HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
ANALYTIC SCATTERING THEORY FOR JACOBI OPERATORS AND BERNSTEIN-SZEGÖ ASYMPTOTICS OF ORTHOGONAL POLYNOMIALS

D. R. YAFAEV

To the memory of Lyudvig Dmitrievich Faddeev

Abstract. We study semi-infinite Jacobi matrices $H = H_0 + V$ corresponding to trace class perturbations $V$ of the “free” discrete Schrödinger operator $H_0$. Our goal is to construct various spectral quantities of the operator $H$, such as the weight function, eigenfunctions of its continuous spectrum, the wave operators for the pair $H_0, H$, the scattering matrix, the spectral shift function, etc. This allows us to find the asymptotic behavior of the orthonormal polynomials $P_n(z)$ associated to the Jacobi matrix $H$ as $n \to \infty$. In particular, we consider the case of $z$ inside the spectrum $[-1, 1]$ of $H_0$ when this asymptotics has an oscillating character of the Bernstein-Szegö type and the case of $z$ at the end points $\pm 1$.

1. Introduction

1.1. The theory of the Schrödinger operator $D^2 + b(x), D = -id/dx$, with a short-range potential $b(x)$ is to a large extent due to L. D. Faddeev. We note, in particular, his classical papers [11, 12] on the direct and inverse quantum scattering problems (both in the one- and multi-dimensional cases) and [10] on the trace formulas for the operator $D^2 + b(x)$. Later, the paper [10] was significantly generalized by him jointly with V. S. Buslaev in [4]. Some of these results were exposed in the book [13] by L. D. Faddeev and L. A. Takhtajan.

As is well known, the theories of Jacobi operators given by three-diagonal matrices and of differential operators $Da(x)D + b(x)$ are to a large extent similar. This is true for Jacobi operators acting in the space $\ell^2(\mathbb{Z})$ and differential operators acting in the space $L^2(\mathbb{R})$ as well as for the corresponding operators acting in the spaces $\ell^2(\mathbb{Z}_+)$ and $L^2(\mathbb{R}_+)$, respectively. We refer to the book [27] where this analogy is described in a sufficiently detailed way. Both classes of the operators are very important in physical applications. Moreover, Jacobi operators in the space $\ell^2(\mathbb{Z}_+)$ are intimately related (see, e.g., the classical book [1]) to the theory of orthogonal polynomials. Necessary
information on orthogonal polynomials can be found in the other classical book [26]; the theory of Jacobi operators is carefully presented in the books [1, 2].

Our goal is to develop the spectral and scattering theory for Jacobi operators in the space $\ell^2(\mathbb{Z}^+)$. This leads to new results for orthogonal polynomials.

1.2. Jacobi operators are defined in the space $\ell^2(\mathbb{Z}^+)$ by matrices

$$H = \begin{pmatrix}
    b_0 & a_0 & 0 & 0 & 0 & \cdots \\
    a_0 & b_1 & a_1 & 0 & 0 & \cdots \\
    0 & a_1 & b_2 & a_2 & 0 & \cdots \\
    0 & 0 & a_2 & b_3 & a_3 & \cdots \\
    \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
\end{pmatrix}.$$ (1.1)

The entries $a_n$ are arbitrary positive numbers, and $b_n$ are arbitrary real numbers. We denote by $e_n$, $n \in \mathbb{Z}^+$, the canonical basis in $\ell^2(\mathbb{Z}^+)$, that is, all components of the vector $e_n$ are zeros, except the $n$-th component which equals 1. If the sequences $\{a_n\}$ and $\{b_n\}$ are bounded, then the Jacobi operator $H$ is bounded in $\ell^2(\mathbb{Z}^+)$. Let us denote by $dE(\lambda)$ the spectral family of the self-adjoint operator $H$ and define the corresponding spectral measure $d\rho(\lambda) = d(E(\lambda)e_0, e_0)$.

Given matrix (1.1), one constructs polynomials $P_n(z)$ by the recurrent relation

$$a_{n-1}P_{n-1}(z) + b_nP_n(z) + a_nP_{n+1}(z) = zP_n(z), \quad n \in \mathbb{Z}^+,$$ (1.2)

and the boundary conditions $P_{-1}(z) = 0$, $P_0(z) = 1$. Then $P_n(z)$ is a polynomial of degree $n$, that is,

$$P_n(z) = k_n(z^n + r_nz^{n-1} + \cdots).$$ (1.3)

Comparing the coefficients at $z^{n+1}$ and $z^n$ in the left- and right-hand sides of (1.2), we see that $k_n = (a_0a_1\cdots a_{n-1})^{-1} > 0$ and

$$a_n = \frac{k_n}{k_{n+1}}, \quad b_n = r_n - r_{n+1}.$$ (1.4)

Obviously, $P(z) = \{P_n(z)\}_{n=0}^{\infty}$ satisfies the equation $HP(z) = zP(z)$, that is, it is an "eigenvector" of the operator $H$.

Putting together (1.1) and (1.2), we find that

$$e_n = P_n(H)e_0$$ (1.5)

for all $n \in \mathbb{Z}^+$. It follows that

$$d(E(\lambda)e_n, e_m) = P_n(\lambda)P_m(\lambda)d\rho(\lambda),$$

whence

$$\int_{-\infty}^{\infty} P_n(\lambda)P_m(\lambda)d\rho(\lambda) = \delta_{n,m};$$ (1.6)
as usual, $\delta_{n,n} = 1$ and $\delta_{n,m} = 0$ for $n \neq m$. Thus, the polynomials $P_n(\lambda)$ are orthogonal and normalized in the space $L^2(\mathbb{R};d\rho)$. Formula (1.5) also shows that the set of all vectors $H^ne_0$, $n \in \mathbb{Z}_+$, is dense in the space $\ell^2(\mathbb{Z}_+)$, and hence the spectrum of the Jacobi operator $H$ is simple with the generating vector $e_0$.

Alternatively, \{\begin{array}{c}
P_0(\lambda), P_1(\lambda), \ldots, P_n(\lambda), \ldots \end{array}\} can be obtained by the Gram-Schmidt orthogonalization of the monomials \{1, \lambda, \ldots, \lambda^n, \ldots\} in the space $L^2(\mathbb{R}_+;d\rho)$; one also has to additionally require that $k_n > 0$ in (1.3). This fact is known as the Favard theorem. In contrast to the continuous case (see the paper [15] where an integral equation was used), the inverse problem of reconstructing the Jacobi operator $H$ given its spectral measure $d\rho(\lambda)$ admits a quite explicit solution. Indeed, let a measure $d\rho(\lambda)$ have a bounded and infinite support, and let $P_n(z)$ be the corresponding polynomials satisfying (1.3) and (1.6). Then the coefficients of the operator $H$ can be recovered by formulas (1.4).

1.3. In the particular case $a_n = 1/2$ and $b_n = 0$, the operator (1.1) is denoted $H_0$. It plays the role of the “free” differential operator $D^2$ in the space $L^2(\mathbb{R}_+)$ with the boundary condition $u(0) = 0$. The operator $H_0$ can be diagonalized explicitly.

In this paper, we suppose that the perturbation $V = H - H_0$ satisfies a “short-range” assumption

$$\sum_{n=0}^{\infty} (|a_n - 1/2| + |b_n|) < \infty.$$  \hspace{1cm} (1.7)

Then $V$ belongs to the trace class $\mathcal{S}_1$, and its trace norm is equivalent to the sum (1.7). Under assumption (1.7) the spectrum $\sigma(H)$ of the operator $H$ is absolutely continuous on the interval $(-1,1)$, but the operator $H$ may have discrete spectrum $\sigma_d(H)$ (possibly, infinite) in $\mathbb{R} \setminus [-1,1]$; moreover, the points $+1$ or $-1$ may be its eigenvalues.

We construct various spectral quantities of the operator $H$, such as the weight function $w(\lambda)$ defined by the equation $d\rho(\lambda) = w(\lambda)d\lambda$ for $\lambda \in (-1,1)$, eigenfunctions of its continuous spectrum, the perturbation determinant $\Delta(z)$ and the wave operators $W_{\pm}(H,H_0)$ for the pair $H_0, H$, the scattering matrix $S(\lambda)$, the spectral shift function $\xi(\lambda)$, etc. Under assumption (1.7) the functions $w(\lambda)$, $S(\lambda)$ and $\xi(\lambda)$ are continuous in $\lambda \in (-1,1)$. Moreover, $w(\lambda) \neq 0$ and, as shown in [20], the so-called Szegö condition

$$\int_{-1}^{1} \ln w(\lambda)(1 - \lambda^2)^{-1/2}d\lambda > -\infty$$  \hspace{1cm} (1.8)

is satisfied.

Spectral results on Jacobi operators lead to the corresponding assertions for the polynomials $P_n(z)$ defined by (1.2). For example, we show (see Theorem 2.5) that, for $\lambda \in (-1,1)$,

$$P_n(\lambda) = \sqrt{\frac{2}{\pi}} w(\lambda)^{-1/2}(1 - \lambda^2)^{-1/4} \sin((n + 1) \arccos \lambda + \pi \xi(\lambda)) + o(1)$$  \hspace{1cm} (1.9)
as \( n \to \infty \). This asymptotic relation is the classical result of S. Bernstein [3] (see also formula (12.1.8) in the G. Szeg"o book [26]). It is required in [3, 26] that \( \text{supp} \rho \subset [-1,1] \) and Lipschitz-Dini conditions are imposed on the weight function \( w(\lambda) \). Under assumption (1.7) formula (1.9) is probably new. In particular, we do no assume that \( \text{supp} \rho \subset [-1,1] \). Note that the spectral shift function \( \xi(\lambda) \) in formula (1.9) is usually replaced in the theory of orthogonal polynomials by the so-called Szego function.

As shows the example of Pollaczek polynomials (see formula (7.14), below), assumption (1.7) cannot be significantly relaxed. For Pollaczek polynomials, \( a_n - 1/2 \) and \( b_n \) have order \( n^{-1} \) as \( n \to \infty \), and the phase in formula (1.9) is essentially changed (see Section 5 in the Appendix to [26]). This resembles the modification of the phase function for the Schr"odinger operator with the Coulomb potential (see, e.g., formula (36,23) in the book [22]).

As shown in the paper [4] by V. S. Buslaev and L. D. Faddeev (see Section 4.6 in [30], for a detailed presentation), the expansion as \( |z| \to \infty \) of the perturbation determinant \( \Delta(z) \) for a pair \( H_0, H \) of Schr"odinger operators contains both integer and half-integer powers of \( z^{-1} \). This leads to two series of trace identities: of integer and of half-integer orders. The first of them is stated in terms of integer powers of eigenvalues and moments of the spectral shift function. The second series is stated in terms of half-integer powers of eigenvalues and moments of the modulus of the perturbation determinant. For Jacobi operators \( H_0, H \), the expansion of the perturbation determinant \( \Delta(z) \) as \( |z| \to \infty \) contains integer powers of \( z^{-1} \) only. So there are no identities of half-integer orders. On the other hand, there is a version of trace identities of integer order (known as Case sum rules) stated in terms of the weight function, that is, of the modulus of the perturbation determinant. We note that the Case sum rules involve Chebyshev polynomials of the operators \( H_0 \) and \( H \) while the identities in spirit of [4] yield expressions for the traces \( \text{Tr}(H^n - H_0^n) \).

This paper contains relatively few new results. However, we hope that a consistent analogy between Jacobi and differential operators might shed a new light on some aspects of the theory of orthogonal polynomials. A similar point of view was adopted in the paper [20] devoted to Hilbert-Schmidt perturbations \( V \) of the operator \( H_0 \).

