function matrices, it is convenient to find the change in the local electronic density, $\delta n(x) = \frac{-u}{\pi} \text{Si}(2k_F |x|), \quad (8)$

where $\text{si}(x) = \text{Si}(x) - \frac{x}{2\pi}$. To get the last result, one may need to use the following Dirac delta function equalities

$$\delta(k) = \frac{2}{\pi} \lim_{u \to 0^+} \frac{u}{4k^2 + u^2}, \quad (9)$$

$$\delta(E) = \frac{1}{\pi} \lim_{\mu \to 0^+} \text{Im} \left[ \frac{1}{E + i\mu} \right],$$

$$\delta(k^2 - \frac{2mE}{\hbar^2}) = \sqrt{\frac{\hbar^2}{8mE}} \left\{ \delta(k - \sqrt{\frac{2mE}{\hbar^2}}) + \delta(k + \sqrt{\frac{2mE}{\hbar^2}}) \right\}. \quad (9)$$

Similar methods can be used to find the magnetic interaction between two localized moments in a spin-polarized one-dimensional electron gas.
IV. One-dimensional Spin-Polarized Electron Gas

Writing the interaction in the form of \( E = E_0 + E(\vec{R}) \), where \( E_0 \) is a constant shift to the energy of the system and \( E(\vec{R}) \) is the distance-dependent part of the interaction, and using the first-order perturbation theory, one can easily find

\[
E_0 = \sum_{k\nu} \langle \vec{k}\nu | \hat{V}_1 + \hat{V}_2 | \vec{k}\nu \rangle, \\
= -\frac{\lambda h}{2\pi} (S_{1z} + S_{2z})(k_{F\uparrow} - k_{F\downarrow}).
\]

(10)

Choosing the \( z \)-direction as the quantization axis leads to this non-zero \( E_0 \) for spin-polarized electron gas. For the case of standard one-dimensional electron gas, \( k_{F\uparrow} = k_{F\downarrow} \) and \( E_0 = 0 \).

Using similar methods, and defining \( \delta = \sqrt{2m\hbar^2}\Delta \), we found the \( \vec{R} \)-dependent part of the interaction between two localized magnetic moments in the one-dimensional spin-polarized electron gas has the form of \( E(\vec{R}) = J\vec{S}_1 \cdot \vec{S}_2 + \vec{S}_1 \cdot \vec{T} \cdot \vec{S}_2 \), where

\[
J = \frac{\lambda^2 m}{4\pi} \{ \text{si}(2k_{F\uparrow}R) + \text{si}(2k_{F\downarrow}R) \},
\]

(11)

and the survived tensor interaction has the form of:

\[
\Gamma = \begin{pmatrix}
P & 0 & 0 \\
0 & P & 0 \\
0 & 0 & 0
\end{pmatrix},
\]

(12)

where

\[
P = \frac{\lambda^2 m}{2\pi} \left( -\int_{0}^{k_{F\uparrow}} e^{-\sqrt{\delta^2 + k^2}R}\cos[kR]dk \\
+ \int_{\sqrt{\delta^2}}^{k_{F\uparrow}} \sin[\sqrt{\delta^2 + k^2}R]\cos[kR]dk \\
+ \int_{0}^{k_{F\downarrow}} \sin[\sqrt{\delta^2 + k^2}R]\cos[kR]dk - g \right),
\]

(13)

with

\[
g = \begin{cases}
J & \text{if } \delta \neq 0, \\
J + \frac{\pi}{2} & \text{if } \delta = 0.
\end{cases}
\]

(14)

One can immediately learn the vector DM, \( \vec{D} \), vanishes. This result could be physically expected, based on the lack of explicit spin-orbit coupling and the presence of inversion symmetry in the system. Note that for an unpolarized electron gas \( \Delta = 0 \), so \( \delta = 0 \) which leads to \( k_{F\uparrow} = k_{F\downarrow} \), and finally, above expressions lead to \( P = 0 \) and the well-known \( J \) for the case of one-dimensional electron gas\(^{17,18} \). Adding all of the energy terms, it is convenient to find an anisotropic Heisenberg form for this interaction,

\[
E(\vec{R}) = \lambda^2 \chi_{xx}(S_{1x}S_{2x} + S_{1x}S_{2x}) + \lambda^2 \chi_{zz} S_{1z}S_{2z},
\]

(15)

with \( \chi_{xx} = (P + J^{1D})/\lambda^2 \) and \( \chi_{zz} = J^{1D}/\lambda^2 \). Oscillatory behaviors of \( \chi_{xx} \) and \( \chi_{zz} \) as a function of \( R \), have been studied in the Fig. (1).

