CHAPTER 2

Predictors of transitions from single to multiple job holding: Results of a longitudinal study among employees aged 45-64 in the Netherlands

ABSTRACT

Objectives. To construct prediction models for transitions to combination multiple job holding (MJH) (multiple jobs as an employee) and hybrid MJH (being an employee and self-employed), among employees aged 45-64.

Methods. A total of 5187 employees in the Netherlands completed online questionnaires annually between 2010 and 2013. We applied logistic regression analyses with a backward elimination strategy to construct prediction models.

Results. Transitions to combination MJH and hybrid MJH were best predicted by a combination of factors including: demographics, health and mastery, work characteristics, work history, skills and knowledge, social factors, and financial factors. Not having a permanent contract and a poor household financial situation predicted both transitions. Some predictors only predicted combination MJH, e.g. working part-time, or hybrid MJH, e.g. work-home interference.

Conclusions. A wide variety of factors predict combination MJH and/or hybrid MJH. The prediction model approach allowed for the identification of predictors that have not been previously studied.
INTRODUCTION

In many industrialised countries, a substantial proportion of workers hold multiple paid jobs, for instance, approximately 10% in Norway and the Netherlands (1), and 5% in the US (2). We define multiple job holding (MJH) as having more than one paid job. We distinguish two types of MJH: (i) having more than one job as an employee (combination MJH), or (ii) having one or more jobs as an employee while also being self-employed (hybrid MJH). MJH has been associated with increased flexibility in labour markets, higher job mobility and lower job security (3, 4). The few studies on the consequences of MJH have generally focused on health effects and have all been conducted in the US. These studies suggest that MJH is associated with an increased risk of injuries and less sleep (5, 6).

Although common in many labour markets, little is known about the reasons for MJH (7). In general, the few studies on determinants of MJH have focused on the hours-constraint hypothesis. According to this hypothesis, MJH is more likely to occur if a worker cannot work their preferred number of hours in their first job (8-10). Individuals may desire to work more hours if they cannot meet regular expenses or want to earn extra money (2, 11). Some studies have found that employees who work part-time or want to work additional hours are more likely to have multiple jobs (9, 12). However, other studies have shown that the hours-constraint hypothesis does not apply to all multiple job holders (10, 12).

A second hypothesis on reasons for MJH states that having multiple heterogeneous jobs can have non-pecuniary benefits, such as increased job satisfaction and the acquisition of new skills (heterogeneous jobs hypothesis) (13). Few studies have examined this hypothesis. Some of these studies, however, have found some preliminary support (10, 14). In addition, some studies examined ‘hedging’, that is, holding two or more jobs to prevent unemployment, and found little support for it (3, 11, 14).

Previous research has shown that reasons for MJH may differ between older and younger workers. For example, financial reasons are less common among older workers (2, 7). Qualitative studies have suggested that MJH might be a way for (older) workers to combine jobs with heterogeneous demands and resources, thereby improving their (sustainable) employability (15, 16). This may enable older workers to stay in paid employment, which is increasingly important in countries where workers are expected to participate in paid employment until later in life.

Although previous research on determinants of MJH provides valuable insights, these studies have focused on a limited set of determinants, generally related to the hours-constraint and heterogeneous-jobs hypotheses. The findings of these studies suggest that these two hypotheses do not apply to many multiple jobholders. Therefore, it is important to generate new hypotheses regarding who has multiple jobs and for which reason. Since little is known about the determinants of MJH among older employees and because these determinants
likely differ from younger workers’ determinants, the first aim of this study is to construct a prediction model for transitions from single job holding to MJH among employees aged 45-64. The results of these models may contribute to the development of new hypotheses. To construct prediction models, statistical methods are used to identify a combination of predictors, from a broad set of candidate predictors, that best predicts an outcome. We use the term predictor as it relates to elements of our prediction models only, and not to causal inference. We include candidate predictors that have been studied in previous studies, such as working hours, contract type, and household composition. Further, we include candidate predictors that have rarely been studied, but may be related to MJH, for instance because they have been found to be related to job-job mobility, such as health-related variables, physical work demands, psychosocial work factors and work motivation (17).