Note that, in [20], necessary and sufficient conditions in terms of spectral data of \( H \) were found for \( V \) to be in the Hilbert-Schmidt class. The problem of characterization of spectral data was also solved in [24] for perturbations \( V \) in the class (it is known now as the Ryckman class) relatively close to the trace class \( \mathcal{S}_1 \). It looks tempting to obtain exhaustive results of such type for \( V \in \mathcal{S}_1 \).

1.4. The paper is organized as follows. In Section 2, we consider equation (1.2) and, in addition to its polynomial solutions \( P_n(z) \), we introduce so-called Jost solutions \( f_n(z) \) of this equation. The Jost function \( \Omega(z) \) basically coincides with \( f_{-1}(z) \). The solutions \( f_n(z) \) exponentially decay as \( n \to \infty \) for \( z \notin \sigma(H_0) = [-1,1] \) and oscillate for \( z = \lambda \pm i0 \) where \( \lambda \in (-1,1) \). Then a link between \( f_n(\lambda \pm i0) \) and \( P_n(\lambda) \) leads to asymptotic formulas for polynomials \( P_n(\lambda) \). Thus, we obtain formula (1.9) (with the
argument of $\Omega(\lambda \pm i0)$ playing the role of $\xi(\lambda)$); see Theorem 2.5. Polynomial solutions $P_n(z)$ and their asymptotics as $n \to \infty$ for $z \not\in [-1,1]$ are studied in Section 3. Our proofs of the existence of $f_n(z)$ and uniform bounds on $P_n(z)$ rely on discrete “Volterra integral” equations that are studied in the Appendix.

Section 4 is devoted to an investigation of the Jost solutions $f_n(z)$ and the polynomials $P_n(z)$ as $z \to \pm 1$. This corresponds to the low energy scattering for the Schrödinger equation. In particular, we exhibit here examples of Jacobi operators with eigenvalues at the points 1 or $-1$.

In Section 5, we construct the perturbation determinant $\Delta(z)$ and the spectral shift function for the pair $H_0, H$ and derive formulas for the traces $\text{Tr}(H^n - H_0^n)$. We also show in Theorem 5.6 that the Jost function $\Omega(z)$ differs from $\Delta(z)$ by a numerical factor only. Scattering theory for the pair $H_0, H$ is developed in Section 6.

A link of the Szegö function with the perturbation determinant (or the Jost function) is established in Section 7. We here also show (again on the example of Pollaczek polynomials) that the weight function $w(\lambda)$ may tend to zero exponentially if assumption (1.7) is slightly relaxed. Therefore the Szegö condition (1.8) is sharp for trace class perturbations. In Section 8, the results of the preceding sections are illustrated on the example of the Jacobi polynomials when $a_n - 1/2$ and $b_n$ have order $n^{-2}$ as $n \to \infty$.

Some parts of this paper have non-trivial intersections with Section 2 of the paper [20] where, however, specific features of the Jacobi operators were extensively used. The analogy with the continuous case exploited in the present paper allows us to obtain some results for free.

The modern approach based on a Riemann-Hilbert problem for matrix valued functions of [14] combined with the steepest descent method of [7] is out of the scope of the present paper.

2. Jost solutions of the Jacobi equations and Bernstein-Szegö asymptotics

2.1. In the canonical basis $e_n$, $n \in \mathbb{Z}_+$, the Jacobi operator $H$ is defined by the formula

$$He_n = a_{n-1}e_{n-1} + b_ne_n + a_ne_{n+1}, \quad n \in \mathbb{Z}_+,$$

(2.1)

where we accept that $e_{-1} = 0$. Relations (1.1) and (2.1) are of course equivalent. The sequences $a_n > 0$ and $b_n \doteq \bar{b}_n$ where $n = 0, 1, \ldots$ are assumed to be bounded, so that $H$ is a bounded self-adjoint operator in the space $\ell^2(\mathbb{Z}_+)$. Consider now the equation $Hu = zu$, that is

$$a_{n-1}u_{n-1} + b_nu_n + a_nu_{n+1} = zu_n, \quad n \in \mathbb{Z}_+,$$

(2.2)

for a sequence $u = \{u_n\}_{n=-1}^{\infty}$. The number $a_{-1} \neq 0$ can be chosen at our convenience; for definiteness, we put $a_{-1} = 1/2$. Obviously, the values of $u_{k-1}$ and $u_k$ for some $k \in \mathbb{Z}_+$ determine the whole sequence $u_n$ satisfying equation (2.2).
Let $f = \{f_n\}_{n=-1}^{\infty}$ and $g = \{g_n\}_{n=-1}^{\infty}$ be two solutions of equation (2.2). A direct calculation shows that their Wronskian
\[
\{f, g\} := a_n(f_{n+1}g_n - f_n g_{n+1})
\]
does not depend on $n = -1, 0, 1, \ldots$. In particular, for $n = -1$ and $n = 0$, we have
\[
\{f, g\} = 2^{-1}(f_{-1}g_0 - f_0 g_{-1}) \quad \text{and} \quad \{f, g\} = a_0(f_0 g_1 - f_1 g_0).
\]
Calculating the Wronskian (2.3) for $n \to \infty$, we see that equation (2.2) may have at most one (up to a multiplicative constant) solution $u_n$ such that $u_n \to 0$ as $n \to \infty$.

In the case $a_n = 1/2$, $b_n = 0$, the operator (2.1) is known as the free discrete Schrödinger operator; it will be denoted $H_0$. The spectrum of the operator $H_0$ is simple, absolutely continuous and coincides with the interval $[-1, 1]$. The corresponding spectral measure $d\rho_0(\lambda) = d(E_0(\lambda)\epsilon_0, \epsilon_0)$ is given by the formula
\[
d\rho_0(\lambda) = 2\pi^{-1}\sqrt{1 - \lambda^2}d\lambda, \quad \lambda \in (-1, 1).
\]

Below we fix the branch of the analytic function $\sqrt{z^2 - 1}$ of $z \in \mathbb{C} \setminus [-1, 1] =: \Pi$ by the condition $\sqrt{z^2 - 1} > 0$ for $z > 1$. Obviously, this function is continuous on the closure $\text{clos} \Pi$ of $\Pi$, it equals $\pm i\sqrt{1 - \lambda^2}$ for $z = \lambda \pm i0$, $\lambda \in (-1, 1)$, and $\sqrt{z^2 - 1} < 0$ for $z < -1$. Put
\[
\zeta(z) = z - \sqrt{z^2 - 1} = (z + \sqrt{z^2 - 1})^{-1};
\]
then $|\zeta(z)| < 1$ for $z \in \Pi$. Since
\[
2z = \zeta(z) + \zeta(z)^{-1},
\]
the sequence $\{\zeta(z)^n\}_{n=-1}^{\infty}$ satisfies the "free" equation (2.2): $\zeta(z)^{n-1} + \zeta(z)^{n+1} = 2z\zeta(z)^n$. For $\lambda \in [-1, 1]$, it is common to set $\lambda = \cos \theta$ where $\theta \in [0, \pi]$. Then
\[
\zeta(\lambda \pm i0) = e^{\mp i\theta}.
\]

It is well known (see, e.g., [31] for a detailed proof) that the matrix elements of the resolvent $R_0(z) = (H_0 - zI)^{-1}$ (here and below $I$ is the identity operator) of the operator $H_0$ are given by the formula
\[
(R_0(z)e_n, e_m) = \frac{\zeta(z)^{n+m+2} - \zeta(z)^{|n-m|}}{\sqrt{z^2 - 1}}
\]
for $z \in \Pi$ and all $n, m \in \mathbb{Z}_+$. In particular, $(R_0(z)e_0, e_0) = -2\zeta(z)$. The polynomials $P_n^{(0)}(z)$ defined by the recurrent equation (1.2) where $a_n = 1/2$, $b_n = 0$ and obeying the conditions $P_{-1}^{(0)}(z) = 0$, $P_0^{(0)}(z) = 1$ are normalized Chebyshev polynomials of the second kind. They satisfy the equation
\[
P_n^{(0)}(z) = \frac{1}{2\sqrt{z^2 - 1}}(\zeta(z)^{-n-1} - \zeta(z)^{n+1})
\]
and, in particular,
\[
P_n^{(0)}(\lambda) = \frac{\sin((n + 1)\theta)}{\sqrt{1 - \lambda^2}}, \quad \lambda = \cos \theta \in (-1, 1).
\]
Evidently, the “perturbation” $V = H - H_0$ is given by the equality

$$Ve_n = (a_{n-1} - 1/2)e_{n-1} + b_ne_n + (a_n - 1/2)e_{n+1}. \tag{2.10}$$

If $a_n \to 1/2$ and $b_n \to 0$ as $n \to \infty$, then the operator $V$ is compact. In this case the essential spectrum of the operator $H$ coincides with the interval $[-1, 1]$, and its discrete spectrum $\sigma_d(H)$ consists of simple eigenvalues accumulating, possibly, to the points 1 and $-1$ only.

Under assumption (1.7) the equation (2.2) has the so called Jost solution $f(z) = \{f_n(z)\}_{n=-1}^\infty$ distinguished by its asymptotics as $n \to \infty$. Our proof of this fact is similar to the continuous case, but we give it for the completeness of our presentation in Appendix A.1. It is based on the discrete Volterra integral equation

$$f_n(z) = \zeta(z)^n - \frac{1}{\sqrt{z^2 - 1}} \sum_{m=n+1}^\infty (\zeta(z)^{n-m} - \zeta(z)^{m-n})(Vf(z))_m \tag{2.11}$$

where $z \in \Pi$ and $V$ is defined by formula (2.10). A somewhat different proof can be found in [20] (see also the book [27]). Put

$$\rho_n = \sum_{m=n}^\infty (|a_m - 1/2| + |b_m|). \tag{2.12}$$

Then $\rho_n \to 0$ as $n \to \infty$.

**Theorem 2.1.** Let assumption (1.7) be satisfied, and let $z \in \text{clos} \Pi$, $z \neq \pm 1$. Then equation (2.2) has a solution satisfying the condition

$$f_n(z) = \zeta(z)^n(1 + O(\rho_n)) \tag{2.13}$$

as $n \to \infty$. Every function $f_n(z)$, $n = -1, 0, 1, \ldots$, depends analytically on $z \in \Pi$, and it is continuous in $z$ up to the cut along $[-1, 1]$ except, possibly, the points $\pm 1$.

Since $|\zeta(z)| < 1$, it follows from (2.13) that $f_n(z) \to 0$ exponentially as $n \to \infty$ for $z \in \Pi$. In particular, equation (2.2) has only one solution satisfying (2.13). Note that for the operator $H_0$, the error term in (2.13) disappears and the Jost function is $f_n(z) = \zeta(z)^n$.

Recall that the polynomials $P_n(z)$ are defined by equation (2.2) and the conditions $P_{-1}(z) = 0$, $P_0(z) = 1$. Put $P(z) = \{P_n(z)\}_{n=-1}^\infty$, $f(z) = \{f_n(z)\}_{n=-1}^\infty$,

$$\omega(z) := \{P(z), f(z)\} = -2^{-1}f_{-1}(z), \tag{2.14}$$

where the first formula (2.4) has been used. In particular, for the operator $H_0$ we have $\omega_0(z) = -(2\zeta(z))^{-1}$. By analogy with the continuous case, we define the Jost function

$$\Omega(z) := \omega(z)/\omega_0(z) = -2\zeta(z)\omega(z). \tag{2.15}$$

The following result is a direct consequence of Theorem 2.1.
Corollary 2.2. Under assumption (1.7) the Jost function $\Omega(z)$ depends analytically on $z \in \Pi$, and it is continuous in $z$ up to the cut along $[-1,1]$ except, possibly, the points $\pm 1$. A point $z \in \Pi$ is an eigenvalue of the operator $H$ if and only if $\omega(z) = 0$.

