ABSTRACT

Long noncoding RNAs (LncRNAs) act as crucial regulators in various cancers including osteosarcoma (OS), yet their potential roles and molecular mechanisms in OS chemoresistance remain unclear. In the present study, we investigated the role and potential regulatory mechanism of the most down-regulated expressed lncRNA, FENDRR screened by our previous lncRNA microarray analysis between the paired doxorubicin-resistant and sensitive human osteosarcoma cell lines (MG63/DXR vs MG63). FENDRR expression was down-regulated in the doxorubicin-resistant OS cell lines and tissues and negatively correlated to the poor prognosis of OS patients. Overexpression of FENDRR suppressed doxorubicin-resistance, G2/M phase of cell cycle, and promoted cell apoptosis of osteosarcoma cells in vitro and tumor growth in vivo whereas FENDRR knockdown had the opposite effects. In addition, we found that FENDRR was mainly located in the cytoplasm and could regulate the drug resistance of osteosarcoma cells by negatively affecting posttranscriptional expression of ABCB1 and ABCC1. Together, our study demonstrated that lncRNA FENDRR may act as an inhibitory molecule of doxorubicin-resistance through down-regulating the expression of ABCB1 and ABCC1 genes in osteosarcoma cells. These findings may extend the function of FENDRR in tumor progression and provide a novel target for reversing OS chemoresistance.

INTRODUCTION

Osteosarcoma (OS) is the most common type of solid bone tumors in children and adolescence, which is aggressive, high-grade, with lung metastases in about 20% patients at first diagnosis [1]. Although the systemic therapy including neoadjuvant chemotherapy and surgical excision has raised the 5-year survival rate of OS patients to about 70% within the past decades, the occurrence of intrinsic or acquired drug-resistance has greatly hindered the survival rate with further improvement [2, 3]. Moreover, there is no established second-line chemotherapy for OS patients who are resistant to the commonly used chemotherapeutics including doxorubicin, cisplatin, methotrexate, and ifosfamide [4, 5]. Thus, it is crucial to understand the molecular mechanisms underlying OS chemoresistance to develop more effective treatments against this disease [6].

Long noncoding RNA (lncRNA) is a type of non-protein coding RNA transcripts longer than 200 nucleotides [7]. Rapidly accumulating evidence has demonstrated that lncRNAs could play important roles in a variety of cellular physiological and pathologic processes, including cell proliferation, apoptosis, autophagy, invasion, metastasis, chemoresistance, radioresistance and so on [8, 9]. Actually, several lncRNAs including H19 [10, 11], MALAT1 [12, 13], UCA1 [14, 15], HOTTIP [16], have been reported to be involved in the chemoresistance of various kinds of malignant tumors, such as bladder cancer, pancreatic cancer, glioblastoma, and so on. However, the expression and specific role of lncRNA in OS chemoresistance have not been well understood.

In the present study, we identified the function and regulatory mechanism of lncRNA FENDRR in OS doxorubicin-resistance, which was screened in our...
previous study on the lncRNA and mRNA expression profiles of the doxorubicin-resistant human OS cell line MG63/DXR and its parental cell line MG63 ascertained by microarray analysis [17]. We found that lncRNA FENDRR was the most down-regulated lncRNA in the doxorubicin-resistant osteosarcoma cells and possibly acted as a drug-resistance suppressing molecule through inhibiting ABCB1 and ABCC1 expression. Besides, our data demonstrated that FENDRR could act as a biomarker to predict the chemotherapy sensitivity and prognosis of OS patients. Thus, these results elucidated a novel role for FENDRR in reducing OS chemoresistance and suggested a potential target to sensitize doxorubicin-resistance in OS.

RESULTS

LncRNA FENDRR was down-regulated in the doxorubicin-resistant osteosarcoma cell lines and tissues verified by microarray and qPCR