The second aim of this study is to explore whether the combination of predictors differs between combination MJH and hybrid MJH to account for heterogeneity among multiple job holders (16). We expect predictors of transitions to MJH to differ between combination and hybrid MJH, for example, because people choose self-employment partly because of their desire for independence (18) and since setting up a business requires resources such as capital (19).

MATERIALS AND METHODS

Study population
The study population consisted of participants of the Study on Transitions in Employment, Ability and Motivation (STREAM). STREAM is a Dutch longitudinal study of 15,118 persons aged 45–64 years at baseline (12,055 employees, 1029 self-employed persons, and 2034 not-working persons). The baseline age limit was set at 64 years (2010), because at the time the statutory retirement age in the Netherlands was 65 years. Follow-up continued after participants turned 65. The study population is extensively described elsewhere (20). In short, STREAM participants are members of an internet panel of GfK Intomart, a company specializing in market research. The study population was stratified by employment status and age at baseline. The population was selected to be representative of the Dutch population with respect to gender and educational level within age groups 45–49, 50–54, 55–59, and 60–64 years. Participants completed online questionnaires in October/November 2010 (T1), 2011 (T2), 2012 (T3), and 2013 (T4). For every completed questionnaire, the participant’s savings balance was increased by about €3.00.

In this study, we included STREAM participants who had one paid job as an employee at baseline (n=11,267) and who had participated in all four questionnaires (n=4006 employees lost to follow-up) (Figure 1). Employees who did not complete all four questionnaires were not
included, because we required yearly information on work status to determine whether or not a respondent had made a transition to combination MJH or hybrid MJH. We excluded employees if they had experienced a transition other than a transition to MJH (e.g. to unemployment or a new employer) to create a more homogenous reference group (n=2074 excluded).

Figure 1. Study population
### Table 1. Included predictors

| Predictors at baseline | Description and source |
|------------------------|------------------------|
| **Demographics**       |                        |
| Age                    | Continuous 45-64 Categorised: 1. 45-49 2. 50-54 3. 55-59 4. 60-64 |
| Gender                 | Dichotomous: 0. Female 1. Male |
| Education              | Categorical: 0. Low 1. Medium 2. High |
| **Health and mastery** |                        |
| Self-perceived physical health | SF-12 |
| Self-perceived mental health | SF-12 |
| Vitality               | SF-36 |
| Depressive symptoms    | CES-D 10-item scale |
| Mastery                | Control over factors that influence life situations. Pearlin Mastery Scale |
| BMI                    | Calculated by dividing body weight in centimeters by body height in meters, squared. |
| Chronic disease        | We presented respondents with a list of chronic diseases and asked them to report which ones they suffered from. |
| Exercise norm          | How many days per week are you usually physically active for at least 30 minutes per day? |

1 Complaints of the hands or arms (also arthritis, repetitive strain injury (RSI)), complaints of the legs and feet (also arthritis), complaints of the back or neck (also arthritis, RSI), migraine or severe headache, cardiovascular diseases, asthma, bronchitis, emphysema, gastrointestinal disorders, diabetes, severe skin disease, psychological complaints/disorders, hearing problems, epilepsy, life-threatening diseases (e.g. cancer, acquired immune deficiency syndrome (AIDS)), and/or problems with vision.
### Table 1. Included predictors

| Scale/categories                        | Original | Used in analyses |
|----------------------------------------|----------|------------------|
| Demographics                           |          |                  |
| Age -                                  | Continuous 45-64 | Categorised: 1. 45-49 2. 50-54 3. 55-59 4. 60-64 |
| Gender -                               | Dichotomous: 0. Female 1. Male | Identical |
| Education -                            | Categorical: 0. Low 1. Medium 2. High | Identical |
| Health and mastery                    |          |                  |
| Self-perceived physical health SF-12   | Continuous (0-100) | Identical |
| Self-perceived mental health SF-12     | Continuous (0-100) | Identical |
| Vitality SF-36                         | Continuous (0-100) | Identical |
| Depressive symptoms CES-D 10-item scale| Continuous (0-100) | Dichotomised, cut-off point: 0.8 |
| Mastery                                | Continuous 0-4 | Identical |
| BMI                                    | Continuous (16.6-62.7) | Categorised: 0. Under-/normal weight (0-25) 1. Overweight (25-30) 2. Obese (>30) |
| Chronic disease                        | Dichotomised: 0. No 1. Yes |
| Exercise norm                          | Categorical: 1. 0 days 2. 1 day 3. 2 days 4. 3 days 5. 4 days 6. 5 days 7. 6 days 8. 7 days | Dichotomised: 0. 6 days or less 1. Seven days |