Theorem 2.1 can be supplemented by the following assertion.

Theorem 2.3. Under the assumptions of Theorem 2.1 put $a_{n}^{(N)} = a_{n}, b_{n}^{(N)} = b_{n}$ for $n \leq N$ and $a_{n}^{(N)} = 1/2, b_{n}^{(N)} = 0$ for $n > N$. Let $f_{n}^{(N)}(z)$ be the Jost solution of equation (2.2) with the coefficients $a_{n}^{(N)}, b_{n}^{(N)}$. Then for each $n \geq -1$, we have

$$\lim_{N \to \infty} f_{n}^{(N)}(z) = f_{n}(z), \quad z \in \text{clos} \Pi, \quad z \neq \pm 1. \quad (2.16)$$

2.3. For $\lambda \in (-1,1)$, equation (2.2) where $z = \lambda$ has two solutions $f(\lambda \pm i0) = \{f_{n}(\lambda \pm i0)\}_{n=-1}^{\infty}$; of course $f_{n}(\lambda - i0) = f_{n}(\lambda + i0)$. It follows from Theorem 2.1 and formula (2.7) that asymptotics of $f_{n}(\lambda \pm i0)$ as $n \to \infty$ is oscillating:

$$f_{n}(\lambda \pm i0) = e^{\mp i\theta_{n}}(1 + O(\rho_{n})), \quad \theta = \arccos \lambda \in (0, \pi). \quad (2.17)$$

Calculating their Wronskian (2.3) for $n \to \infty$, we find that

$$\{f(\lambda + i0), f(\lambda - i0)\} = i \sin \theta \neq 0, \quad \sin \theta = \sqrt{1 - \lambda^2}, \quad (2.18)$$

so that these solutions are linearly independent. Thus,

$$P_{n}(\lambda) = c(\lambda)f_{n}(\lambda + i0) + c(\lambda)f_{n}(\lambda - i0) \quad (2.19)$$

for some constant $c(\lambda)$. Taking the Wronskians of this equation with $f(\lambda + i0)$ and using (2.14), (2.18), we find that

$$\sin \theta c(\lambda) = i\omega(\lambda + i0).$$

Of course $\omega(\lambda - i0) = \omega(\lambda + i0)$. Thus (2.19) leads to an intermediary result.

Lemma 2.4. Under assumption (1.7) the representation

$$P_{n}(\lambda) = \frac{\omega(\lambda - i0)f_{n}(\lambda + i0) - \omega(\lambda + i0)f_{n}(\lambda - i0)}{i\sqrt{1 - \lambda^2}}, \quad \lambda \in (-1,1), \quad n = 0, 1, 2, \ldots, \quad (2.20)$$

holds true.

In particular, representation (2.20) implies that

$$\omega(\lambda \pm i0) \neq 0, \quad \lambda \in (-1,1). \quad (2.21)$$

Indeed, otherwise we would have $P_{n}(\lambda) = 0$ for some $\lambda \in (-1,1)$ and all $n \in \mathbb{Z}_{+}$. However, $P_{0}(\lambda) = 1$ for all $\lambda$.

Let us set

$$\varphi(\theta) = |\Omega(\cos \theta + i0)|, \quad \Omega(\cos \theta + i0) = \varphi(\theta)e^{in\theta}, \quad \theta \in (0, \pi). \quad (2.22)$$

In the theory of the Schrödinger operator, the functions $\varphi(\theta)$ and $\eta(\theta)$ are known as the limit amplitude and the limit phase, respectively; the function $\eta(\theta)$ is also known.
as the scattering phase or the phase shift. Definition (2.22) fixes \( \eta(\theta) \) only up to a term \( 2\pi k \) where \( k \in \mathbb{Z} \).

It follows from (2.7) and (2.15) that

\[
2\omega(\lambda \pm i0) = -\Omega(\lambda \pm i0)\zeta(\lambda \pm i0)^{-1} = -\kappa(\theta)e^{\pm i(\eta(\theta) + \theta)}.
\]

Therefore, combined together relations (2.17) and (2.20) yield the Bernstein-Szegö asymptotics of the polynomials \( P_n(\lambda) \).

**Theorem 2.5.** Under assumption (1.7) for \( \lambda \in (-1, 1) \) the polynomials \( P_n(\lambda) \) have asymptotics

\[
P_n(\lambda) = \kappa(\theta)(\sin \theta)^{-1} \sin((n + 1)\theta + \eta(\theta)) + O(\rho_n), \quad \theta = \arccos \lambda,
\]

as \( n \to \infty \). Relation (2.23) is uniform in \( \lambda \) on compact subintervals of \((-1, 1)\).

**2.4.** Let us construct the resolvent \( R(z) = (H - zI)^{-1} \) of the operator \( H \). Recall that \( \omega(z) \) is the Wronskian (2.14).

**Lemma 2.6.** For all \( n, m \in \mathbb{Z}_+ \), we have

\[
(R(z)e_n, e_m) = \omega(z)^{-1}P_n(z)f_m(z), \quad z \in \Pi,
\]

if \( n \leq m \) and \( (R(z)e_n, e_m) = (R(z)e_m, e_n) \).

**Proof.** We will show that the operator \( R(z) \) defined by (2.24) is the resolvent of \( H \). We have

\[
\omega(z)(R(z)u)_n = f_n(z)A_n(z) + P_n(z)B_n(z)
\]

where

\[
A_n(z) = \sum_{m=0}^{n} P_m(z)u_m, \quad B_n(z) = \sum_{m=n+1}^{\infty} f_m(z)u_m,
\]

at least for all sequences \( u = \{u_n\} \) with a finite number of non-zero components \( u_n \). In this case \( R(z)u \in \ell^2(\mathbb{Z}_+) \) because \( f_n(z) \in \ell^2(\mathbb{Z}_+) \) for all \( z \in \Pi \).

Our goal is to check that \((H - z)R(z)u = u\). It follows from definition (1.1) of the Jacobi operator \( H \) and formula (2.25) that

\[
\omega((H - z)Ru)_n = a_{n-1}(f_{n-1}A_{n-1} + P_{n-1}B_{n-1})
\]

\[
+ (b_n - z)(f_nA_n + P_nB_n) + a_n(f_{n+1}A_{n+1} + P_{n+1}B_{n+1}).
\]

According to (2.26) we have

\[
f_{n-1}A_{n-1} + P_{n-1}B_{n-1} = f_{n-1}(A_n - P_nu_n) + P_{n-1}(B_n + f_nu_n)
\]

and

\[
f_{n+1}A_{n+1} + P_{n+1}B_{n+1} = f_{n+1}A_n + P_{n+1}B_n.
\]
Let us substitute these expressions into the right-hand side of (2.27) and observe that the coefficients at $A_n$ and $B_n$ equal zero by virtue of equation (2.2) for \{f_n\} and \{P_n\}, respectively. It follows that

$$((H - z)Ru)_n = \omega^{-1}a_{n-1}(-P_nf_{n-1} + f_nP_{n-1})u_n = u_n$$

whence $R(z) = (H - z)^{-1}$; in particular, the operator $R(z)$ defined by (2.24) is bounded in $\ell^2(\mathbb{Z}_+)$. \qed

In view of Theorem 2.1, $f_n(z)$ and $\omega(z)$ are continuous functions of $z \in \mathbb{C} \setminus [-1, 1]$ up to the cut along $[-1, 1]$ with possible exception of the points $z = \pm 1$. Therefore using (2.21), we obtain the following result.

**Theorem 2.7.** Let assumption (1.7) hold. Then, for all $n, m \in \mathbb{Z}_+$, the functions $(R(z)e_n, e_m)$ are continuous as $z \in \Pi$ approaches the interval $(-1, 1)$ from above or below, and the spectrum of the operator $H$ is absolutely continuous on $(-1, 1)$.

We emphasize that the points 1 and $-1$ may be eigenvalues of $H$; see Example 4.15 below.

Let us now calculate the spectral family $dE(\lambda)$ of the operator $H$. We proceed from the identity

$$2\pi id(E(\lambda)e_n, e_m) = (R(\lambda + i0)e_n, e_m) - (R(\lambda - i0)e_n, e_m). \quad (2.28)$$

It follows from formula (2.24) that

$$(R(\lambda \pm i0)e_n, e_m) = \omega(\lambda \pm i0)^{-1}P_n(\lambda)f_m(\lambda \pm i0), \quad n \leq m.$$  

Substituting this expression into (2.28), we find that

$$2\pi id(E(\lambda)e_n, e_m) = P_n(\lambda)\frac{\omega(\lambda - i0)f_m(\lambda + i0) - \omega(\lambda + i0)f_m(\lambda - i0)}{\omega(\lambda + i0)^2}.$$  

Let us combine this representation with formula (2.20) for $P_n(\lambda)$. Since $2|\omega(\lambda+i0)| = |\Omega(\lambda+i0)|$, we obtain the following result.

**Theorem 2.8.** Let assumption (1.7) hold. Then, for all $n, m \in \mathbb{Z}_+$ and $\lambda \in (-1, 1)$, we have the representation

$$\frac{d(E(\lambda)e_n, e_m)}{d\lambda} = 2\pi^{-1}\sqrt{1 - \lambda^2}\left|\Omega(\lambda + i0)\right|^{-2}P_n(\lambda)P_m(\lambda).$$  

**Corollary 2.9.** For $\lambda \in (-1, 1)$, the spectral measure of the operator $H$ equals

$$d\rho(\lambda) := d(E(\lambda)e_0, e_0) = w(\lambda)d\lambda, \quad (2.29)$$

where the weight function

$$w(\lambda) = 2\pi^{-1}\sqrt{1 - \lambda^2}\left|\Omega(\lambda + i0)\right|^{-2}. \quad (2.30)$$

In particular, for the operator $H_0$, we have

$$w_0(\lambda) = 2\pi^{-1}\sqrt{1 - \lambda^2}. \quad (2.31)$$
In view of (2.22), (2.30) the amplitude in (2.23) can be written as
\[
\kappa(\theta)(\sin \theta)^{-1} = 2^{1/2} \pi^{-1/2} (1 - \lambda^2)^{-1/4} w(\lambda)^{-1/2}
\] (2.32)
which is more common in the orthogonal polynomials literature.

Note that Theorem 2.1 does not give any information on the behavior of the Jost function \( \Omega(z) \) as \( z \to \pm 1 \). However relation (2.30) implies that
\[
\int_{-1}^{1} \sqrt{1 - \lambda^2} |\Omega(\lambda + i0)|^{-2} d\lambda = \frac{\pi}{2} \int_{-1}^{1} w(\lambda) d\lambda \leq \frac{\pi}{2},
\] (2.33)
and hence \( \Omega(\lambda + i0) \) cannot vanish too rapidly as \( \lambda \to 1 - 0 \) and \( \lambda \to -1 + 0 \) (even if 1 or \(-1\) are eigenvalues of \( H \)). For example, the behavior \( \Omega(\lambda + i0) \sim c_{\pm}(\lambda \mp 1) \) where \( c_{\pm} \neq 0 \) is excluded.