To study the long-range behavior of \( \chi_{zz} \), one can write the sine integral in terms of auxiliary functions, \( \text{Si}(x) \simeq \frac{\pi}{2} - f(x)\cos(x) - g(x)\sin(x) \), then use asymptotic series,

\[
f(x) \simeq \frac{1}{x}(1 - \frac{2!}{x^2} + \frac{4!}{x^4} - \frac{6!}{x^6} + ...),
\]

\[
g(x) \simeq \frac{1}{x^2}(1 - \frac{3!}{x^2} + \frac{5!}{x^4} - \frac{7!}{x^6} + ...),
\]

(16)
so we will get \( \sin(x) \approx -\cos(x)/x \) which leads to the result
\[
\chi_{zz} \approx \frac{m}{4\pi} \left( \frac{\cos(2k_{F\uparrow}R)}{2k_{F\uparrow}R} + \frac{\cos(2k_{F\downarrow}R)}{2k_{F\downarrow}R} \right),
\]
for large distances, \( R \gg k_{F\uparrow}^{-1} \) and \( k_{F\downarrow}^{-1} \). This result is compatible with the well-known long-range behavior of RKKY interaction in \( n \)-dimension, viz.,
\[
\chi(R) \propto \frac{\cos(2k_{F}R - \frac{(n-1)\pi}{2})}{(2k_{F}R)^{n}}.
\]

The last result is different from what Sobota et al.\cite{11} reported and provides right answer for the long-distance behavior of RKKY interaction in \( n \)-dimension.

It is worthwhile to mention that, disregarding the coefficients and the decay-factor \( R^{-n} \), the long-distance behaviors of \( J \) for the cases of one- and three-dimensional spin-polarized electron gas show a similar pattern, viz., \( J \propto \cos(k_{F\uparrow}R + k_{F\downarrow}R) \times \cos(k_{F\uparrow}R - k_{F\downarrow}R) \), while for the case of two-dimensional spin-polarized electron gas, \( \sin(k_{F\uparrow}R + k_{F\downarrow}R) \times \cos(k_{F\uparrow}R - k_{F\downarrow}R) \) form of oscillatory behavior is expected. This fact can be found by comparing Eq. (17) with the final results for long-distance behaviors of \( J \) in a two- and three-dimensional spin-polarized electron gas\cite{17,18}, and is valid for the case that \( \delta \ll k_{F\uparrow} \) and \( k_{F\downarrow} \).

V. SUMMARY

We found an anisotropic Heisenberg form for the indirect exchange interaction between two localized magnetic moments in a one-dimensional spin-polarized electron gas. Explicit expressions are found for each term, and long-range behaviors of them have been studied. In this case, \( \cos(k_{F\uparrow}R - k_{F\downarrow}R) \) and \( \cos(k_{F\uparrow}R + k_{F\downarrow}R) \) control the long-distance beat-pattern and oscillatory behavior of \( J \), respectively, and the magnetic interaction falls off as \( R^{-1} \). Disregarding the coefficients and the decay-factor \( R^{-n} \), the same argument is valid for the case of three-dimensional spin-polarized electron gas. Setting \( k_{F\uparrow} = k_{F\downarrow} \) leads to the standard result for the RKKY interaction \( J \) for the one-dimensional electron gas. Numerical results showed a beating pattern due to the interference between the two Fermi momenta \( k_{F\uparrow} \) and \( k_{F\downarrow} \) for the two different spin channels.

ACKNOWLEDGEMENTS

VI. APPENDIX

Here, we derive a general expression for the interaction between two localized magnetic moments in a host material, known as RKKY and Dzyaloshinsky-Moriya interactions, using Lippmann-Schwinger equation\cite{22}. Although the final result of this Appendix, Eq. (\ref{eq:21}), is known in the literature, working through this derivation is worthwhile. It can be useful for both beginners and experts in the field, and at the same time it provides some important information about the final result and its limitations.