In our previous study, LncRNA microarray was conducted in three pairs of doxorubicin-resistant human osteosarcoma cell line MG63/DXR and its parental cell line MG63 to identify the candidate lncRNAs involved in the OS chemoresistance [17]. Among the 3,465 differently expressed lncRNAs, 1,704 lncRNAs were down-regulated more than 2-fold change in the MG63/DXR cells relative to MG63 and lncRNA FENDRR was the most down-regulated of 22-fold change, which was selected as a candidate for further examination via RT-qPCR (Figure 1A). To further validate the results of microarray, we analyzed FENDRR expression in three paired doxorubicin-resistant and sensitive human osteosarcoma cell lines (MG63/DXR vs MG63, KH-OS/DXR vs KH-OS, U2-OS/DXR vs U2-OS) and other two doxorubicin -sensitive osteosarcoma cell lines (SaoS2 and HOS) by qRT-PCR and the results showed that FENDRR expression was significantly desregulated with a dramatically suppressed expression in the doxorubicin-resistant cell lines compared with the doxorubicin-sensitive cell lines (Figure 1B). We also evaluated the expression level of FENDRR in 80 osteosarcoma tissues that were divided in the chemoresistant group (N = 40) and chemosensitive group (N = 40). FENDRR was significantly down-regulated in tumor tissues resected from the multidrug resistant osteosarcoma patients and up-regulated in the multidrug sensitive patients in accordance with the above findings (Figure 1C, P < 0.001). We further examined whether FENDRR expression correlated with osteosarcoma prognosis. Kaplan-Meier survival analysis showed that patients with low FENDRR expression had a lower rate of overall life compared with the high FENDRR expression (Figure 1D, p < 0.01, log-rank test). These results suggested that lncRNA FENDRR was possibly related to the occurrence of chemoresistance and to predict the chemoresponse and prognosis of OS patients.

FENDRR increased doxorubicin sensitivity of osteosarcoma cells in vitro

To further identify the role of lncRNA FENDRR in OS chemoresistance, CCK-8 assay and colony formation analysis were performed to examine the effect of FENDRR on cell sensitivity and proliferation to anticancer drugs of doxorubicin in the MG63 (or KH-OS) and MG63/DXR (or KH-OS/DXR) cells. MG63/DXR (or KH-OS/DXR) cells were transfected with the FENDRR expression vector or empty vector. MG63 (or KH-OS) cells were stably transfected FENDRR-specific siRNA and control siRNA served as a negative control (NC). Satisfactory transfection efficiency was obtained at 48 h post-transfection and confirmed by qPCR (Figure 2A and 2B). IC50 values for doxorubicin in response to FENDRR up-or down-regulation were measured. The results showed that compared with MG63/DXR (or KH-OS/DXR) cells transfected with empty vector, the IC50 values of doxorubicin in MG63/DXR (or KH-OS/DXR) cells transfected with FENDRR were reduced by 50.5% (or 37.5%) (P < 0.01, P < 0.01, Figure 2C). Compared with MG63 (or KH-OS) cells transfected with si-NC, the IC50 values of doxorubicin in MG63 (or KH-OS) transfected with si-FENDRR were increased by 150% (or 120%) (P < 0.01, P < 0.01, Figure 2D).

Similarly, colony formation assays revealed that cell proliferation was significantly suppressed in FENDRR-overexpressing MG63/DXR (or KH-OS/DXR) cells compared with empty vector transfected cells exposed to 16 μg/mL doxorubicin for 14 days (P < 0.01, P < 0.01, Figure 2E). Cell proliferation was significantly increased in FENDRR-down-regulated MG63 (or KH-OS) cells compared with NC-transfected cells exposed to 4 μg/mL doxorubicin for two weeks (P < 0.01, P < 0.01, Figure 2F). Taken together, these data suggested that FENDRR might resensitize OS cells to doxorubicin in vitro.

FENDRR suppressed cell cycle and promoted apoptosis of osteosarcoma cells

Furthermore, we used flow cytometry analyses to assess the effect of FENDRR on cell cycle and apoptosis. The rates of G0/G1 and S phases were more than in the forced expression of FENDRR of MG63/DXR (or KH-OS/DXR) cells compared with the vector transfected cells whereas FENDRR knockdown in the MG63 (or KH-OS) cells significantly increased the rate of G2/M phase relative to the si-NC group (Figure 3A and 3B). In addition, compared with negative controls, overexpression of FENDRR resulted in increased apoptosis proportion of MG63/DXR (or KH-OS/DXR) cells when exposed to doxorubicin (0 μg/mL or 8 μg/mL) for 48 h (Figure 3C).

Likewise, down-regulation of FENDRR caused a decrease in apoptosis proportion of MG63 (or KH-OS) cells
compared with the si-NC group treated with doxorubicin (0 μg/mL or 4 μg/mL) for 48 h (Figure 3D).