3. Regular solutions of the Jacobi equations

3.1. The regular solution \( P(z) = \{P_n(z)\} \) of the Jacobi equation (1.2) is determined by the boundary conditions \( P_{-1}(z) = 0, P_0(z) = 1 \). Then \( P_n(z) \) is a polynomial of degree \( n \) and relation (1.6) is satisfied. By analogy with the continuous case (see, e.g., part 1 of Section 4.1 in [30]), we here obtain bounds on \( P_n(z) \) for large \( n \). As usual, the variable \( \zeta(z) \) is defined by (2.5).

**Theorem 3.1.** If assumption (1.7) is satisfied, then
\[
|P_n(z)| \leq C |\zeta(z)|^{-n}
\] (3.1)
with some positive constant \( C \) not depending on \( n \) and on \( z \) in compact subsets of \( \mathbb{C} \setminus \{-1, 1\} \).

Theorem 3.1 will be proven in Appendix A.2. The proof relies on the equation (cf. equation (2.11))
\[
P_n(z) = P_n^{(0)}(z) + \frac{1}{\sqrt{z^2 - 1}} \sum_{n=0}^{n-1} (\zeta(z)^{n-m} - \zeta(z)^{m-n})(VP(z))_m, \quad n \geq 1,
\] (3.2)
where \( z \in \Pi, P_n^{(0)}(z) \) (normalized Chebyshev polynomials of the second kind) are given by equation (2.8) and \( V \) is defined by formula (2.10).

Recall now formula (2.24) for the resolvent \( R(z) \) of the operator \( H \). Putting together estimates (2.13) and (3.1), we obtain the following result.

**Theorem 3.2.** Let assumption (1.7) be satisfied. For all \( n, m \in \mathbb{Z}_+ \), the functions \( (R(z)e_n, e_m) \) are continuous in \( z \) up to the cut along \([-1, 1]\) except, possibly, the points \( \pm 1 \). Moreover,
\[
|(R(z)e_n, e_m)| \leq C |\omega(z)|^{-1} |\zeta(z)|^{n-m}
\] with some positive constant \( C \) that does not depend on \( n, m \) and on \( z \) in compact subsets of \( \text{clos } \Pi \) and away from the points \( \pm 1 \).
We need also a representation of the Jost function $\Omega(z)$ in terms of the orthogonal polynomials $P_n(z)$. It plays the role of the representation (see, e.g., formula (1.38) in Chapter 4 of [30]) of the Jost function via the regular solution of the Schrödinger equation in the continuous case.

**Proposition 3.3.** Let assumption (1.7) be satisfied, and let the Jost function $\Omega(z)$ be defined by (2.14). Then

$$
\Omega(z) = 1 - 2 \sum_{n=0}^{\infty} \zeta(z)^{n+1}(VP(z))_n
$$

for all $z \in \text{clos} \Pi$ except, possibly, the points $\pm 1$.

**Proof.** Suppose first that $z = \lambda + i0$ where $\lambda \in (-1, 1)$. Substituting expressions (2.9) and (2.20) into equation (3.2) we see that

$$
\omega(\lambda - i0)f_n(\lambda + i0) - \omega(\lambda + i0)f_n(\lambda - i0) = 2^{-1}(e^{i(n+1)\theta} - e^{-i(n+1)\theta})
$$

$$
+ \sum_{m=0}^{n-1} (e^{-i(n-m)\theta} - e^{-i(n-m)\theta})(VP(\lambda + i0))_m.
$$

Let us consider the asymptotics of both sides of this equation as $n \to \infty$ and use relation (2.17). Then comparing coefficients at $e^{in\theta}$, we get (3.3) for $z = \lambda + i0$. Both sides of (3.3) are analytic in $z \in \Pi$ and continuous up to the cut along $[-1, 1]$ according to Theorems 2.1 and 3.1. Therefore relation (3.3) extends to all $z$. \qed

**3.2.** Let us find asymptotics of the polynomials $P_n(z)$ for $z \not\in [-1, 1]$. We follow here closely the scheme exposed in Section 4.1 (see, in particular, Lemma 1.11) of [30].

We start by introducing solutions $g_n(z)$ of equation (2.2) exponentially growing as $n \to \infty$. Perhaps this construction is of interest in its own sake. For $z \in \Pi$, fix $n_0 = n_0(z)$ such that $f_n(z) \neq 0$ for $n \geq n_0 - 1$. Note that, for $\text{Im} z \neq 0$, one can set $n_0 = 0$ because the equality $f_{n_0 - 1}(z) = 0$ implies that the Jacobi operator $H^{(n_0)}$ with the matrix elements $a_{n_0}^{(n_0)} = a_{n_0+n_0}$, $b_{n_0}^{(n_0)} = b_{n+n_0}$ has the eigenvalue $z$. Put

$$
g_n(z) = f_n(z)\Theta_n(z) \quad \text{where} \quad \Theta_n(z) = \sum_{m=n_0}^{n} (a_{m-1}f_{m-1}(z)f_m(z))^{-1}. \quad (3.4)
$$

An elementary calculation shows that this sequence satisfies equation (2.2). It is also easy to find the asymptotics of $g_n(z)$ as $n \to \infty$:

$$
\zeta^n g_n(z) = 2\zeta^{2n} \sum_{m=n_0}^{n} \zeta^{-2m+1}(1 + o(1)) = 2\zeta^{2n+1}\frac{\zeta^{-2n+2} - 1}{\zeta^{-2} - 1} (1 + o(1))
$$

$$
= 2\frac{1 - \zeta^{-2n+2}}{\zeta^{-1} - \zeta} (1 + o(1)) = \frac{1 + o(1)}{\sqrt{z^2 - 1}}
$$
where \( \zeta = \zeta(z) \). This yields the following result.

**Lemma 3.4.** Let \( z \in \Pi \). Under assumption (1.7) the sequence \( g_n(z) \) defined by (3.4) satisfies equation (2.2) and

\[
\lim_{n \to \infty} \zeta(z)^n g_n(z) = \frac{1}{\sqrt{z^2 - 1}}.
\]

The Wronskian (2.3) of \( f(z) = \{ f_n(z) \}, g(z) = \{ g_n(z) \} \) equals

\[
\{ f(z), g(z) \} = a_n f_n(z) f_{n+1}(z) (\Theta_{n+1}(z) - \Theta_n(z)) = 1,
\]

and hence solutions \( f(z) \) and \( g(z) \) are linearly independent. It follows that

\[
P_n(z) = d_+(z)f_n(z) + d_-(z)g_n(z) \tag{3.5}
\]

where

\[
\{ P(z), f(z) \} = d_-(z)\{ g(z), f(z) \} = -d_-(z)
\]

and

\[
\{ P(z), g(z) \} = d_+(z)\{ f(z), g(z) \} = d_+(z).
\]

According to (2.14), (2.15) we have

\[
d_-(z) = (2 \zeta(z))^{-1} \Omega(z). \tag{3.6}
\]

Obviously, \( d_+(z) \neq 0 \) if \( d_-(z) = 0 \). Therefore Lemma 3.4 implies the following result.

**Theorem 3.5.** Under assumption (1.7) for all \( z \in \Pi \), we have the relation

\[
\lim_{n \to \infty} \zeta(z)^n P_n(z) = \frac{\Omega(z)}{1 - \zeta(z)^2} \tag{3.7}
\]

with convergence uniform on compact subsets of \( \Pi \). Moreover, if \( \Omega(z) = 0 \), then

\[
\lim_{n \to \infty} \zeta(z)^{-n} P_n(z) = \{ P(z), g(z) \} \neq 0. \tag{3.8}
\]

The existence of the limit in (3.7) is the classical result of the Szegő theory. It is stated as Theorem 12.1.2 in the book [26] where the assumptions are imposed on the measure \( d\rho(\lambda) \); in particular, it is assumed that \( \text{supp} \rho \subset [-1, 1] \). Under assumption (1.7) asymptotic relation (3.7) was established in Theorem 2.20 of [20]; our proof is rather different from that in [20]. Relation (3.8) is perhaps new.

4. **Edge points of the spectrum**

4.1. A study of the Jost function \( \Omega(z) \) as \( z \to 1 \) and \( z \to -1 \) requires an additional assumption on the coefficients \( a_n, b_n \). This is quite similar to the Schrödinger operator in the space \( L^2(\mathbb{R}_+) \) that has a threshold at the point \( z = 0 \). The presentation here follows very closely Section 4.3 of [30] where the continuous case was considered; so some technical details will be omitted.
Theorem 4.1. Suppose that
\[ \sum_{n=0}^{\infty} n(|a_n - 1/2| + |b_n|) < \infty. \] (4.1)
Then all functions \( f_n(z) \) and, in particular, the Jost function \( \Omega(z) \) are continuous in \( z \) up to the cut along \([ -1, 1 ]\). Moreover, \( f_n(\pm 1) \) satisfies equation (2.2) for \( z = \pm 1 \), that is
\[ a_{n-1}f_{n-1}(\pm 1) + b_nf_n(\pm 1) + a_nf_{n+1}(\pm 1) = \mp f_n(\pm 1), \quad n \in \mathbb{Z}_+, \] (4.2)
and \( f_n(\pm 1) = (\pm 1)^n + o(1) \) as \( n \to \infty \).

Theorem 3.1 can be supplemented by the following result.

Theorem 4.2. If assumption (4.1) is satisfied, then
\[ |P_n(z)| \leq C(n + 1)|\zeta(z)|^{-n} \] (4.3)
with some positive constant \( C \) not depending on \( n \) and on \( z \) in compact subsets of \( \mathbb{C} \).

The proofs of Theorem 4.1 and 4.2 will be discussed in Appendix A.3. We emphasize that assumption (4.1) cannot be relaxed; see Remark 4.13 below.

Passing in (2.11) to the limit \( z \to \pm 1 \) and taking into account the relation
\[ \zeta(z)^k = (\pm 1)^k(1 \mp k\sqrt{z^2 - 1}) + O(|z^2 - 1|), \quad z \to \pm 1, \] (4.4)
we obtain an equation for the sequences \( f_n(\pm 1) \):
\[ f_n(\pm 1) = (\pm 1)^n + 2 \sum_{m=n+1}^{\infty} (\pm 1)^{n-m+1}(n-m)(Vf(\pm 1))_m. \]
Similarly, since \( P_n^{(0)}(\pm 1) = (n + 1)(\pm 1)^n \), equation (3.2) yields
\[ P_n(\pm 1) = (n + 1)(\pm 1)^n - 2 \sum_{m=0}^{n-1} (\pm 1)^{n-m+1}(n-m)(VP(\pm 1))_m. \] (4.5)

Estimate (4.3) allows us to pass to the limit \( z \to \pm 1 \) in (3.3) which leads to the following result.

Lemma 4.3. Under assumption (4.1), the representation
\[ \Omega(\pm 1) = 1 - 2 \sum_{n=0}^{\infty} (\pm 1)^{n+1}(VP(\pm 1))_n \] (4.6)
holds.

Similarly to Lemma 3.4, we can introduce a solution \( g_n(\pm 1) \) of the equation (4.2) linearly independent with \( f_n(\pm 1) \).
**Lemma 4.4.** Let assumption (4.1) hold. Define the sequence \( g_n(\pm 1) \) by formula (3.4). Then \( g_n(\pm 1) \) satisfies equation (4.2), \( g_n(\pm 1) = 2(\pm 1)^{n+1}n(1 + o(1)) \) as \( n \to \infty \) and \( \{f(\pm 1), g(\pm 1)\} = 1 \).