First, we put the first localized magnetic moment $\vec{S}_1$ at $\vec{r}_1 = \vec{0}$ and it perturbs the state of electrons, then second localized magnetic moment $\vec{S}_2$ will be located at $\vec{r}_2 = \vec{R}$ and interacts with the perturbed electrons of the host. Showing the perturbed and unperturbed states by $| \vec{k}\nu \rangle$ and $| k\nu \rangle$, respectively, one can use Lippmann-Schwinger equation to find

$$| \vec{k}\nu \rangle \simeq | k\nu \rangle + \hat{G} \hat{V}_1 | k\nu \rangle,$$

where $\nu$ is the band index, $\hat{G}(E) = (E + i\mu - \hat{H})^{-1}$ with $\mu \to 0^+$, is the unperturbed retarded Green’s function operator to be evaluated at $E = \varepsilon_{k\nu}$, and $\hat{V}_1$ indicates the perturbing potential operator applied by the $i$-th localized magnetic moment, and can be written as

$$\hat{V}_1 = -\lambda \sum_{\sigma\sigma'} | \vec{r}_i \sigma \rangle \langle \vec{r}_i \sigma' | \vec{S}_i \cdot \vec{s} \sigma' \sigma \sigma. \quad (20)$$

This perturbing potential has the contact interaction forms of $V_1(\vec{r}) = -\lambda \delta(\vec{r} - \vec{R}) \vec{S}_1 \cdot \vec{s}$ and $V_2(\vec{r}) = -\lambda \delta(\vec{r} - \vec{R}) \vec{S}_2 \cdot \vec{s}$. Here, $\vec{s}$ is the spin of electrons and $\lambda$ is a phenomenological constant. In Eq. (20), $\vec{r}_i = \vec{0}$ and $\vec{R}$ for the first and second localized moments, respectively. Localized moment located at $\vec{R}$ interacts with the perturbed wavefunctions of the electrons, found in Eq. (19), so one can write the interaction total energy as $E = \sum_{\vec{k}\nu} \langle \vec{k}\nu | \hat{V}_2 | \vec{k}\nu \rangle + \langle \vec{k}\nu | \hat{V}_1 | \vec{k}\nu \rangle$, where $\text{occ}$ stands for occupied and shows the fact that only occupied states will be taken into account. Writing this energy in the form of $E = E_0 + E(\vec{R})$, we have

$$E_0 = \sum_{\vec{k}\nu} \langle \vec{k}\nu | \hat{V}_1 + \hat{V}_2 | \vec{k}\nu \rangle,$$

$$E(\vec{R}) = \sum_{\vec{k}\nu} \langle \vec{k}\nu | \hat{V}_2 \hat{G} \hat{V}_1 | \vec{k}\nu \rangle + \text{h.c.} = T + T^*,$$

where $E_0$ is a constant shift to the energy of the system $E(\vec{R})$ is the $\vec{R}$-dependent part of the total energy. For the systems without any broken symmetries or the cases that summation over all the spin of electrons is zero, in other words the system is not spin-polarized, $E_0$ will vanish. Based on this fact, we only focus on $E(\vec{R})$ which is the more interesting part of the total energy. Using the completeness relations: $\sum_{\sigma} \int d^nr = \sum_{\vec{r}_\sigma} | \vec{r}_\sigma \rangle \langle \vec{r}_\sigma | = 1$ and $\sum_{\vec{k}\sigma} | \vec{k}\sigma \rangle \langle \vec{k}\sigma |$ = $\sum_{\vec{k}\nu} | \vec{k}\nu \rangle \langle \vec{k}\nu | = 1$, and defining $\psi_{\vec{k}\nu}(\vec{r} , \sigma) = | \vec{r} \sigma \rangle | \vec{k}\nu \rangle$ we find

$$T = \lambda^2 \sum_{\vec{k}\nu} \sum_{\sigma_1 \sigma_2} \psi^*_{\vec{k}\nu}(\vec{R}, \sigma_1) (\sigma_1 | \vec{S}_2 \cdot \vec{s} G(\vec{R}, 0, \varepsilon_{\vec{k}\nu}) \vec{S}_1 \cdot \vec{s} | \sigma_2) \psi_{\vec{k}\nu}(0, \sigma_2). \quad (22)$$

