Our previous study showed that interferon gamma (IFN-γ) might enhance the immunosuppressive properties of mesenchymal stem cells (MSCs) by upregulating the expression of indoleamine 2,3-dioxygenase. Therefore, we treated experimental autoimmune encephalomyelitis (EAE) mice, an animal model of multiple sclerosis (MS), with IFN-γ-primed human umbilical cord MSCs (IFN-γ-hUCMSCs). This study aimed to investigate the potential therapeutic effects of IFN-γ-hUCMSCs transplantation and to identify the biological pathways involved in EAE mice. Firstly, the body weights and clinical scores of EAE mice were recorded before and after treatment. Then, the inflammatory cytokine levels in splenic cell supernatants were quantified by enzyme-linked immunosorbent assay. Finally, the mRNA expression levels of signal transducer and activator of transduction 3 (STAT3), retinoic acid-related orphan receptor gamma t (ROR-γt), and forkhead box P3 (Foxp3) were detected by quantitative reverse transcription polymerase chain reaction. We observed that IFN-γ-hUCMSCs transplantation significantly alleviated body weight loss and decreased the clinical scores of mice. Additionally, IFN-γ-hUCMSCs transplantation could regulate the production of inflammatory cytokines, interleukin (IL)-10 and IL-17, thereby showing more potent treatment efficacy than human umbilical cord MSCs (hUCMSCs) transplantation. Compared with the EAE group, the expressions of STAT3 and ROR-γt in the transplantation groups were significantly decreased, but the expression of Foxp3 was significantly upregulated in the IFN-γ-hUCMSCs transplantation group compared to that in the hUCMSCs transplantation group. We assumed that IFN-γ-hUCMSCs may affect the balance of T helper 17 (Th17) cells/regulatory T cells (Tregs) through the Foxp3/ROR-γt/STAT3 signaling pathway to reduce the inflammatory response, thereby improving the clinical symptoms of EAE mice.
INTRODUCTION

Multiple sclerosis (MS) is a common cause of neurological disability among young people, resulting in increased economic and social costs (1, 2). MS has been investigated over a century, and although much has been discovered about the immunobiology, genetics, and epidemiology of this disease, the treatment outcomes remain unsatisfactory.

MS is characterized by inflammation-mediated demyelination of the white matter tracts with partial preservation of axons (3). Experimental autoimmune encephalomyelitis (EAE) is an animal model of MS that is particularly useful for testing new therapeutic approaches against MS (4, 5). Studies indicated that T helper (Th) cells, mainly Th1 and Th17 cells, which are characterized by the production of interleukin (IL)-17, are involved in the pathogenicity of MS and EAE, whereas regulatory T cells (Tregs) can maintain the autoimmune response (6, 7). One of the root causes of EAE is the decrease in the expression of forkhead box P3 (Foxp3)-expressing auto-inflammatory Tregs and an associated increase in autoimmune Th1 and Th17 cells (8). Moreover, Th17 cells, rather than Th1 cells, are important in autoimmune inflammatory conditions (9). Therefore, the balance of Th17/Tregs may play an important role in the modulation of EAE. IL-10 is an anti-inflammatory cytokine that plays a crucial role in preventing inflammatory and autoimmune pathologies and is involved in the regulation of the Janus kinase/signal transducers and activators of transduction (JAK/STAT) signaling pathway. Genetic deletion of STAT3 in T cells has been shown to abrogate Th17 differentiation, suggesting that STAT3 is a potential therapeutic target for Th17-mediated diseases (10). Tregs can exert their functions by releasing inhibitory cytokines (IL-10 and IL-35) (11). Therefore, the production of inflammatory cytokines (IL-10 and IL-17) and the activation of the JAK/STAT signaling pathway were observed in our study.

With the development of novel treatment methods for autoimmune diseases, transplantation of mesenchymal stem cells (MSCs) has become popular as an effective strategy to counteract the progression of autoimmune disorders. Evidence suggests that MSCs can exert anti-inflammatory and immunomodulatory effects in various tissues, lower the clinical scores, and reduce central nervous system (CNS) leukocyte infiltration in EAE mice (12, 13). Our previous study showed that the immunosuppressive properties of MSCs may be enhanced by interferon gamma (IFN-γ) due to the upregulation of the tryptophan-catabolizing enzyme indoleamine 2,3-dioxygenase (IDO) (14). Therefore, we tried to treat EAE with IFN-γ-primed human umbilical cord MSCs (IFN-γ·hUCMSCs) and investigated their potential therapeutic effects on EAE mice.

Our study demonstrated that transplantation of IFN-γ·hUCMSCs could reduce inflammation in EAE mice via the Foxp3/ROR-γ/STAT3 signaling pathway, highlighting the therapeutic effects of IFN-γ·hUCMSCs in patients with MS.