Since neither of solutions \( f_n(\pm 1), g_n(\pm 1) \) nor their linear combinations tend to zero as \( n \to \infty \), we obtain

**Theorem 4.5.** Under assumption (4.1) equations (4.2) do not have solutions tending to zero as \( n \to \infty \). In particular, the operator \( H \) cannot have eigenvalues 1 and \(-1\).

To find the asymptotics of the polynomials \( P_n(z) \) at critical points \( z = \pm 1 \), we use equalities (3.5) and (3.6) where \( z = \pm 1 \). The next result is a direct consequence of Lemma 4.4.

**Theorem 4.6.** Let assumption (4.1), and let \( \Omega(\pm 1) \neq 0 \). Then

\[
P_n(\pm 1) = \Omega(\pm 1)(\pm 1)^nn(1 + o(1)) \tag{4.7}
\]

Of course, if \( \Omega(\pm 1) \neq 0 \), then according to (2.24) the resolvent kernel \( (R(z)e_n, e_m) \) is continuous as \( z \to \pm 1 \).

4.2. Our next goal is to find the asymptotic behavior as \( z \to \pm 1 \) of \( \Omega(z) \) and hence of \( (R(z)e_n, e_m) \) in the exceptional case \( \Omega(\pm 1) = 0 \). Let us use the same terminology as for Schrödinger operators.

**Definition 4.7.** Let assumption (4.1) hold. If \( \Omega(\pm 1) = 0 \), we say that the operator \( H \) has a resonance at \( z = \pm 1 \).

Clearly, the condition \( \Omega(\pm 1) = 0 \) is equivalent to the linear dependence of the solutions \( P_n(\pm 1) \) and \( f_n(\pm 1) \) of equation (4.2). In this case the sequence \( P_n(\pm 1) \) is bounded as \( n \to \infty \). The next result follows from equations (4.5) and (4.6).

**Lemma 4.8.** Suppose that \( \Omega(\pm 1) = 0 \) and put

\[
\gamma_\pm = 1 + 2 \sum_{m=0}^{\infty} (\pm 1)^{m-1}m(VP(\pm 1))_m. \tag{4.8}
\]

Then there exists

\[
\lim_{n \to \infty} (\pm 1)^nP_n(\pm 1) = \gamma_\pm \neq 0. \tag{4.9}
\]

In particular, \( P_n(\pm 1) = (\pm 1)^n\gamma_\pm f_n(\pm 1) \).

Now we are in a position to find the asymptotic behavior of the Jost function \( \Omega(z) \) as \( z \to \pm 1 \) in the case \( \Omega(\pm 1) = 0 \). Let us proceed from representation (3.3). According to (4.4), for each \( n \), we have

\[
\zeta(z)^{n+1}(VP(z))_n = ((\pm 1)^{n+1} - (\pm 1)^n(n + 1)\sqrt{z^2 - 1})(VP(\pm 1))_n + O(z^2 - 1).
\]
Substituting this expression into (3.3) and taking into account equation (4.6), we see that

\[ \Omega(z) = \Omega(\pm 1) + 2 \sum_{n=0}^{\infty} (\pm 1)^n (n+1) (VP(\pm 1))_n \sqrt{z^2 - 1} + o(\sqrt{|z^2 - 1|}). \]

If \( \Omega(\pm 1) = 0 \), then the coefficient at \( \sqrt{z^2 - 1} \) here equals \( \pm \gamma_{\pm} \). Let us state the result obtained.

**Theorem 4.9.** Under assumption (4.1) suppose that \( \Omega(\pm 1) = 0 \) and define the number \( \gamma_{\pm} \) by (4.8) or, equivalently, by (4.9). Then

\[ \Omega(z) = \pm \gamma_{\pm} \sqrt{z^2 - 1} + o(\sqrt{|z^2 - 1|}) \]

as \( z \to \pm 1 \).

Using formula (2.30), we obtain the following consequence for the weight function.

**Corollary 4.10.** Under the assumptions of Theorem 4.9, we have

\[ w(\lambda) = 2\pi^{-1} \gamma_{\pm}^{-2} (1 - \lambda^2)^{-1/2} (1 + o(1)), \quad \lambda \in (-1, 1), \]

as \( \lambda \to \pm 1 \).

In view of Lemmas 2.6 and 4.8, Theorem 4.9 implies also the following result.

**Corollary 4.11.** Under the assumptions of Theorem 4.9 for all \( n, m \in \mathbb{Z}_+ \), the representation

\[ (R(z)e_n, e_m) = -2(\pm 1)^{\min(n,m)} f_n(\pm 1) f_m(\pm 1) + o(1) \]

\[ \sqrt{z^2 - 1} \]

as \( z \to \pm 1 \) is satisfied.

**Remark 4.12.** Combined together, Theorems 4.1 and 4.9 ensure that under assumption (4.1) the discrete spectrum of the operator \( H \) is finite.

**Remark 4.13.** Under assumption (4.1) the asymptotics of the orthogonal polynomials \( P_n(\pm 1) \) is given by formulas (4.7) and (4.9). An example of the Jacobi polynomials shows that the asymptotics of \( P_n(\pm 1) \) is significantly changed (see formula (8.18), below) if the condition (4.1) is even slightly relaxed. In particular, estimate (4.3) is violated in this case.

**Remark 4.14.** The problem of characterization of spectral data corresponding to assumption (4.1) was considered in [17].

4.3. The condition (4.1) of Theorem 4.5 guaranteeing, in particular, the absence of eigenvalues \( \pm 1 \) is optimal. Indeed, there exist Jacobi operators satisfying condition (1.7) but not (4.1) with an eigenvalue at the points +1 or −1. In the example below, we suppose that \( a_n = 1/2 \). Set

\[ \psi_n^{(\pm)} = (\pm 1)^n (n+1)^{-l} \]

(4.10)
for all $n \in \mathbb{Z}_+$ and $\psi_n^{(\pm)} = 0$. Then $\psi_n^{(\pm)} = \{\psi_n^{(\pm)}\} \in \ell^2(\mathbb{Z}_+)$ if $l > 1/2$. Let us consider equation (2.2) where $u_n = \psi_n^{(\pm)}$ and $z = \pm 1$ as an equation for $b_n^{(\pm)}$:

$$b_n^{(\pm)} = \pm 1 - (2\psi_n^{(\pm)})^{-1}(\psi_{n-1}^{(\pm)} + \psi_{n+1}^{(\pm)}).$$

(4.11)

It follows from (4.10) that

$$b_n^{(\pm)} = \mp 2^{-1}l(l + 3)n^{-2} + O(n^{-3})$$

as $n \to \infty$. In particular, condition (1.7) holds. Moreover, up to a finite rank operator, the perturbation $V^{(\pm)} = H^{(\pm)} - H_0$ of the operator $H_0$ is negative for the upper sign and positive for the lower sign. Thus, we have

**Example 4.15.** Let $a_n = 1/2$ and $b_n^{(\pm)}$ be given by formulas (4.10) where $l > 1/2$ and (4.11). Then condition (1.7) is satisfied. The Jacobi operator $H^{(\pm)}$ has the eigenvalue $\pm 1$ with the eigenvector $\psi_n^{(\pm)}$ defined by (4.10). The spectrum of $H^{(\pm)}$ is finite above the point 1, and spectrum of $H^{(-)}$ is finite below the point $-1$.

Note that the operators $H^{(\pm)}$ have infinite number of eigenvalues. For instance, this fact follows from a general result of [6], Theorem 3, stating that the spectrum of a Jacobi operator is purely absolutely continuous on $[-1, 1]$ if it has only a finite number of eigenvalues outside $[-1, 1]$. In our case $H^{(\pm)}$ has the eigenvalue $\pm 1$.

Example 4.15 exhibits an asymptotic behavior of orthogonal polynomials $P_n(z)$ intermediary between exponential (for $z \not\in [-1, 1]$) and oscillating (for $z \in (-1, 1)$) regimes. Indeed, if $a_n = 1/2$ and $b_n^{(\pm)}$ are defined by (4.10) and (4.11), then $P_n^{(\pm)}(\pm 1) = \psi_n^{(\pm)}$ are given by (4.10). So, this sequence behaves as some power of $n$ (negative or positive) as $n \to \infty$.

**4.4.** A similar result is true for the Schrödinger operator $H = -d^2/dx^2 + b(x)$ with the boundary condition $u(0) = 0$ in the space $L^2(\mathbb{R}_+)$. Let $\psi \in \mathcal{C}^{\infty}(\mathbb{R}_+)$, $\psi(x) > 0$ for all $x > 0$, $\psi(x) = x$ in a neighborhood of the point $x = 0$ and

$$\psi(x) = x^{-l} \quad \text{where} \quad l > 1/2$$

(4.12)

for sufficiently large $x$. Then $\psi \in L^2(\mathbb{R}_+)$. Put

$$b(x) = \psi''(x)\psi(x)^{-1}$$

(4.13)

so that $b(x) = l(l+1)x^{-2}$ if $x$ is large enough. This yields

**Example 4.16.** Let $b(x)$ be given by formulas (4.12) and (4.13). Then the operator $H$ has the eigenvalue 0 with the eigenfunction $\psi(x)$ defined by (4.12), and its negative spectrum is finite.

The decay of $b(x)$ as $|x|^{-2}$ at infinity is critical. Actually, it is known (see part 1 in Section 4.3 of [30]) that $H$ cannot have the zero eigenvalue provided

$$\int_0^\infty (1 + x)|b(x)|dx < \infty.$$
5. THE PERTURBATION DETERMINANT AND THE SPECTRAL SHIFT FUNCTION.

Trace identities

5.1. Let $H_0$ and $H$ be arbitrary self-adjoint operators with a trace class difference $V = H - H_0$. Then the perturbation determinant

$$\Delta(z) = \text{Det} \left( I + VR_0(z) \right)$$

(5.1)

for the pair $H_0, H$ is well defined and is an analytic function of $z \in \mathbb{C} \setminus \sigma(H_0)$. Obviously, $\Delta(\bar{z}) = \Delta(z)$ and

$$\Delta(z) \to 1 \quad \text{as} \quad \text{dist}\{z, \sigma(H_0)\} \to \infty.$$  \hspace{1cm} (5.2)

Note also the general formula

$$\text{Tr} \left( R(z) - R_0(z) \right) = -\frac{\Delta'(z)}{\Delta(z)}.$$  \hspace{1cm} (5.3)

In view of our applications to Jacobi operators, below we suppose that the operators $H_0$ and $H$ are bounded.

The Kreĭn spectral shift function $\xi(\lambda)$ is defined in terms of the perturbation determinant (5.1). According to (5.2) we can fix the branch of the function $\ln \Delta(z)$ for $\text{Im} \, z \neq 0$ by the condition

$$\arg \Delta(z) \to 0 \quad \text{as} \quad \text{dist}\{z, \sigma(H_0)\} \to \infty.$$  \hspace{1cm} (5.4)

Then

$$\xi(\lambda) := \pi^{-1} \lim_{\varepsilon \to +0} \arg \Delta(\lambda + i\varepsilon).$$  \hspace{1cm} (5.5)

This limit exists for a.e. $\lambda \in \mathbb{R}$,

$$\int_{-\infty}^{\infty} |\xi(\lambda)| d\lambda \leq \|V\|_1$$  \hspace{1cm} (5.6)

and the representation

$$\ln \Delta(z) = \int_{-\infty}^{\infty} \frac{\xi(\lambda)(\lambda - z)^{-1}}{\Delta(z)} d\lambda, \quad \text{Im} \, z \neq 0,$$  \hspace{1cm} (5.7)

holds. The function $\xi(\lambda)$ is constant on intervals not containing points of $\sigma(H_0) \cup \sigma(H)$. In particular, $\xi(\lambda) = 0$ for $\lambda < \inf \left( \sigma(H_0) \cup \sigma(H) \right)$ and $\lambda > \sup \left( \sigma(H_0) \cup \sigma(H) \right)$. If $\lambda_1$ is an isolated eigenvalue of finite multiplicity $k_0$ of the operator $H_0$ and multiplicity $k$ of the operator $H$, then

$$\xi(\lambda_1 + 0) - \xi(\lambda_1 - 0) = k_0 - k.$$  \hspace{1cm} (5.8)

We refer to the books [16, 25, 29] for a detailed presentation of these notions.