**Overexpression of FENDRR improves the *vivo* sensitivity of osteosarcoma cells to doxorubicin**

To further assess the underlying effect of FENDRR in suppressing the chemoresistance of osteosarcoma cells to doxorubicin *in vivo*, we inoculated nude mice with MG63/DXR cells stably transfected with FENDRR expression vector or empty vector or MG63 cells transfected with si-FENDRR or si-NC. These cells were subcutaneously injected into mice followed by treatment with doxorubicin after tumor formation (50 mm³). As shown in the figure, tumors derived from pcDNA-FENDRR-transfected MG63/DXR cells grew significantly slower than those derived from si-NC (Figure 3E).

---

**Figure 1: LncRNA FENDRR was down-regulated in the doxorubicin-resistant osteosarcoma cell lines and tissues verified by microarray and qPCR.** (A) Heat maps showed that the profiles of twenty most-differentially expressed lncRNAs determined using microarray, in doxorubicin-resistant MG63/DXR cells than that in their parental doxorubicin-sensitive MG63 cells. Red represents high expression levels and green represents low expression levels. Of them, NR_036444 (also named as FENDRR) was the most down-regulated lncRNA of 22-fold change. (B) FENDRR expression was significantly decreased in doxorubicin-resistant osteosarcoma cells compared with doxorubicin-sensitive osteosarcoma cells by qRT-PCR validation. (C) The expression level of FENDRR was detected in 40 pairs of osteosarcoma tissues by qRT-PCR. FENDRR expression level in specimens of OS patients with good chemoresponse was about 2.5 fold higher than those with poor chemoresponse. (D) Patients with low levels of FENDRR expression demonstrated reduced average survival than the patients with high expression. *P < 0.05; **P < 0.01.
Figure 2: FENDRR increased doxorubicin sensitivity of osteosarcoma cells in vitro. (A) RT–qPCR analysis of the effect on overexpression of FENDRR by vector transfection in the MG63/DXR and KH-OS/DXR cell lines. (B) RT–qPCR analysis of the effect on knockdown of FENDRR expression by siRNA in the MG63 and KH-OS cell lines. si-FENRR-1 was chosen for the siRNA used in the study because of the highest knockdown efficiency. (C) Cell sensitivity of osteosarcoma cells to doxorubicin was evaluated using the CCK-8 assay upon exposure to the step-up concentration of doxorubicin for 48 h. Cell viability and IC50 value of MG63/DXR (KH-OS/DXR) cells in the groups transfected with FENDRR were reduced compared with the control groups transfected with empty vector. (D) Cell viability and IC50 value of MG63 (KH-OS) cells in the si-FENDRR group were increased compared with the si-NC groups. (E) Cell proliferation in response to anticancer drugs was examined using colony formation analysis. Cell colony formation in the FENDRR group of MG63/DXR (KH-OS/DXR) cells was reduced compared with the FENDRR-NC group when exposed to 16 ug/ml doxorubicin for 14 days. (F) Cell colony formation in the si-FENDRR group of MG63 (KH-OS) cells was increased compared with the si-NC group when exposed to 4 ug/ml doxorubicin for two weeks. *P < 0.05; **P < 0.01.
slower than those from controls following doxorubicin treatment. However, tumors formed from si-FENDRR transfected MG63 cells grew faster compared with those derived from si-NC transfected cells after doxorubicin exposure (Figure 4A). Mice were sacrificed after 5 weeks for drug injection. Growth curves of tumor volumes and nude mice weight indicated that si-FENDRR-treated group increased significantly and FENDRR transfected group decreased markedly (Figure 4B and 4C). Together, these data suggested that dysregulated lncRNA FENDRR might be associated with the doxorubicin–resistance of osteosarcoma cells in vivo.

**FENDRR was mainly located in the cytoplasm and regulated the expression of the classical drug resistance related genes of ABCB1 and ABCC1**

To examine the subcellular localization of FENDRR, Cy3-labeled probes specific for FENDRR were used for RNA-FISH. This analysis confirmed FENDRR-specific staining was observed in the cytoplasm of MG63 and KH-OS cells, whereas nearly no staining was observed in the nucleus, indicating that FENDRR was predominantly localized in the cytoplasm (Figure 5A). Then RT–qPCR of nuclear and cytoplasmic fractions of the two cells further validated that FENDRR was mainly located in the cytoplasm (Figure 5B), indicating its role of regulating the gene expression at the posttranscriptional level.