**Keywords:** IFN-γ·primed human umbilical cord mesenchymal stem cell (IFN-γ·hUCMSCs), multiple sclerosis (MS), experimental autoimmune encephalomyelitis (EAE), indoleamine 2,3-dioxygenase (IDO), Foxp3/ROR-γ/STAT3 signaling pathway

MATERIALS AND METHODS

**Culture of hUCMSCs and IFN-γ·hUCMSCs**

Human umbilical cord specimens were obtained from healthy Chinese young women who received cesarean section at the Second Hospital of Shandong University under sterile conditions. Informed consent was obtained from all participants before the collection of human umbilical cord specimens. This study was approved by the Ethics Committee of the Second Hospital of Shandong University, China.

The hUCMSCs were isolated and cultured, and the phenotype of the hUCMSCs was identified as described in our previous study (14). The umbilical cord was cut into small sections, following two washes with phosphate-buffered saline (PBS). The pieces were digested with collagenase for 1 h and trypsin-EDTA (Gibco, Waltham, MA, USA) for 30 min. The specimens were then filtered, the cells cultured in Dulbecco’s modified Eagle’s medium/nutrient mixture F-12 (HyClone, Logan, UT, USA), and were fixed with 10% fetal bovine serum (Gibco), epidermal growth factor, basic fibroblast growth factor (both from PeproTech, Cranbury, NJ, USA), 1-glutamine (Gibco), and penicillin-streptomycin solution (HyClone) with 5% CO2 at 37°C for 72 h. After 3–5 days, non-adherent cells were removed and the medium was replenished. When the density of the cells reached 80%, they were digested with trypsin-EDTA at room temperature and passaged into new culture dishes. The expressions of the cell surface markers, including CD105, CD90, CD73, CD45, CD34, and HLA-DR (human leukocyte antigen—DR isotype), were evaluated using a LSRFortessa™ flow cytometer (BD Biosciences, Franklin Lakes, NJ, USA). Then, partial human umbilical cord MSCs (hUCMSCs) were pretreated with IFN-γ (20 ng/ml, 48 h). Cell suspensions were prepared at a density of 1 × 10^7 cells/ml.

The whole process was performed in a Good Manufacturing Practice (GMP) laboratory.

**EAE Grouping and Cell Transplantation**

Female C57BL/6J mice (6–8 weeks old; Biotechnology Co., Ltd., Beijing, China) were housed under a 12:12 h light/dark cycle in temperature- and humidity-controlled rooms. Mice were immunized with the myelin oligodendrocyte glycoprotein peptide 35–55 [MOG35-55; GL Biochem (Shanghai) Ltd., Shanghai, China] according to a previously published protocol (15). Priming mice to induce EAE involved complete Freund adjuvant (Sigma, St. Louis, MO, USA) containing 4 mg/ml Mycobacterium tuberculosis (strain H37Ra; Difco, Franklin Lakes, NJ, USA) and 200 μg MOG35-55. On days 0 and 2...
post-immunization, 200 ng of pertussis toxin (Sigma) was administered intraperitoneally. Then, the mice were divided into three groups (n = 8 per group): the EAE group, the hUCMSCs transplantation (EAE+hUCMSCs) group, and the IFN-γ-hUCMSCs transplantation (EAE+IFN-γ-hUCMSCs) group. Fourteen days after immunization, each mouse in the transplantation groups was injected with 100 μl of the cell suspension (1 × 10^6 cells/ml) via the tail vein. The mice in the EAE group were injected with 100 μl of PBS instead. All animal experiments were performed per the Ethical Committee for Animal Experiments of Shandong University, China.

**Body Weight and Clinical Score Assessment**

After immunization, the mice were weighed and evaluated for signs of neurological disability. Clinical disability was scored as follows: 0, no paralysis; 1, loss of tail tone; 2, hindlimb weakness; 3, hindlimb paralysis; 4, hindlimb and forelimb paralysis; and 5, dying or dead (16). The scorers were blinded to the treatment groups.

**Splenocyte Culture and Detection of Inflammatory Cytokines**

Two weeks after cell transplantation, the mice were anesthetized and sacrificed, and the spleens were removed. Splenocytes were cultured as described previously (17).

The spleen tissue was passed through a 100-μm nylon mesh screen to prepare single-cell suspensions, followed by removal of red blood cells with lysis buffer and incubation for 5 min. The suspensions were centrifuged (4°C at 1,200 rpm) and the supernatants collected. Splenocytes were washed twice with RPMI 1640 and adjusted to a density of 1 × 10^6 cells/ml. The cells were incubated at 37°C for 2 h and then stimulated with MOG35-55 (15 μg/ml) for 48 h at 37°C in a 5% CO₂ incubator. After 3 days, the supernatants were harvested and stored at −80°C for cytokine detection using enzyme-linked immunosorbent assay (ELISA).