1. Complaints of the hands or arms (also arthritis, repetitive strain injury (RSI)), complaints of the legs and feet (also arthritis), complaints of the back or neck (also arthritis, RSI), migraine or severe headache, cardiovascular diseases, asthma, bronchitis, emphysema, gastrointestinal disorders, diabetes, severe skin disease, psychological complaints/disorders, hearing problems, epilepsy, life-threatening diseases (e.g. cancer, acquired immune deficiency syndrome (AIDS)), and/or problems with vision.
## Table 1. Continued

| Predictors at baseline | Description and source |
|------------------------|------------------------|
| **Work characteristics** |                         |
| Number of hours according to contract | How many hours per week do you work according to your contract? |
| Contract type | What type of contract do you have? |
| Number of employees working in organisation | About how many persons work at your company or institution? (Only count the number of persons at your office/location. If you don't know the number of persons exactly, please give an estimation). |
| Restructuring | Did the company you work for carry out a restructuring or reorganisation in the past 12 months? |
| Supervisor | Do you manage other workers in your present job? (please include personnel that you manage through others) |
| Physical demands | 5-item scale on the regular use of force, vibrating tools, awkward postures, and prolonged standing or squatting. Dutch Musculoskeletal Questionnaire (Hildebrandt, Bongers, Van Dijk, Kemper, & Dul, 2001). |
| Job demands | 4-item scale, Job Content Questionnaire (JCQ) (Karasek, 1985) |
| Mental demands | 3-item scale, NOVA-WEBA (Dhondt & Houtman, 1997) |
| Emotional demands | 3-item scale, Copenhagen Psychosocial Questionnaire (COPSOQ) (Kristensen, Hannerz, Høgh, & Borg, 2005) |
| Bullying | Respondents were asked the question: did you experience any bullying, intimidation, physical violence or unwanted sexual attention at work in the last 12 months by customers? |
| Social support | 4-item scale, Copenhagen Psychosocial Questionnaire (COPSOQ) (Kristensen et al., 2005) |
Predictors of transitions to multiple job holding

| Scale/categories                  | Original | Used in analyses |
|-----------------------------------|----------|------------------|
| **Continuous**                    |          | Dichotomised:    |
|                                   | (0-84)   | 0. Part-time (36 hours or less) |
|                                   |          | 1. Full-time (more than 36 hours) |
| **Categorical:**                  |          | Dichotomised:    |
| 1. Permanent                      |          | 0. No permanent contract |
| 2. Temporary with potential of permanent |          | 1. Permanent contract |
| 3. Temporary for a defined period of time |          |               |
| 4. Temporary employ, stand-by employee/substitute |          |               |
| 5. Sheltered employment           |          |               |
| **Reduced categories:**           |          |                 |
| 0. ≤ 49 persons                  |          |                 |
| 1. 50 to 249 persons             |          |                 |
| 2. ≥250 persons                  |          |                 |
| **Categorical:**                  |          | Dichotomised:    |
| 1. No                             |          | 0. No            |
| 2. Without compulsory redundancies|          | 1. Yes           |
| 3. With compulsory redundancies  |          |                 |
| **Categorical:**                  |          | Dichotomised:    |
| 1. No                             |          | 0. No            |
| 2. Yes, to 1-4 employees          |          | 1. Yes           |
| 3. Yes, to 5-9 employees          |          |                 |
| 4. Yes, to 10-49 employees        |          |                 |
| 5. Yes, to 50-99 employees        |          |                 |
| 6. Yes, to more than 99 employees |          |                 |
| **Continuous**                    |          | Identical        |
| 0-4                               |          |                 |
| **Continuous**                    |          | Identical        |
| 0-4                               |          |                 |
| **Continuous**                    |          | Identical        |
| 0-4                               |          |                 |
| **Continuous**                    |          | Identical        |
| 0-4                               |          |                 |
| **Continuous**                    |          | Dichotomised:    |
| 0-4                               |          | 0. No            |
| 1. Yes                            |          |                 |
| **Continuous**                    |          | Identical        |
| 0-4                               |          |                 |
### Table 1. Continued