To clarify the underlying mechanism of lncRNA FENDRR regulating chemoresistance in OS, we further conducted bioinformatics analysis and co-expression network analysis among FENDRR and the reported multidrug resistance-related genes. GO and Pathway analysis were performed among the FENDRR related differently expressed genes and the results of GO analysis revealed that these dysregulated transcripts were associated with oxidation-reduction process (ontology: biological process), mitochondrion (ontology: cellular component) and protein binding (ontology: molecular function) (Figure 5C). Pathway analysis based on the KEGG database showed that 20 pathways were significantly enriched among the dys-regulated mRNAs, including the “PI3K-Akt signaling pathway” and “NF-kappa B signaling pathway” that have been previously reported to be involved in the osteosarcoma chemoresistance. (Figure 5D). Actually, there have been few lncRNAs reported to be involved in the osteosarcoma chemoresistance. We first identified the lncRNA expression profiles of the doxorubicin-resistant human osteosarcoma cell line MG63/DXR and its parental cell line MG63 by microarray analysis [17] and found that lncRNA ODRUL was the most up-regulated of 20-fold change in the doxorubicin-resistant OS cell lines, promoted doxorubicin resistance in OS by increasing the expression of transcription factor FOXC2 through a RNA-RNA double-strand structure in the overlapping region, further facilitating ABCB1 expression [28, 29]. Besides, Wang Y et al reported that lncRNA LINC00161 sensitizes osteosarcoma cells to cisplatin-induced apoptosis by regulating the miR-645-IFIT2 axis[30]. Zhou Q et al found that lncRNA PVT1 promotes osteosarcoma development by acting as a molecular sponge to regulate miR-195 [32].

**DISCUSSION**

Osteosarcoma is a high-grade malignant bone tumor [18]. Although the introduction of chemotherapy has greatly improved the survival rate of OS patients, the clinical effectiveness is limited by the occurrence of multi-drug resistance, which ultimately leads to poor prognosis [19]. Recently, many IncRNAs have been demonstrated to regulate chemoresistance in various kinds of cancers through affecting the cell cycle, cell apoptosis or some related drug-resistant genes or signal transduction pathways [20–24]. For example, Si X et al reported that lncRNA H19 confers chemoresistance in ERα-positive breast cancer through epigenetic silencing of the pro-apoptotic gene BIK [10]. Chen J et al found that lncRNA CCAT1 acts as an oncogene and promotes chemoresistance in docetaxel-resistant lung adenocarcinoma cells through sponging let-7c and further up-regulating Bcl-xl [25]. Li Z et al reported that lncRNA HOTTIP promotes progression and gemcitabine resistance by regulating HOXA13 in pancreatic cancer [16]. Shen et al reported that lncRNA PVT1 epigenetically silences miR-195 and modulates EMT and chemoresistance in cervical cancer cells[26]. Özeş AR et al found that NF-κB-HOTAIR axis links DNA damage response, chemoresistance and cellular senescence in ovarian cancer [27].