5.2. Let us come back to Jacobi operators. Under the assumption (1.7), the perturbation $V$ belongs to the trace class $\mathcal{S}_1$ so that all results mentioned in the previous subsection are true.
Let us find a link of the perturbation determinant \( \Delta(z) \) with the Jost function (2.15). We follow here closely the scheme of the paper [4] where the operator \(-D^2 + b(x)\) was considered; for its detailed presentation, see Section 4.1 of [30]. Note that there exists also a different to proofs of such assertions relying on the Fredholm expansion of determinants; this approach was developed in [19].

Let us find an expression of the left-hand side of (5.3) in terms of the Jost function \( \Omega(z) \). The first assertion is true without any assumptions on \( a_n \) and \( b_n \). Recall that \( \{f_n(z)\}_{n=-1}^{\infty} \) is the Jost solution of equations (2.2) and \( \omega(z) \) is defined by (2.14).

**Lemma 5.1.** For all \( z \in \Pi \) and all \( N \geq 0 \), we have the identity

\[
\sum_{n=0}^{N} f_n(z)P_n(z) = -\omega'(z) + a_N(P_N(z)f_{N+1}'(z) - P_{N+1}(z)f_N'(z)). \tag{5.9}
\]

**Proof.** Let us differentiate (in \( z \)) equation (2.2) for \( f_n(z) \) and then multiply it by \( P_n(z) \):

\[
a_{n-1}f_{n-1}'(z)P_n(z) + a_nf_{n+1}'(z)P_n(z) = (z - b_n)f'_n(z)P_n(z) + f_n(z)P_n(z). \tag{5.10}
\]

Multiplying equation (1.2) for \( P_n(z) \) by \( f'_n(z) \), we see that

\[
a_{n-1}P_{n-1}(z)f_n'(z) + a_nP_{n+1}(z)f'_n(z) = (z - b_n)P_n(z)f'_n(z). \tag{5.11}
\]

Then we subtract (5.11) from (5.10):

\[
f_n(z)P_n(z) = (a_{n-1}f_{n-1}'(z)P_n(z) - a_nf_n'(z)P_{n+1}(z))
+ (a_nf_{n+1}'(z)P_n(z) - a_{n-1}f_n'(z)P_{n-1}(z)). \tag{5.12}
\]

Let us calculate the sums of the right-hand sides over \( n = 0, 1, \ldots, N \):

\[
\sum_{n=0}^{N} (a_{n-1}f_{n-1}'(z)P_n(z) - a_nf_n'(z)P_{n+1}(z)) = 2^{-1}f_{-1}'(z)P_0(z) - a_Nf_N'(z)P_{N+1}(z)
\]

and

\[
\sum_{n=0}^{N} (a_nf_{n+1}'(z)P_n(z) - a_{n-1}f_n'(z)P_{n-1}(z)) = a_Nf_{N+1}'(z)P_N(z) - 2^{-1}f_0'(z)P_{-1}(z).
\]

Since \( P_{-1}(z) = 0 \), \( P_0(z) = 1 \) and \( f_{-1}(z) = -2\omega(z) \), taking the sum of equations (5.12), we obtain the identity (5.9).

Let us calculate the asymptotics of the right-hand side of (5.9) as \( n \to \infty \) supposing first that the perturbation \( V \) has finite support, that is, \( a_n = 1/2 \) and \( b_n = 0 \) for sufficiently large \( n \). In view of (2.6), the equations (2.2) are satisfied in this case for all \( z \in \Pi \) and \( n \) large enough if \( u_n(z) \) is an arbitrary linear combination of the functions \( \zeta(z)^n \) and \( \zeta(z)^{-n} \). In particular, we have

\[
f_n(z) = \zeta(z)^n \quad \text{and} \quad P_n(z) = \gamma_+(z)\zeta(z)^n + \gamma_-(z)\zeta(z)^{-n} \tag{5.13}
\]

for some numbers \( \gamma_\pm(z) \). Recall that \( |\zeta(z)| < 1 \) for \( z \in \Pi \).
Lemma 5.2. For all \( z \in \Pi, z \not\in \sigma_d(H) \) and \( n \to \infty \), we have the relation
\[
\omega(z)^{-1}(P_n(z)f'_{n+1}(z) - P_{n+1}(z)f'_n(z)) = -\frac{2n}{\sqrt{z^2 - 1}} + \frac{\zeta(z)}{z^2 - 1} + O(\zeta(z)^2n).
\] (5.14)

Proof. It follows from formulas (5.13) that the Wronskian (2.14) calculated for large \( n \) is given by the equation
\[
2\omega = (\gamma_+\zeta^n + \gamma_-\zeta^{-n})\zeta^{n+1} - (\gamma_+\zeta^{n+1} + \gamma_-\zeta^{-n-1})\zeta^n = \gamma_-(\zeta - \zeta^{-1}).
\] (5.15)
Formulas (5.13) also imply that
\[
P_n f'_{n+1} - P_{n+1} f'_n = (\gamma_+\zeta^n + \gamma_-\zeta^{-n})(\zeta^{n+1})' - (\gamma_+\zeta^{n+1} + \gamma_-\zeta^{-n-1})(\zeta^n)' = -\frac{1}{\sqrt{z^2 - 1}}(\gamma_-(n+1)\zeta - n\zeta^{-1} + (n+1)\zeta^{2n+1})
\] (5.16)
where we used that
\[
\zeta(z)' = -\frac{\zeta(z)}{\sqrt{z^2 - 1}}.
\]
Dividing now (5.16) by (5.15), we arrive at (5.14). \(\square\)

Using expression (2.24) for \((R(z)e_n, e_n)\) and putting together Lemmas 5.1 and 5.2, we get the following result.

Theorem 5.3. Suppose that \( a_n = 1/2 \) and \( b_n = 0 \) for sufficiently large \( n \). Then for all \( z \in \Pi, z \not\in \sigma_d(H) \) and \( N \to \infty \), we have the relation
\[
\sum_{n=0}^{N}(R(z)e_n, e_n) = -\omega'(z)\omega(z)^{-1} - \frac{N}{\sqrt{z^2 - 1}} + \frac{\zeta(z)}{2(z^2 - 1)} + O(\zeta(z)^2N).
\] (5.17)

Of course the same formula is true for the operator \( H_0 \) when \( \omega_0(z) = -2^{-1}\zeta(z)^{-1} \). Comparing formulas (5.17) for \( H \) and \( H_0 \), we find that
\[
\sum_{n=0}^{N}((R(z)e_n, e_n) - (R_0(z)e_n, e_n)) = -\omega'(z)\omega(z)^{-1} + \omega_0'(z)\omega_0(z)^{-1} + O(\zeta(z)^2N).
\]
Passing here to the limit \( N \to \infty \), we see that
\[
\text{Tr} \left( R(z) - R_0(z) \right) = -\frac{\Omega'(z)}{\Omega(z)}, \quad z \in \Pi,
\] (5.18)
where the function \( \Omega(z) \) is defined by (2.15).

Theorem 2.3 allows us to extend this result to arbitrary operators satisfying condition (1.7). Indeed, set \( a_n^{(N)} = a_n, b_n^{(N)} = b_n \) for \( n \leq N \) and \( a_n^{(N)} = 1/2, b_n^{(N)} = 0 \) for \( n > N \). Let \( H^{(N)} \) be the Jacobi operator with the matrix elements \( a_n^{(N)}, b_n^{(N)} \), and let \( \Omega^{(N)}(z) = -2\zeta(z)\{P^{(N)}(z), f^{(N)}(z)\} \). Write formula (5.18) for the pair \( H_0, H^{(N)} \) and...
pass to the limit $N \to \infty$. Since $V^{(N)} := H^{(N)} - H_0 \to V$ in the trace norm, we see that
\[ \text{Tr} \left( R^{(N)}(z) - R_0(z) \right) \to \text{Tr} \left( R(z) - R_0(z) \right) \]
as $N \to \infty$. According to Theorem 2.3 we also have $\Omega^{(N)}(z) \to \Omega(z)$ and hence $d\Omega^{(N)}(z)/dz \to d\Omega(z)/dz$ as $N \to \infty$. This leads to the desired result.

**Theorem 5.4.** The relation (5.18) holds true under assumption (1.7).

### 5.3. Putting together relations (5.3) and (5.18), we see that
\[ \Delta(z) = A \Omega(z), \quad z \in \Pi, \]for some constant $A \in \mathbb{C}$. Our goal is to check that
\[ A = \prod_{k=0}^{\infty} (2a_k). \]Note that under assumption (1.7) the infinite product here converges and $A > 0$.

Let us compare the asymptotics of $\Delta(z)$ and $\Omega(z)$ as $|z| \to \infty$. The first of them is given by (5.2). So we only have to consider the Jost function $\Omega(z)$.

**Lemma 5.5.** Suppose that $a_n = 1/2$ and $b_n = 0$ for all sufficiently large $n$. Then for all $n = -1, 0, 1, \ldots$ and $|z| \to \infty$, we have the asymptotic relation
\[ f_n(z) = \left( \prod_{k=n}^{\infty} (2a_k) \right)^{-1} \zeta(z)^n (1 + O(\zeta(z))). \]In particular,
\[ \Omega(z) = A^{-1} + O(\zeta(z)). \]

**Proof.** Since $f_n(z) = \zeta^n$ for $n$ large enough, relations (5.21) are certainly satisfied for such $n$. Suppose that, for some $n_0$, relations (5.21) are true for all $n \geq n_0$. According to equation (2.2) we have
\[ a_{n_0-1}f_{n_0-1} = (2^{-1}(\zeta + \zeta^{-1}) - b_{n_0}) f_{n_0} - a_{n_0}f_{n_0+1}. \]
By our assumption on $f_{n_0}$ and $f_{n_0+1}$, this implies
\[ a_{n_0-1}f_{n_0-1} = 2^{-1} \zeta^{-1} \left( \prod_{k=n_0}^{\infty} (2a_k) \right)^{-1} \zeta^{n_0}(1 + O(\zeta)) + O(\zeta^{n_0}) \]
which yields (5.21) for $f_{n_0-1}$. In view of (2.14), (2.15), relation (5.22) is a consequence of (5.21) for $n = -1$. □

Thus relations (5.19) and (5.20) are verified for perturbations of finite support. It remains to extend them to arbitrary perturbations satisfying assumption (1.7). Let us use the arguments and the notation $H^{(N)} = H_0 + V^{(N)}$, $\Omega^{(N)}(z)$ already used by the
proof of Theorem 5.4. Let \( \Delta^{(N)}(z) \) be the perturbation determinant for the pair \( H_0, H^{(N)} \). For all \( N \), we have the relation
\[
\Delta^{(N)}(z) = A^{(N)} \Omega^{(N)}(z) \quad \text{where} \quad A^{(N)} = \prod_{k=0}^{N-1} (2a_k).
\]
Let us pass here to the limit \( N \to \infty \). Since \( V^{(N)} \to V \) in the trace norm, \( \Delta^{(N)}(z) \to \Delta(z) \) as \( N \to \infty \). We also see that \( \Omega^{(N)}(z) \to \Omega(z) \) by Theorem 2.3 and \( A^{(N)} \to A \) under assumption (1.7). This yields the desired result.