| Predictors at baseline | Description and source |
|------------------------|-------------------------|
| Autonomy               | 5-item scale, Job Content Questionnaire (JCQ) (Karasek, 1985) |
| Age discrimination     | 4-item scale, based on Nordic Age Discrimination Scale (Furunes & Mykletun, 2010) |
| Presence of 10 work characteristics | Appreciation, interesting work, opportunities for learning and development, autonomy, good social climate, good supervisor, good salary, opportunities to work part-time, opportunity to determine one's own working hours, high job security |

#### Work history

- Number of years:
  - In a paid job
  - At current employer
  - In current function
  - In a physically demanding job
  - In an emotionally demanding job
  - In a mentally demanding job
  - Increase in working hours
  - Decrease in working hours
  - Demotion

#### Skills and knowledge

- Developmental pro-activity: The extent to which employees actively search for opportunities to enhance their skills and knowledge (van der Heijden, Schalk, van Veldhoven, van Veldhoven, & Dorenbosch, 2008).
- Training/education: Respondents were asked whether they attended a training course, congress, trade fair, or meeting of suppliers or branch association in the past 12 months.
- Match skills/knowledge and work: How do your knowledge and skills fit with your job?
Predictors of transitions to multiple job holding

| Scale/categories | Original | Used in analyses |
|------------------|----------|------------------|
| Autonomy         | 5-item scale, Job Content Questionnaire (JCQ) (Karasek, 1985) | Continuous, 0-4 | Identical |
| Age discrimination | 4-item scale, based on Nordic Age Discrimination Scale (Furunes & Mykletun, 2010) | Continuous, 0-4 | Identical |
| Presence of 10 work characteristics | | Categorical: 0. Not present at all, 1. Somewhat present, 2. Rather present, 3. Highly present | Dichotomised: 0. Not present (0 and 1), 1. Present (2 and 3) |
| Work history | Number of years: | Continuous | Identical |
| | In a paid job | | |
| | At current employer | Continuous | Categorised: 0. ≤2 years, 1. 3-5 years, 2. 6-10 years, 3. ≥11 years |
| | In current function | Continuous | Categorised: 0. 0 years, 1. 1-20 years, 2. > 20 years |
| | In a physically demanding job | Continuous | Categorised: 0. 0 years, 1. 1-20 years, 2. > 20 years |
| | In an emotionally demanding job | Continuous | Categorised: 0. 0 years, 1. 1-20 years, 2. > 20 years |
| | In a mentally demanding job | Continuous | Categorised: 0. 0 years, 1. 1-20 years, 2. > 20 years |
| | Increase in working hours | Dichotomous: 0. No, 1. Yes | Identical |
| | Decrease in working hours | Dichotomous: 0. No, 1. Yes | Identical |
| | Demotion | Dichotomous: 0. No, 1. Yes | Identical |
| | Skills and knowledge | Developmental pro-activity | Continuous (0-4) | Identical |
| | Match skills/knowledge and work | | Categorical: 0. Badly, 1. Moderately, 2. Reasonably, 3. Well | Dichotomised: 0. Badly (0 and 1), 1. Well (2 and 3) |
## Table 1. Continued

| Predictors at baseline | Description and source |
|------------------------|------------------------|
| Ability to re-educate to new profession | In the coming 12 months, will you be able to re-educate towards a new profession? |
| Ability to find a new employer | In the coming 12 months, will you be able to find a new employer? |