In the current study, we focused on the function and mechanism of another lncRNA, FENDRR, also screened by our microarray analysis previously described.
Figure 3: FENDRR suppressed cell cycle and promoted apoptosis of osteosarcoma cells. (A) The rates of G0/G1 and S phases were more than in the forced expression of FENDRR of MG63/DXR (or KH-OS/DXR) cells compared with the empty vector transfected cells. (B) FENDRR knockdown in the MG63 (or KH-OS) cells significantly increased the rates of G2/M phase relative to the si-NC group. (C) Compared with negative controls, overexpression of FENDRR resulted in increased apoptosis and decreased surviving proportion of MG63/DXR (or KH-OS/DXR) cells when exposed to doxorubicin (0 μg/mL or 8 μg/mL) for 48 h. (D) Down-regulation of FENDRR caused a decrease in apoptosis and increased surviving proportion of MG63 (or KH-OS) cells compared with the si-NC group treated with doxorubicin (0 μg/mL or 4 μg/mL) for 48 h *P < 0.05.
As is known to us, FENDRR is located at chr3q13.31, divergently transcribed from the FOXF1 promoter and co-expressed with FOXF1 [33]. Grote et al first identified that Fendrr, homologous to FENDRR in human, is essential for proper heart and body wall development in mouse and it could bind to both polycomb repressive complex 2 (PRC2) and Trithorax group/MLL protein complexes (TrxG/MLL), which play pivotal roles in the control of chromatin structure and gene activity [33]. He further found that Fendrr functions in the lateral mesoderm via epigenetic modification of regulatory elements, thereby adjusting the expression level of target genes in this tissue and setting long-term marks, which allow for the proper control of Fendrr target genes in the descendants of lateral mesoderm cells [34]. Besides, Szafranski reported that FENDRR was expressed in the lung, and associated with a lethal lung developmental disorder called ACD/MPV (alveolar capillary dysplasia with misalignment of pulmonary veins) [34,35]. Apart from its involvement in the heart and body wall or mesoderm development, its role in tumor progression also has been identified in the gastric cancer and non-small cell lung cancer. Xu et al reported that lncRNA FENDRR was down-regulated in gastric cancer cell lines and cancerous tissues and low FENDRR expression predicted poor prognosis. Histone deacetylation was involved in the down-regulation of FENDRR in gastric cancer cells and FENDRR overexpression suppressed invasion and migration by down-regulating FN1 and MMP2/MMP9 expression [36]. Besides, lncRNA FENDRR, also named as lncRNA FOXF1-AS1, was an intergenic lncRNA, next to the FOXF1 gene in the genome location. Miao et al found that loss of lncRNA FOXF1-AS1 regulates epithelial-mesenchymal transition, stemness and metastasis of non-small cell lung cancer cells via EZH2 and down-regulation of FOXF1 [37].

However, there has been seldom report about the FENDRR and osteosarcoma or chemoresistance. In the study, we first identified that FENDRR was consistently down-regulated in the doxorubicin-resistant OS cell lines and tissues and negatively correlated with poor prognosis of OS patients. Functional analysis revealed that overexpression of FENDRR suppressed doxorubicin resistance, G2/M phase of cell cycle, and promoted cell apoptosis of osteosarcoma cells in vitro and tumor growth in vivo whereas FENDRR knockdown had the opposite effects. These results suggested that IncRNA FENDRR may functions as a suppressor in the OS chemoresistance.

As is known to us, the most classical and important molecular mechanism of multidrug resistance in cancer is dysregulation of ABC membrane transporters [38–42]. ABCB1, also named MDR1, is a well-known multidrug resistance-associated gene and P-glycoprotein (P-gp), the protein encoded by ABCB1, is an ATP-dependent

Figure 4: Overexpression of FENDRR improves the \textit{vivo} sensitivity of osteosarcoma cells to doxorubicin. (A) General conditions of nude mice in the four groups when exposed to the same treatment. The nude mice were sacrificed in the 7th week. The volumes of transplanted tumors were smaller in the FENDRR group when compared with the FENDRR-NC group, whereas larger in the si-FENDRR group relative to the si-NC group. (B) Tumors formed in the FENDRR group grew slower compared with the FENDRR-NC group, whereas faster in the si-FENDRR group relative to the si-NC group. (C) Weights of nude mice were smaller in the FENDRR group relative to the FENDRR-NC group, whereas larger in the si-FENDRR group when compared with the si-NC group *$P < 0.05$. 
Figure 5: FENDRR was mainly located in the cytoplasm and regulated the expression of the classical drug resistance related genes ABCB1 and ABCC1. (A) Subcellular localization of FENDRR by RNA-FISH in the MG63 and KH-OS cells. Nuclei was stained blue (DAPI) and FENDRR was stained red. (B) Nuclear and cytoplasmic fractions assay further validated the subcellular localization of FENDRR in the MG63 and KH-OS cells. (C) GO analysis of the mRNAs related to the lncRNA FENDRR. The Gene Ontology project provided a controlled vocabulary to describe gene and gene product attributes in any organism. The ontology covered three domains: Biological Process, Cellular Component and Molecular Function. (D) Pathway analysis showed that 20 pathways were significantly enriched among the dys-regulated mRNAs related to the lncRNA FENDRR, including the “PI3K-Akt signaling pathway” and “NF-kappa B signaling pathway”. (E) The mRNA level of ABCB1, ABCC1, ABCC3, EGFR and IL-6. (F) The protein level of ABCB1, ABCC1, ABCC3, EGFR and IL-6. Obviously, the expression of ABCB1 and ABCC1 other than EGFR, IL-6 and ABCC3 greatly decreased in the FENDRR overexpression group and significantly increased in the FENDRR knockdown group relative to the NC groups as confirmed by both PCR and WB detection.*p < 0.05.
drug efflux pump (especially for xenobiotic compounds) with broad substrate specificity, leading to resistance to anticancer drugs[43]. Besides, ABC1, also named MRP1, involved in P-gp up-regulation and contributed to mediate drug resistance [44, 45]. In fact, several reports have identified that lncRNA could regulate the chemoresistance by influencing the expression of ABCB1 or ABC1. Wang et al found that lncRNA MRUL, located 400kb downstream of ABCB1, was significantly up-regulated in two multidrug-resistant GC cell lines and MRUL might positively affect the expression of ABCB1 in an orientation- and position-independent manner [28,46]. Xiao et al showed that lncRNA UCA1 functions as a competitive endogenous (ceRNA) of ABCB1 through completely binding the common miR-16 in chronic myeloid leukemia cells [47]. Moreover, Zhang et al reported that lncRNA PVT1 could promote the development of MDR through regulation of mTOR/HIF-1α/P-gp and ABC1 signaling pathway in gastric cancer cells [48].