**Theorem 5.6.** Under assumption (1.7) the equality (5.19) is true with constant (5.20).

Since \( \Delta(z) \) satisfies (5.2), this gives us the asymptotics of the Jost function at infinity.

**Corollary 5.7.** Under assumption (1.7) we have
\[
\lim_{|z| \to \infty} \Omega(z) = A^{-1}.
\]
Thus, we can fix the branch of the function \( \arg \Omega(z) \) for \( \text{Im} \, z \neq 0 \) by the condition
\[
\lim_{|z| \to \infty} \arg \Omega(z) = 0.
\]
Then in view of normalization (5.4), we have
\[
\arg \Delta(z) = \arg \Omega(z), \quad \text{Im} \, z \neq 0.
\]

5.4. Next, we discuss the spectral shift function \( \xi(\lambda) \) for a pair of Jacobi operators \( H_0, H \) satisfying assumption (1.7). According to Theorem 2.1 and formula (5.19), the perturbation determinant \( \Delta(z) \) is a continuous function of \( z \in \text{clos} \, \Pi \) except, possibly, the points \( z = \pm 1 \). Moreover, according to (2.21), we have \( \Omega(\lambda \pm i0) \neq 0 \). Therefore \( \xi(\lambda) \) is also a continuous function of \( \lambda \in (-1, 1) \).

A link between \( \xi(\lambda) \) and the scattering phase \( \eta(\theta) \) follows from definitions (2.22) and (5.5).

**Theorem 5.8.** Under assumption (1.7), the relation
\[
\xi(\lambda) = \pi^{-1} \eta(\arccos \lambda)
\]
holds for all \( \lambda \in (-1, \lambda) \).

Substituting (5.23) into (2.23) and taking into account (2.32), we can reformulate Theorem 2.5 in terms of the weight function \( w(\lambda) \) and the spectral shift function \( \xi(\lambda) \). This yields asymptotic relation (1.9); note that the remainder \( o(1) \) in the right-hand side can be replaced by \( O(\rho_n) \).

We emphasize that \( \eta(\theta) \) is a continuous function of \( \theta \in (0, \pi) \), but Theorem 2.1 yields no information about its behavior as \( \theta \to 0 \) and \( \theta \to \pi \). Comparing relations (5.6) and (5.23), we however see that
\[
\int_0^\pi |\eta(\theta)| \sin \theta d\theta \leq \pi \|V\|_1.
\]
5.5. To find expressions of $\text{Tr}(H^n - H_0^n)$ in terms of the spectral shift function, we only have to compare asymptotic expansions as $|z| \to \infty$ of both sides of the representation (5.7). It follows from relation (5.3) that

$$\ln \Delta(z) = -\sum_{n=1}^{\infty} n^{-1} \text{Tr}(H^n - H_0^n) z^{-n}.$$  

Since

$$\int_{-\infty}^{\infty} \xi(\lambda)(\lambda - z)^{-1} d\lambda = -\sum_{n=1}^{\infty} \int_{-\infty}^{\infty} \xi(\lambda) \lambda^{n-1} d\lambda z^{-n},$$

equating the coefficients at $z^{-n}$, we see that

$$\text{Tr}(H^n - H_0^n) = n \int_{-\infty}^{\infty} \xi(\lambda) \lambda^{n-1} d\lambda.$$  \hspace{1cm} (5.24)

On the discrete spectrum, the spectral shift function can be explicitly calculated. Indeed, let $\lambda_1^{(+)} > \lambda_2^{(+)} > \cdots > 1$ (and $\lambda_1^{(-)} < \lambda_2^{(-)} < \cdots < -1$) be eigenvalues of $H$ lying above the point 1 (respectively, below the point $-1$). It follows from formula (5.8) that $\xi(\lambda) = n$ for $\lambda \in (\lambda_{n+1}^{(+)}, \lambda_n^{(+)})$ and $\xi(\lambda) = -n$ for $\lambda \in (\lambda_n^{(-)}, \lambda_{n+1}^{(-)})$.

Using formula (5.8), we find that

$$n \int_{1}^{\infty} \xi(\lambda) \lambda^{n-1} d\lambda = \sum_{k=1}^{\infty} k((\lambda_k^{(+)})^n - (\lambda_{k+1}^{(+)})^n)$$

and, similarly, for the integral over $(-\infty, -1)$. The series here is convergent by virtue of estimate (5.6). Putting together this relation with (5.24), we obtain the following result.

**Theorem 5.9.** Let assumption (1.7) be satisfied. Then

$$\text{Tr}(H^n - H_0^n) = n \int_{1}^{\infty} \xi(\lambda) \lambda^{n-1} d\lambda + \sum_{k=1}^{\infty} k((\lambda_k^{(+)})^n - (\lambda_{k+1}^{(+)})^n) + \sum_{k=1}^{\infty} k((\lambda_k^{(-)})^n - (\lambda_{k+1}^{(-)})^n).$$  \hspace{1cm} (5.25)

In view of (5.23), the integral on the right can be expressed in terms of the phase function:

$$\int_{1}^{\infty} \xi(\lambda) \lambda^{n-1} d\lambda = \frac{1}{\pi} \int_{0}^{\pi} \eta(\theta) \cos^{n-1} \theta \sin \theta d\theta.$$

In a very general framework, formulas of type (5.25) were studied in the book [27], Chapter 6.

5.6. The trace formula of zero order (the Levinson theorem) requires a special discussion. Now we assume a stronger condition (4.1) on the coefficients of the operator $H$. Then according to Theorem 4.1, the corresponding perturbation determinant $\Delta(z)$ is continuous as $z \to \pm 1$. One has to distinguish the cases $\Delta(1) = 0$ and $\Delta(-1) = 0$. 

when the operator $H$ has threshold resonances at the points $\lambda = 1$ or $\lambda = -1$. Note also (see Remark 4.12) that under assumption (4.1) the operator $H$ has only a finite number $N$ of discrete eigenvalues.

**Theorem 5.10.** Let assumption (4.1) be satisfied. Then the limits $\xi(1 - 0)$ and $\xi(-1 + 0)$ exist and

$$\xi(1 - 0) - \xi(-1 + 0) = N + \kappa$$

(5.26)

where $\kappa = 0$ if $\Delta(\pm 1) \neq 0$ for both signs, $\kappa = 1/2$ if $\Delta(\pm 1) = 0$ for one of the signs and $\kappa = 1$ if $\Delta(\pm 1) = 0$ for both signs.

**Proof.** Let us consider a contour which consists of a part $C_{r-} - C_{r+} = [1 - r_--i0, 1 - r_+ - i0] \cup [1 - r_+ - i0, 1 - r_- - i0] \cup \{|z - 1| = r_+\} \cup \{|z + 1| = r_+\}$ encircling the cut along $[-1, 1]$ and of the circle $|z| = R$. We suppose that $r_-$ and $r_+$ are sufficiently small, $R$ is sufficiently large, and we go in the clockwise over $C_{r-} - C_{r+}$ and in the counter-clockwise direction over $|z| = R$. Since $\Delta(z)$ has simple zeros at the eigenvalues of $H$, the argument principle implies that

$$\text{var}^{C_{r-} - C_{r+}} \arg \Delta(z) + \text{var}^{|z|=R} \arg \Delta(z) = 2\pi N.$$  

(5.27)

According to (5.4) we have $\text{var}^{|z|=R} \arg \Delta(z) \to 0$ as $R \to \infty$. It follows from (5.5) that

$$\text{var}^{C_{r-} - C_{r+}} \arg \Delta(z) = 2\pi(\xi(1 - r_+ - \xi(1 + r_-)) \text{var}^{|z-1|=r_+} \arg \Delta(z) + \text{var}^{|z+1|=r_-} \arg \Delta(z).$$

(5.28)

Let us now pass here to the limit $r_-, r_+ \to 0$. If $\Delta(\pm 1) \neq 0$, then $\text{var}^{|z|=|z| \pm 1} \arg \Delta(z) \to 0$. In the case $\Delta(\pm 1) = 0$ it follows from Theorem 4.9 that

$$\lim_{r_\pm \to 0} \text{var}^{|z| \pm 1} \arg \Delta(z) = \pi.$$ 

Thus relation (5.26) is a direct consequence of (5.27) and (5.28). These arguments prove also the existence of the limits $\xi(1 - 0)$ and $\xi(-1 + 0)$.

6. Scattering theory

6.1. First, we briefly recall basic notions of scattering theory. We refer, for example, to the book [29] for a more complete presentation of this material.

The wave operators $W_{\pm}(H, H_0)$ for a pair of self-adjoint operators $H_0, H$ in a Hilbert space $\mathcal{H}$ are defined as strong limits

$$W_{\pm}(H, H_0) = \text{s-lim}_{t \to \pm \infty} e^{iHt}e^{-iH_0t},$$

(6.1)

here $H_0$ is supposed to be absolutely continuous. Under the assumption of the existence of limits (6.1), $W_{\pm}(H, H_0)$ are isometric operators and enjoy the intertwining property $HW_{\pm}(H, H_0) = W_{\pm}(H, H_0)H_0$. The wave operator $W_{\pm}(H, H_0)$ is called complete if its range coincides with the absolutely continuous subspace of the operator $H$. The scattering operator

$$S = W_+(H, H_0)^*W_-(H, H_0)$$

(6.2)
commutes with $H_0$, $S H_0 = H_0 S$, and it is unitary if both wave operators $W_+(H, H_0)$ and $W_-(H, H_0)$ are complete.

To define the scattering matrix, we suppose for definiteness that the spectrum of $H_0$ is simple and coincides with $[-1, 1]$. Let $F_0 : H \to L^2(-1, 1)$ be unitary and $F_0 H = A F_0$ where $A$ is the operator of multiplication by $\lambda$ in the space $L^2(-1, 1)$. Then the scattering matrix $S(\lambda) \in \mathbb{C}$ is defined by the relation
\[(F_0 S f)(\lambda) = S(\lambda)(F_0 f)(\lambda), \quad \lambda \in (-1, 1); \tag{6.3}\]
obviously, $|S(\lambda)| = 1$ if $S$ is unitary. Note that the scattering matrix does not depend on the diagonalization $F_0$ of $H_0$ if it has simple spectrum.

Let us come back to Jacobi operators. Under condition (1.7) which is always assumed in this section, the perturbation $V = H - H_0$ is trace class. Therefore the wave operators $W_\pm(H, H_0)$ exist and are complete by the classical Kato-Rosenblum theorem.

Our goal here is to obtain representations of the wave operators and of the scattering matrix in terms of the polynomials $P_n(\lambda)$ and of the Jost function $\Omega(\lambda + i0)$ for $\lambda \in (-1, 1)$. Such expressions are known as stationary representations. As a by-product of our considerations, we will also give a direct proof of the existence and completeness of the wave operators.