### Social factors

**Partner**
The candidate predictors on having a partner and having children living at home were created using the following two variables:

- How would you describe your household?
  1. Married or living together without children living at home
  2. Married or living together with children living at home
  3. Single-parent family
  4. Single
  5. Other

- And:
  - Is your partner currently:
    - Having one paid job as an employee (salaried employment)
    - Self-employed or entrepreneur
    - Unemployed
    - Work disabled
    - Housewife/househusband
    - Retired (early)
    - Studying
    - Doing volunteer work or volunteer aid

**Children living at home**
Dichotomous:
- 0. No
- 1. Yes

**Participation in:**

- **Volunteer work**
  Have you spent part of your time on one of the following activities in the past 12 months?
  - Volunteer work or charity work (for example unpaid work for a club, committee, health care institution, charitable institution, religious community, etc)
  - Volunteer aid (for example taking care of an invalid person in your close environment without being paid. Does not include looking after healthy children)
  - Household work (household work, taking care of children living at home)

- **Informal care**

- **Household activities**

**Work-home interference**
Missing or neglecting work because of family responsibilities

**Home-work interference**
Missing or neglecting family activities because of work
### Scale/categories

| Original                                                                 | Used in analyses               |
|--------------------------------------------------------------------------|--------------------------------|
| **Categorical:**                                                        | **Dichotomised:**              |
| 0. Totally disagree                                                     | 0. No (0, 1 and 2)             |
| 1. Disagree                                                             | 1. Yes (3 and 4)               |
| 2. Neutral                                                              |                                |
| 3. Agree                                                                |                                |
| 4. Totally agree                                                        |                                |
| **Partner**                                                              |                                |
| **Categorical:**                                                        |                                |
| 0. Working partner                                                      |                                |
| 1. Partner who does not work                                            |                                |
| 2. No partner                                                           |                                |

Outcome
Transitions from being an employee with a single job to MJH were identified using a question on the respondents’ work status. Participants indicated whether they were: (i) an employee with one job, (ii) an employee in more than one job, (iii) self-employed, (iv) unemployed, (v) work disabled, (vi) retired early, (vii) retired, (viii) studying, and/or (ix) housewife/househusband. Employees who reported having more than one job as an employee during follow-up (T2, T3, or T4) were classified as having made a transition to combination MJH. Those who reported having one or more jobs as an employee and being self-employed during follow-up were classified as having made a transition to hybrid MJH. If both transitions were made during follow-up, persons were classified according to their first transition. If a respondent transitioned back to a single job, then they were still categorised as having made a transition to combination MJH or hybrid MJH.

Predictors
All candidate predictors were assessed at baseline. Table 1 provides an overview of the candidate predictors, which were grouped in eight domains: demographic factors, health and mastery, work characteristics, work history, skills and knowledge, social factors, financial factors, and work motivation.

Statistical analyses
To achieve the study’s first aim, we used logistic regression analyses to create prediction models. We created separate prediction models for combination MJH and hybrid MJH. We used a backward elimination strategy to select predictors for the final models (30), because of the high number of candidate predictors and the relatively low number of events. The backward elimination process consisted of four steps, which were performed separately for combination MJH and hybrid MJH. First, we established univariable associations between the predictors and the outcome measures. To decrease the likelihood of eliminating relevant candidate predictors in the early steps of the elimination process, we used a high p-value (0.20; corresponding with 80% confidence intervals) as a threshold for elimination. Second, we performed multivariable analyses per domain, that is, demographics, health and mastery, work characteristics, work history, skills and knowledge, social factors, financial factors, and work motivation, using backward elimination. All predictor variables with p<0.20 were selected for the next step. Third, we conducted multivariable analyses using backward elimination to construct predictive model 1A (for combination MJH) and predictive model 1B (for hybrid MJH). Predictors with p<0.05 were retained in this step. No candidate predictors were included in the final prediction models by default. Finally, we examined whether or not models 1A and 1B were improved by adding interaction terms between predictors included in these models and educational level. The analyses described above were performed using SPSS. Bootstrapping was conducted to internally validate the model performance (1000 bootstraps using R) (31).
To achieve the study’s second aim, that is, to explore the differences between combination MJH and hybrid MJH, we constructed a model including all predictors in models 1A and 1B. This model was applied to combination MJH (model 2A) and hybrid MJH (model 2B). Three dimensions of the performance of models 1A, 1B, 2A, and 2B were assessed: explained variance (Nagelkerke R²), discriminatory power (C-statistic), and goodness-of-fit (Hosmer and Lemeshow test). The Hosmer and Lemeshow test was not internally validated, since there is no method to correct this test using bootstrapping.