In our present study, we found that the expression of FENDRR and ABCB1 or ABC1 was significantly negatively correlated through the bioinformatics analysis. Further validation by PCR and WB found that FENDRR could negatively regulate the mRNA and protein of ABCB1 and ABC1 instead of the other genes, such as ABC1, EGFR or IL-6. On basis of the previously reported mechanism of FENDRR in regulating gene expression, it may promote the expression of ABCB1 and ABC1 through binding PRC2 to epigenetically modify the gene promoters. However, the specific regulatory mechanism between lncRNA FENDRR and the two drug-resistance related genes needed to be further studied by RNA Pull down and chromatin immunoprecipitation.

In summary, our study showed that FENDRR is dramatically down-regulated in the doxorubicin-resistant OS cell lines and tissues and negatively correlated with poor prognosis of OS patients. Moreover, overexpression of FENDRR has the effect of suppressing doxorubicin resistance, G2/M phase of cell cycle, and promoted cell apoptosis of osteosarcoma cells in vitro and tumor growth in vivo. Then lncRNA FENDRR possibly acts as an inhibitory molecule in the OS chemoresistance by down-regulating the posttranscriptional expression of the classical multidrug resistance-related ABCB1 and ABC1 genes. Our results demonstrated an important lncRNA involved in OS chemoresistance, thereby providing a promising option for facilitating the development of chemotherapy.

MATERIALS AND METHODS

Cell lines and culture conditions

MG63, SaoS2 and HOS human osteosarcoma cell lines (American Type Culture Collection (ATCC)) were cultured in DMEM (Gibco, Cat. No. 12491-015, CA, USA) supplemented with 10% fetal bovine serum (Gibco, Gran Island, NY, USA). The doxorubicin-resistant osteosarcoma cell line MG63/DXR, which was kindly provided by Dr. Yoshiho Oda [49] (Kyushu University, Fukuoka, Japan), was generated in a stepwise manner by exposing drug-sensitive MG63 cells to increasing doses of doxorubicin (DXR). The paired KH-OS and KH-OS/DXR were kindly donated by Dr. Duan ZF [51] (Massachusetts General Hospital, Boston, USA) and generated by the same method. The surviving cells were subsequently maintained in the conditioned medium with 1 μg/mL DXR (Sigma) to retain its drug-resistant phenotype.

Clinical samples and histological response evaluation

A total 80 of patient’s specimens used in this study were described in our previous study. Written informed consent was obtained from all patients at the Shanghai Tenth Hospital between 2006 and 2015. The clinical parameters of osteosarcoma patients in this study are presented in Table 1.

Plasmid construction and cell transfection

The synthetic FENDRR sequence (2693bp) was subcloned into the pcDNA3.1 vector (Invitrogen). FENDRR ectopic expression was achieved through pcDNA3.1-FENDRR transfection using Lipofectamine 2000 (Invitrogen) according to the manufacturer’s instructions, and an empty pcDNA3.1 vector was used as a control. si-FENDRR and si-NC were purchased from GenePharm (Shanghai, China) and transfected into MG63/DXR (or KH-OS/DXR) cells using Lipofectamine 2000 (Invitrogen) according to the manufacturer’s instructions, and an empty pcDNA3.1 vector was used as a control. Three siRNA sequences were designed for the FENDRR. The sequence of si-FENDRR-1 was 5′-GGAGGGAATTAGAAGCGTTT-3′, si-FENDRR-2 was 5′-GCATTTCAGGGCCAGCCTA-3′, si-FENDRR-3 was 5′-GCACGTAGCCATTGTGAAT-3′ (si-FENDRR-1 has the highest inhibition efficiency and si-FENDRR mentioned in the article refers to si-FENDRR-1) and the relative si-NC sequence was 5′-TTCTCCGAACGTGTCACGT-3′.