The contents of IL-10 and IL-17 in the supernatants were assessed using commercially available ELISA kits (Proteintech, Shanghai, China) according to the manufacturer’s instructions. The primer sequences for quantitative real-time PCR (qRT-PCR) are listed in Table 1. Post-transplantation, the supernatants were tested using ELISA. We discovered that transplantation of hUCMSCs and IFN-γ-hUCMSCs significantly alleviated body weight loss and decreased the clinical scores of mice, especially in the IFN-γ-hUCMSCs transplantation group (Figure 1).

**Statistical Analysis**

Data were recorded separately and expressed as the mean ± standard deviation. Data were analyzed using one-way ANOVA and Tukey’s multiple comparisons test. Statistical significance was set at p < 0.05. All data were analyzed using SPSS software (version 23.0).

---

**RESULTS**

**Effects of hUCMSCs and IFN-γ-hUCMSCs Transplantations on the Body Weights and Clinical Scores of EAE Mice**

The body weights and clinical scores of mice were recorded and assessed after immunization. After approximately 2 weeks, EAE mice began to lose weight, and the clinical scores started to increase. We observed that transplantation of hUCMSCs and IFN-γ-hUCMSCs significantly alleviated body weight loss and decreased the clinical scores of mice, especially in the IFN-γ-hUCMSCs transplantation group (Figure 1).

**Inflammatory Cytokines of Splenocyte Culture Supernatants**

To investigate the changes in the inflammatory cytokines after cell transplantations, the contents of IL-10 and IL-17 in splenocyte culture supernatants were tested using ELISA. We discovered that transplantation of hUCMSCs and IFN-γ-hUCMSCs could increase the concentration of IL-10, especially in the IFN-γ-hUCMSCs group. Conversely, IL-17, the pro-inflammatory cytokine, was observed to be remarkably lower in both cell transplantation groups, especially in the IFN-γ-hUCMSCs group (Figure 2). The results showed that transplantation of IFN-γ-hUCMSCs could regulate the

inflammation response more effectively than hUCMSCs in EAE mice.

**mRNA Expression Levels of Foxp3, ROR-γt, and STAT3**

The messenger RNA (mRNA) expression levels of Foxp3, ROR-γt, and STAT3 were determined using qRT-PCR in all transplantation groups (Figure 3). Compared with those in the EAE group, the expressions of STAT3 and ROR-γt in the cell transplantation groups were significantly decreased, but the expression of Foxp3 was upregulated. However, the increase in Foxp3 expression was more significant in the IFN-γ-hUCMSCs transplantation group than that in the hUCMSCs transplantation group.

**DISCUSSION**

MS is a demyelinating disorder induced by activation of the autoimmune system. The treatments for MS mainly include the administration of glucocorticoids in the acute phase, disease
Furthermore, IL-10 may suppress the expression of ROR- without the involvement of any other factors (29). That ROR- receptor ROR-17 is a signature cytokine of Th17 cells. The orphan nuclear differentiation of Th17 cells (28). Recent evidence has shown Foxp3+ Tregs are a special lineage of cells central to the can inhibit Th17 cell differentiation.

In our study, we observed that IFN-γ-hUCMSCs transplantation significantly alleviated body weight loss and decreased the clinical scores of mice. In addition, IFN-γ-hUCMSCs transplantation could regulate the production of inflammatory cytokines (IL-10 and IL-17), thereby showing significantly higher potent treatment efficacy than hUCMSCs transplantation. IL-10, along with its receptors, plays an important role in the pathogenesis of various diseases, including infectious, inflammatory, and autoimmune diseases (25, 26). Studies have shown that bone marrow-derived MSCs can inhibit Th17 cell differentiation via IL-10 secretion (27). IL-17 is a signature cytokine of Th17 cells. The orphan nuclear receptor ROR- is the master regulator that drives the differentiation of Th17 cells (28). Recent evidence has shown that ROR- can potently upregulate IL-17 reporter activity without the involvement of any other factors (29). Furthermore, IL-10 may suppress the expression of ROR-.

CONCLUSION

Our study demonstrated that transplantation of IFN-γ-hUCMSCs could reduce inflammation in EAE mice via the
Foxp3/ROR-γt/STAT3 signaling pathway, which highlights the therapeutic effects of IFN-γ-hUCMSCs in patients with MS. These results suggest that transplantation of IFN-γ-hUCMSCs may be a potential therapy for MS.