**Ethics**

The medical ethics committee of VUmc declared that the collection of the data used in this study was not subject to the Medical Research Involving Human Subjects Act. At the start of the online questionnaire, respondents received information stating that their privacy was guaranteed, all answers were confidential, and all data were stored in secured computer systems.

**RESULTS**

In total, 5187 employees were included in this study. Just over a quarter of the participants (25.8%) were 45-49 years at baseline, 29.4% were 50-54 years, 32.2% were 55-59 years, and 12.6% were 60-64 years. A total of 43.6% of the study population was female and education level was high for 34%, intermediate for 39%, and low for 27%. Characteristics of the study population are further described in Table 2.

Respondents who were lost to follow-up had worked for a shorter period at their current employer (15.7 versus 17.2 years), less often attended training or education (72% vs 77%), and more frequently reported having a good household financial situation (54% vs 48%).

In total, 175 employees had made a transition to combination MJH and 101 to hybrid MJH. Transitions to combination MJH were most prevalent among employees working in hospitality, agriculture or health care. Transitions to hybrid MJH were most prevalent among employees working in construction, or financial services (data not shown). Table 2 presents the results of the univariable analyses (only predictors included in model 1A or 1B are shown). Having a part-time contract only predicted combination MJH. A high educational level, higher mastery and work-home interference only predicted hybrid MJH. In the univariable analyses per domain, no predictors in the work motivation domain were retained for transitions to combination MJH.

In multivariable analysis, type of contract and household financial situation predicted transitions to combination MJH (model 1A) and hybrid MJH (model 1B) (Table 3). Other factors only contributed to the prediction of one of these transitions. Transitions to combination

**Knowledge and skills**

| Ability to find a new employer in the coming 12 months | - | 1.7 | 1.0 – 3.0 |

**Social factors**

| Children living at home (yes) | 46% | - |
| Work-home interference (yes) | 34% | - |
| Volunteer work (yes) | 39% | - |

**Financial factors**

| Financial situation | Short of money | Just adequate | Money left |
|---------------------|----------------|---------------|-----------|
|                     | 17%            | 25%           | 58%       |

MJH were predicted by health and mastery (being overweight), work characteristics (not having a permanent contract, having a part-time contract, not working in a medium-sized organisation, a poor social climate at work), work history (demotion in the past 12 months, a physically demanding job for more than 20 years), skills and knowledge (higher self-perceived ability to find a new employer in the coming 12 months), social factors (children living at home, participating in volunteer work), and financial factors (a poor household financial situation).

Transitions to hybrid MJH were predicted by demographics (high educational level), health and mastery (higher mastery), work characteristics (not having a permanent contract, higher emotional work demands, lower social support, absence of inappropriate behavior by customers), work history (short work history at current employer, no history of mental job demands or a history of more than 20 years in a mentally demanding job), social factors (work-home interference), and financial factors (a poor household financial situation).

Age and gender were not retained in either model 1A or 1B. This indicates that neither age nor gender contributed to the prediction of either combination MJH or hybrid MJH, independent from the predictors that were retained in the two models.
Factors that significantly predicted combination MJH did not significantly predict hybrid MJH in model 2B and vice versa, except for the number of years worked at current employer, contract type and household financial situation (Table 3). Several predictors were similarly associated, although not significantly, with both transitions (e.g. organisation size, social support at work, demotion, and years in a physically demanding job). Some predictors were distinctly associated with transitions to combination and hybrid MJH (e.g. body mass index (BMI), part-time work, work-home interference, and inappropriate behavior by customers).