Drug-resistance assay

In vitro drug cytotoxicity was measured by Cell Counting Kit-8 (CCK-8) assays. The cells incubated without drugs were set at 100% survival and were used to calculate the concentration of each cytostatic drug lethal to 50% of the cells (IC50). The ranges of drug concentrations were based on earlier studies and aimed at obtaining an IC50 value for all cases. Doxorubicin was obtained...
from commercial sources and dissolved according to the manufacturer’s instructions. After 48 h of transfection in 96-well plates, freshly prepared medium containing several final concentrations of doxorubicin (0, 2, 4, 8, 16, 32 and 64 μg/mL) was added to the wells, with three replicate wells for each concentration. After incubation for an additional 48 h, cell viability was measured using Cell Counting Kit-8 (CCK-8, Dojindo, Japan), according to the manufacturer’s instructions.

### Colony formation assay

MG63 and KH-OS cells (500 cells per well) were seeded in a six-well plate and cultured for 14 days after treatment. Colonies were then fixed with 10% formaldehyde for 10 min and stained for 5 min with 0.5% crystal violet. The number of visible colonies was counted manually.

### RNA extraction and qRT-PCR

Total RNA from all tissues and cells was isolated using Trizol reagent. The relative gene expression was calculated by using 2−ΔΔCt method. Primers used for amplifying specific genes in this study are presented in Table 2.

### Cell cycle and apoptosis analysis

Cells for cell cycle analysis were stained with propidium iodide using the BD Cycle test plus DNA Reagent Kit (BD Biosciences). Cells for apoptotic analysis were double-stained with Annexin V-FITC and propidium iodide, 48 h after the transfection and were analyzed using a flow cytometer (BD Biosciences) equipped with Cell Quest software (BD Biosciences). The methods used in this assay have been described previously [28].

### RNA-fluorescence in situ hybridization (FISH)

Cy3-labeled FENDRR and DAPI-labeled U6 probes were obtained from Gene Pharma (Shanghai, China). RNA FISH were performed using fluorescent in situ hybridization kit according to the manufacturer’s protocol (Thermo Fischer).

### Cell cytoplasm/nucleus fraction isolation

Nuclear and Cytoplasmic Extraction Reagents (Thermo Scientific, USA) were employed to prepare cytoplasmic and nuclear extracts from MG63 and KH-OS cells. RNAs extracted from each of the fractions were subjected to following RT–qPCR analysis to demonstrate the levels of nuclear control transcript (β-actin), cytoplasmic control transcript (U6), and IncRNA FENDRR.

### In vivo tumor xenograft model

BALB/c nude mice (4 weeks old, 8-10g, female) were maintained under pathogen free conditions and all procedures for the mouse experiments were approved by the Animal Experimental Ethics Committee of Shanghai Tenth Hospital. Mice were divided into four groups according to the completely randomized method (N = 5/group). Approximately 1.0*10^7 MG63/DXR cells stably transfected with pcDNA3.1-FENDRR or pcDNA3.1-vector and MG63 cells transfected with si-FENDRR or si-NC were respectively injected subcutaneously into the right side of the posterior flank of nude mice in the four groups (Department of Central Laboratory, Department of Nuclear Medicine, Department of Pathology, and Department of Tumor Biology, Shanghai Tenth Hospital).
Shanghai Tenth Hospital). Tumor growth was examined every other day with a vernier caliper and nude mice weights were also documented simultaneously. Tumor volumes were calculated using the equation: \( V = A \times B^2 / 2 \) (mm\(^3\)), where A is the largest diameter, and B is the perpendicular diameter. When the average tumor size reached approximately 50 mm\(^3\), 5.0 mg/kg doxorubicin was administered through tail vein injection every other day. After 5 weeks for drug injection, all mice were killed, necropsies were performed, and tumors were excised. Intratumoral injection of Ad-si-FENDRR (2 × 10\(^9\) plaque-forming units [PFU]) or Ad-si-NC was performed. Mice were photographed before sacrifice with an IVIS\(^{\text{TM}}\) Lumina II system (Caliper Life Sciences, Hopkinton, MA) beginning 10 minutes after an intratumoral injection of 4.0 mg of luciferin (Gold Biotechnology, Inc., St. Louis, MO) in 100 \( \mu \)L of saline.