In the above equation, $G(\vec{R}, 0, \varepsilon_{\vec{k}\nu})$ is the retarded Green’s function matrix evaluated at $E = \varepsilon_{\vec{k}\nu}$ which its elements can be found using

$$G_{\sigma_1 \sigma_2}(\vec{r}_1, \vec{r}_2, E) = \sum_{\vec{k}\nu} \frac{\psi^*_{\vec{k}\nu}(\vec{r}_1, \sigma_1) \psi_{\vec{k}\nu}(\vec{r}_2, \sigma_2)}{E + i\mu - \varepsilon_{\vec{k}\nu}}, \quad (23)$$

with $\mu \to 0^+$. We will now use the facts $G(\vec{R}, 0, \varepsilon_{\vec{k}\nu}) = \int_{-\infty}^{\infty} G(\vec{R}, 0, E) \delta(E - \varepsilon_{\vec{k}\nu})$ and $\int_{-\infty}^{\infty} dE \times \sum_{\vec{k}\nu} \rightarrow \int_{-\infty}^{\infty} dE \times \sum_{\vec{k}\nu}^\text{occ}$ to write $T$ in the form of

$$T = \lambda^2 \int_{-\infty}^{E_F} dE \sum_{\sigma_1 \sigma_2} | \vec{S}_2 \cdot \vec{s} G(\vec{R}, 0, E) \vec{S}_1 \cdot \vec{s} | \sigma_2 \rangle \langle \vec{S}_2 \cdot \vec{s} G(\vec{R}, 0, E) | \vec{S}_1 \cdot \vec{s} | \sigma_1 \rangle \psi^*_{\vec{k}\nu}(\vec{R}, \sigma_1) \psi_{\vec{k}\nu}(0, \sigma_2) \delta(E - \varepsilon_{\vec{k}\nu}). \quad (24)$$
Here, there is an important point: to get the final result we have changed the order of integration over \( \vec{k} \) and \( E \) in Eq. 24. As it has been said in the paper, if Fubini’s condition is not satisfied, changing the order of integration in a double-integral can change the result of integration. It is important to emphasize that when one uses the last result of this Appendix, Eq. 1, to find the magnetic interaction, it should be carefully evaluated, and in the case that the result does not make physical sense, the method of integration over \( \vec{k} \), which is using \( E(\vec{R}) = 2 R e[T] \) with \( T \) defined in the Eq. 22, should be used.

The \( \delta \)-function in Eq. 24 can be expressed in a form that it is useful to make Green’s function. The equality \( \lim_{\mu \rightarrow 0} (x \pm i \mu)^{-1} = P((x^+))^\pm i \delta(x) \) leads to the fact \( \delta(x) = (i/2\pi) \lim_{\mu \rightarrow 0} ((x \pm i \mu)^{-1} - (x - i \mu)^{-1}) \). Expanding \( \delta(E - \varepsilon_{\vec{k} \nu}) \) in Eq. 24 in that form, and using \( \sum_\sigma |\sigma \rangle \langle \sigma | = 1 \) and \( E(\vec{R}) = 2 R e[T] \) with \( T \) defined in the Eq. 22 result the \( \vec{R} \)-dependent part of the energy as

\[
E(\vec{R}) = -\frac{\lambda^2}{\pi} \int_{-\infty}^{E_F} \text{Tr} \left[ G(0, \vec{R}, E) \vec{S}_2 \cdot \vec{s} G(\vec{R}, 0, E) \vec{S}_1 \cdot \vec{s} \right] dE + \frac{\lambda^2}{\pi} \int_{-\infty}^{E_F} \text{Tr} \left[ G^A(0, \vec{R}, E) \vec{S}_2 \cdot \vec{s} G(\vec{R}, 0, E) \vec{S}_1 \cdot \vec{s} \right] dE
\]  

(25)

where \( G^A(0, \vec{R}, E) \) is Advanced Green’s function matrix which its elements can be found using

\[
G^A_{\sigma_1, \sigma_2}(\vec{r}_1, \vec{r}_2, E) = \sum_{k \nu} \frac{\psi_{k \nu}^*(\vec{r}_1, \sigma_1) \psi_{k \nu}^*(\vec{r}_2, \sigma_2)}{E - i \mu - \varepsilon_{k \nu}},
\]

(26)

with \( \mu \to 0^+ \). It is convenient to show that second term in Eq. 25 turns out to be zero. To show this, one can easily expand the Green’s function matrices in terms of Pauli matrices, then use the fact that \( G^A(0, \vec{R}, E) = G^I(\vec{R}, 0, E) \). The last fact leads to the desired result of this Appendix,

\[
E(\vec{R}) = -\frac{\lambda^2}{\pi} \int_{-\infty}^{E_F} \text{Tr} \left[ G(0, \vec{R}, E) \vec{S}_2 \cdot \vec{s} G(\vec{R}, 0, E) \vec{S}_1 \cdot \vec{s} \right] dE.
\]