Table 4 shows that both model 1A and 1B fit the data well. The C-statistic for model 1A decreased from 0.72 to 0.70 after internal validation indicating moderate discriminatory power. The C-statistic for model 1B decreased from 0.77 to 0.74 after internal validation. The explained variance (Nagelkerke R²) decreased from 12% to 9% after internal validation for model 1A and from 13% to 10% for model 1B. The shrinkage factor was similar for both models (model 1A: 0.91, and model 1B: 0.89).
Table 3. Multivariable associations between predictors and transitions to combination MJH and hybrid MJH

DISCUSSION

The first aim of this study was to identify the combination of predictors that best predicted transitions to combination MJH and hybrid MJH among older workers. We found that these transitions were best predicted by a combination of a wide variety of factors, including demographics, health and mastery, work characteristics, work history, skills and knowledge, social factors, and financial factors. The second aim was to explore whether or not the combination of predictors differ between combination MJH and hybrid MJH. We found that some factors predicted transitions to both combination MJH and hybrid MJH, i.e. not having a permanent contract and a poor household financial situation. Other factors only contributed to the prediction of one of these transitions. For instance, working part-time only predicted transitions to combination MJH and work-home interference only predicted hybrid MJH.

Although the present study only included employees over the age of 45, some of our findings are in line with studies including all age groups. For instance, in agreement with previous studies (9, 32, 33), we found that not having a permanent contract predicted combination MJH and hybrid MJH. This indicates that hedging and increasing income stability may be a reason for MJH among older employees. Previous research found that financial reasons are less important among older multiple job holders (2, 7). However, we found that, among older employees, a poor household financial situation did predict combination MJH and hybrid MJH. This suggests that financial reasons for MJH are important among older workers as well. Cross-sectional research in the Netherlands has shown that employees who have multiple jobs out of financial necessity score higher on a burnout scale than employees who have multiple jobs for other reasons (34). Therefore, it is important to further examine the association between reasons for MJH and its effects on health, since the results of such research could help prevent the negative health effects of MJH.

Previous research has shown that working part-time is a determinant of MJH (9, 32, 35). Because this is the first study that analyzed combination MJH and hybrid MJH separately, we were able to determine that working part-time only contributed to predicting combination MJH. Combined with the finding that work-home interference only predicted hybrid MJH, it appears that older employees are less likely to make transitions to hybrid MJH to increase work hours, but more likely to do so to improve work-life balance. This finding indicates that the hours-constraint hypothesis may be more applicable to combination MJH than hybrid MJH among older workers. Work-life imbalance has been associated with (job) exhaustion (36, 37), marital dissatisfaction (37-39), and depression (37). Older employees might be using hybrid MJH to reduce the negative effects of a work-life imbalance. Further research regarding the association between work-life imbalance, hybrid MJH and mental health is desirable.
Predictors of transitions to multiple job holding

Some candidate predictors that had not been studied earlier predicted transitions to combination MJH, hybrid MJH, or both. For instance, we found that both transitions were predicted by (distinct) job demands and job resource variables. A long history of high physical job demands and a poor social climate predicted transitions to combination MJH and higher emotional job demands and lower social support at work predicted transitions to hybrid MJH. MJH might enable older employees to combine jobs with heterogeneous demands and resources while retaining established privileges and rights in their primary job, which would be in line with the heterogeneous-jobs hypothesis. Combining jobs with heterogeneous demands and resources could positively affect health and work engagement (40, 41), which may enhance (sustainable) employability. Future research should study whether and how MJH can improve imbalances between job demands and job resources, and thereby contribute to sustainable employability.

To our knowledge, this is the first study to include health-related variables and mastery as potential predictors of MJH. This study showed that only BMI (combination MJH) and mastery (hybrid MJH) contributed to predicting transitions to MJH. Mastery has been associated with cognitive self-efficacy (42) and in turn with entrepreneurial intentions and activities (43). We found that higher self-efficacy, assessed as the self-perceived ability to find a new employer in the next 12 months, also predicted combination MJH.