**Western blot analysis**

Protein samples were separated on SDS-PAGE gels and transferred to PVDF membranes (Bio-Rad). PVDF membranes were incubated with primary antibody, then incubated with horseradish peroxidase conjugated secondary antibody. After washing 3 times for 10 min in TBST, the proteins were visualized with an ECL detection system. ImageJ software (BD, Franklin Lakes, NJ, USA) was used to quantify the level of protein expression by calculating integrated density value (IDV) using GAPDH as a control. Antibodies against ABCB1, ABCC1, ABCC3, EGFR, or IL-6 were purchased from Cell Signaling Technology (Danvers, MA, USA).

**Bioinformatics analysis**

GO analysis was applied to analyze the main functions of the different expression genes related to the FENDRR according to the GO database (www.geneontology.org). Pathway analysis was used to find out the significant pathways of the different genes related to the FENDRR according to KEGG database (Kyoto Encyclopedia of Genes and Genomes, www.genome.jp/kegg). Co-expressed analysis was conducted between lncRNA FENDRR and its related coding genes with Pearson correlation coefficients equal to or greater than 0.999. The correlation coefficients of FENDRR and the multi-drug resistance genes were shown in the Table 3.

**Statistics**

All statistical analyses were performed using SPSS 22.0 software (IBM). Data are expressed as the Mean ± SD for at least three independent experiments. Differences between groups were analyzed using the Student’s t test or one-way ANOVA when more than two groups were compared. Overall survival was calculated by Kaplan-Meier survival analysis and compared using the log-rank test. A value of \( P < 0.05 \) was considered statistically significant.

Table 2: Primers used for PCR validation

| Gene              | Forward and Reverse primer                                      |
|-------------------|----------------------------------------------------------------|
| NR_036444 (FENDRR) | F: 5′ CTCCGTCAAGAGTCTCCAGAG 3′  \n|                   | R: 5′ GCCTCAACAGCAGAAACAT 3′                                  |
| ABCB1             | F: 5′ TTGGACAGAAAGGCGAAGCAG 3′  \n|                   | R: 5′ TCAGCATTACGAACGATGACC 3′                                |
| ABCC1             | F: 5′ CTACCTCCTGCGGCTGATTCTGCT 3′  \n|                   | R: 5′ CATCGGTTACGGGATTGTCT 3′                                 |
| ABCC3             | F: 5′ CCTCATCCTCCTGTGCAACGACAG 3′  \n|                   | R: 5′ CAGCTTAAACACTTGGATCCGATC 3′                            |
| EGFR              | F: 5′ GCCCAAGATCCCCATCATTGC 3′  \n|                   | R: 5′ CTGTACACTTGCCGAAATGC 3′                                |
| IL-6              | F: 5′ AAAGGGACCTGGCAGAAA 3′  \n|                   | R: 5′ AGCTCTGCTTGGTCATTCAC 3′                                |
| GAPDH             | F: 5′ CATGAGAAGTATGCAACAGCCT 3′  \n|                   | R: 5′ AGTCTTCCCACGATACAAAGT 3′                              |

**Table 3: Correlation coefficient of lncRNA FENDRR and ABCB1, ABCC1, ABCC3, EGFR, IL-6**

| Seqname          | Drug-resistance associated Genes |
|------------------|---------------------------------|
| NR-036444(FENDRR)| ABCB1  –0.997  \n|                  | ABCC1  –0.998  \n|                  | ABCC3  –0.996  \n|                  | EGFR  –0.998  \n|                  | IL-6  –0.998  |

as a control.
ACKNOWLEDGMENTS AND FUNDING

This project was supported by a Grant from the National Natural Science Foundation of China (No.81572630), Shanghai Pujiang Program of Shanghai Science and Technology Commission (NO.13PJJD023) and Shanghai Jiaotong University Medical-Engineering Cross Research Fund (NO.YG2012MS49).