The finding that other health-related variables did not contribute to the prediction of either combination MJH or hybrid MJH may be attributable to the healthy worker effect (44). Employees who have been able to continue working over the age of 45 are probably relatively healthy or able to adapt their work to their health situation. In both cases, health may not be a factor in the decision to hold multiple jobs. Alternatively, health may influence MJH via various mechanisms. On the one hand, employees with good health may be more likely to have multiple jobs as they have energy to cope with having more than one job. On the other hand, employees with poor health may also be more likely to have multiple jobs, as MJH may provide them with the flexibility needed to combine their health situation with (full-time) work while retaining established rights and privileges in their primary job.

One strength of this study is that we constructed prediction models, which enabled us to study a broad set of predictors. Our final models contained both predictors known to be related to MJH and predictors that had not been studied previously in relation to MJH. An additional strength is that we studied transitions to combination MJH and transitions to hybrid MJH separately, which to our knowledge has not been done before. This study also has limitations. First, the cohort may suffer from selection bias. STREAM participants are members of an internet panel. This may have caused an underrepresentation of groups with limited access to internet and in turn biased estimates (45). Response analyses of the baseline questionnaire
showed that persons aged 60-64 years and those with a low level of education participated slightly less often in STREAM. In addition, members of an internet panel may differ in other respects from the general population that were not measured. If these differences are related to predictors or outcomes, this may have affected our results. Second, because we excluded respondents who did not respond in all years, selective loss-to-follow-up may have resulted in bias. However, comparison of the respondents and non-respondents revealed few relevant differences. Third, employees who reported having two jobs at T2, T3 or T4 were identified as having made a transition to MJH. Therefore, the time period between the assessment of predictors and the outcomes varied from one to three years. However, we chose this design since little is known about the time between the occurrence of the various determinants and transitions to MJH. Fourth, the events per variable (EPV) ratio in multivariable backward selection was relatively low (4.9 for combination MJH and 3.2 for hybrid MJH) in light of the commonly used threshold of five to ten (46, 47). A low EPV can lead to biased regression coefficients. Internal validation was performed to estimate this bias, and resulted in shrinkage factors of approximately 0.9, thus indicating that bias was limited.

In conclusion, a wide variety of factors predicted transitions to combination MJH and hybrid MJH among older workers. Some factors predicted both combination MJH and hybrid MJH, e.g. not having a permanent contract and a poor household financial situation. Other factors only predicted combination MJH, e.g. working part-time, or hybrid MJH, e.g. work-home interference. This suggests that distinct mechanisms may underlie transitions to combination MJH and hybrid MJH. Further, the present study added to our knowledge that some factors that had not been previously studied predicted MJH, e.g. self-efficacy and job demands and resources. These insights can be used to formulate new hypotheses regarding determinants of and reasons for MJH.

The results of this study show which factors form the best combination of predictors of combination MJH and hybrid MJH among older workers but do not imply that there is a causal relation between individual predictors and combination MJH and/or hybrid MJH. Future etiologic studies should examine which of the predictors we found are also individually and causally related to MJH and by which mechanisms.

Authors’ contributions
SB participated in the design of the research question and the methods and analyzed the data. He drafted the manuscript and approved the final version for publication. GAG, CRLB, and AJB also participated in the design of the research question and the methods used, provided critical feedback on the manuscript and approved the final version for publication. PMB provided critical feedback on the manuscript and approved the final version for publication.
Funding
The data collection was partly funded by the Dutch Ministry of Social Affairs and Employment. As the funding was not provided in the form of a grant, there is no grant number.

Ethics approval and informed consent
The work was performed at the Department of Public and Occupational Health, the Amsterdam Public Health research institute, VU University Medical Center, Amsterdam, The Netherlands, and Netherlands Organisation for Applied Scientific Research TNO, Leiden, The Netherlands. The medical ethics committee of the VU university medical center declared that the collection of the data used in this study was not subjected to the Medical Research Involving Human Subjects.

Disclosure (authors)
The authors declare no conflicts of interest.

Disclosure by ajim editor of record
Paul Landsbergis declares that he has no conflict of interest in the review and publication decision regarding this article.