6.2. Let $d\rho(\lambda)$ be the spectral measure of the operator $H$. We define a mapping $U : \ell^2(\mathbb{Z}_+) \to L^2(\mathbb{R};d\rho)$ by the formula
\[(Ue_n)(\lambda) = P_n(\lambda).\]
This mapping is isometric according to (1.6). It is also unitary because the set of all polynomials $P_n(\lambda)$, $n \in \mathbb{Z}_+$, is dense in $L^2(\mathbb{R};d\rho)$. Finally, the intertwining property
\[(UH f)(\lambda) = \lambda(U f)(\lambda) \tag{6.4}\]
holds. Indeed, it suffices to check it for $f = e_n$ when according to definition (2.1) of the operator $H$, $(UHe_n)(\lambda)$ coincides with the left-hand side of (1.2) (where $z = \lambda$) while $\lambda(Ue_n)(\lambda)$ equals its right-hand side.

Next, we reduce the absolutely continuous part of the operator $H$ to the operator $A$ of multiplication by $\lambda$ in $L^2(-1, 1)$. To that end, we put
\[
\psi_n(\lambda) = \sqrt{w(\lambda)} P_n(\lambda), \quad \lambda \in (-1, 1), \tag{6.5}\]
where $w(\lambda)$ is the weight function defined by (2.30) and introduce a mapping $F : \ell^2(\mathbb{Z}_+) \to L^2(-1, 1)$ by the formula
\[(Fe_n)(\lambda) = \psi_n(\lambda), \quad \lambda \in (-1, 1). \tag{6.6}\]
The operator $F^* : L^2(-1, 1) \to \ell^2(\mathbb{Z}_+)$ adjoint to $F$ is given by the equality
\[(F^* g)_n = \int_{-1}^{1} \psi_n(\lambda) g(\lambda) d\lambda, \quad n \in \mathbb{Z}_+. \tag{6.7}\]
According to (6.5) it follows from the unitarity of the operator $U$ that
\[ FF^* = I, \quad F^* F = E(-1, 1), \quad \text{(6.8)} \]
where $E(-1, 1)$ is the spectral projection of the operator $H$ corresponding to the interval $(-1, 1)$. Thus the operator $F^*$ is isometric, and it is unitary if $H$ has no point spectrum. By virtue of the equation (6.4) the intertwining property
\[ HF^* = F^* A \quad \text{(6.9)} \]
holds.

For the free operator $H_0$, the corresponding unitary mapping $F_0 : \ell^2(\mathbb{Z}_+) \rightarrow L^2(-1, 1)$ is defined by the formula
\[ (F_0 e_n)(\lambda) = \psi_n^{(0)}(\lambda) \quad \text{where} \quad \psi_n^{(0)}(\lambda) = \sqrt{w_{0}(\lambda)} P_n^{(0)}(\lambda), \quad \lambda \in (-1, 1). \quad \text{(6.10)} \]
Here $w_0(\lambda)$ is defined by (2.31) and $P_n^{(0)}(\lambda)$ are normalized Chebyshev polynomials of the second kind.

6.3. The presentation below is very close to Section 4.2 of the book [30] where the continuous case was considered. We start with two elementary facts. Recall that $\zeta(\lambda \pm i0)$ and $\rho_n$ are defined by formulas (2.7) and (2.12), respectively.

**Lemma 6.1.** Let \( \int_{-1}^{1} |g(\lambda)|^2 \sqrt{1 - \lambda^2} d\lambda < \infty \). Then
\[ \lim_{t \to \pm \infty} \sum_{n=0}^{\infty} \left| \int_{-1}^{1} \zeta(\lambda \mp i0)^n e^{-i\lambda t} g(\lambda) d\lambda \right|^2 = 0. \quad \text{(6.11)} \]

**Proof.** It is more convenient to work in the variable $\theta$ using that
\[ \int_{-1}^{1} \zeta(\lambda \mp i0)^n e^{-i\lambda t} g(\lambda) d\lambda = \int_{0}^{\pi} e^{\pm in\theta} e^{-it \cos \theta} g(\cos \theta) \sin \theta d\theta. \quad \text{(6.12)} \]
The Parseval identity implies the uniform in $t$ estimate
\[
\sum_{n=0}^{\infty} \left| \int_{-1}^{1} \zeta(\lambda \mp i0)^n e^{-i\lambda t} g(\lambda) d\lambda \right|^2 \\
\leq 2\pi \int_{0}^{\pi} |g(\cos \theta)|^2 \sin^2 \theta d\theta = 2\pi \int_{-1}^{1} |g(\lambda)|^2 \sqrt{1 - \lambda^2} d\lambda.
\]
Therefore it suffices to check (6.11) for $g \in C_0^\infty((-1, 1))$.

Integrating in (6.12) by parts and observing that
\[ | \pm n + t \sin \theta | \geq c |n + |t|| \quad \text{for} \quad \pm t > 0 \]
where $\theta \in [\varepsilon_0, \pi - \varepsilon_0], \varepsilon_0 > 0$ and $c = c(\varepsilon_0) > 0$, we find an estimate
\[ | \int_{0}^{\pi} e^{\pm in\theta} e^{-it \cos \theta} g(\cos \theta) \sin \theta d\theta | \leq C(n + |t|)^{-1}, \quad n \in \mathbb{Z}_+, \quad \pm t > 0. \]
It follows that
\[
\sum_{n=0}^{\infty} \left| \int_{-1}^{1} \zeta(\lambda \pm i0)^n e^{-i\lambda t} g(\lambda) d\lambda \right|^2 \leq C \sum_{n=0}^{\infty} (n + |t|)^{-2} \leq C_1 |t|^{-1}, \quad \pm t > 0,
\]
which implies (6.11).

\[\square\]

**Lemma 6.2.** Under assumption (1.7), suppose additionally that
\[
\sum_{n=0}^{\infty} \rho_n^2 < \infty.
\]

Let \( g \in L^1(-1, 1) \) and \( \text{supp} \ g \subset (-1, 1) \). Then
\[
\lim_{|t| \to \infty} \sum_{n=0}^{\infty} \left| \int_{-1}^{1} (f_n(\lambda \pm i0) - \zeta(\lambda \pm i0)^n) e^{-i\lambda t} g(\lambda) d\lambda \right|^2 = 0.
\]

**Proof.** Theorem 2.1 yields the estimate
\[
\left| \int_{-1}^{1} (f_n(\lambda \pm i0) - \zeta(\lambda \pm i0)^n) e^{-i\lambda t} g(\lambda) d\lambda \right| \leq C \rho_n
\]
where \( C \) does not depend on \( t \). For every \( n \), the integrals in (6.14) tend to zero as \( |t| \to \infty \) by the Riemann-Lebesgue lemma. So, under assumption (6.13), the dominated convergence theorem implies (6.14).

\[\square\]

Let us now set
\[
\sigma_{\pm}(\lambda) = \Omega(\lambda \pm i0) = e^{\pm in(\arccos \lambda)}, \quad \lambda \in (-1, 1).
\]
The operator \( \Sigma_{\pm}(\lambda) \) of multiplication by \( \sigma_{\pm}(\lambda) \) is of course unitary in the space \( L^2(-1, 1) \).

Using definitions (2.30) and (6.5) of the functions \( w(\lambda) \) and \( \psi_n(\lambda) \), we rewrite relation (2.20) as
\[
\psi_n(\lambda) = \frac{1}{i\sqrt{2\pi} \sqrt{1 - \lambda^2}} \left( -\zeta(\lambda + i0) \sigma_-(\lambda) f_n(\lambda + i0) + \zeta(\lambda - i0) \sigma_+(\lambda) f_n(\lambda - i0) \right). \quad (6.16)
\]

For the operator \( H_0 \) and the function \( \psi_n^{(0)}(\lambda) \) defined in (6.10), this reduces to the formula
\[
\psi_n^{(0)}(\lambda) = \frac{1}{i\sqrt{2\pi} \sqrt{1 - \lambda^2}} \left( -\zeta(\lambda + i0)^n + \zeta(\lambda - i0)^n \right). \quad (6.17)
\]

Recall that the operators \( F \) and \( F_0 \) are defined by relations (6.6) and (6.10). Then \( F^* \) is given by relation (6.7) and similarly for \( F_0^* \). The operator \( A \) acts as multiplication by \( \lambda \) in the space \( L^2(-1, 1) \).

**Lemma 6.3.** For all \( g \in L^2(-1, 1) \), we have
\[
\lim_{t \to \pm \infty} \| (F^* \Sigma_{\pm} - F_0^*) e^{-i\lambda t} g \| = 0. \quad (6.18)
\]
Proof. Since \( \sigma_+(\lambda)\sigma_-(\lambda) = 1 \), it follows from relations (6.16) and (6.17) that, for both signs “±”,

\[
i\sqrt{2\pi} \sqrt{1 - \lambda^2} (\psi_n(\lambda)\sigma_\pm(\lambda) - \psi_n^0(\lambda)) = \pm(\sigma_\pm(\lambda)^2 - 1)\zeta(\lambda \mp i0)^{n+1} + \sigma_\pm(\lambda)r_n(\lambda)
\]

where \( r_n(\lambda) = -r_n^+(\lambda) + r_n^-(\lambda) \) and

\[
r_n^{(\pm)}(\lambda) = \zeta(\lambda \pm i0)\sigma_\pm(\lambda)(f_n(\lambda \pm i0) - \zeta(\lambda \pm i0)^{n+1}).
\]

According to (6.19) we have

\[
(F^*\Sigma_\pm - F_0^*)e^{-i\lambda t}g)_n = \pm \int_{-1}^1 (\sigma_\pm(\lambda)^2 - 1)\zeta(\lambda \mp i0)^{n+1}\tilde{g}(\lambda)d\lambda + \int_{-1}^1 r_n(\lambda)\sigma_\pm(\lambda)e^{-i\lambda t}\tilde{g}(\lambda)d\lambda
\]

where

\[
\tilde{g}(\lambda) = \frac{g(\lambda)}{i\sqrt{2\pi} \sqrt{1 - \lambda^2}}.
\]

Let us come back to relation (6.18) where we may assume that \( \text{supp} \ g \subset (-1, 1) \). If \( t \to +\infty \) (if \( t \to -\infty \)), we use (6.20) for the upper (lower) sign. Then the contribution to the norm in \( \ell^2(\mathbb{Z}_+) \) of the first term in the right-hand side of (6.20) tends to zero according to Lemma 6.1. The contribution of the second term tends to zero according to Lemma 6.2.

\[\square\]

**Theorem 6.4.** Let assumptions (1.7) and (6.13) be satisfied. Then the strong limits (6.1) exist and

\[
W_\pm(H, H_0) = F^*\Sigma_\pm F_0.
\]

Proof. We have to check that

\[
\lim_{t \to \pm\infty} \|e^{iHt}e^{-iH_0t}f - F^*\Sigma_\pm F_0f\| = 0
\]

for all \( f \in \ell^2(\mathbb{Z}_+) \). In view of the intertwining property (6.9) this relation can be rewritten as

\[
\lim_{t \to \pm\infty} \|e^{-iH_0t}f - F^*\Sigma_\pm e^{-iAt} F_0f\| = 0.
\]

Set now \( g = F_0f \). Then again in view of the intertwining property (6.9) for \( H_0 \), we see that relations (6.18) and (6.22) are equivalent.

\[\square\]

It follows from relations (6.8) and (6.21) that the scattering operator (6.2) is given by the equality

\[
S = F_0^*\Sigma_+^\dagger \Sigma_- F_0.
\]

Putting together this relation with the definition (6.3) of the scattering matrix and definition (6.15) of \( \sigma_\pm(\lambda) \), we can state the following result. Recall also that the scattering phase \( \eta(\theta) \) was defined by formula (2.22).
Theorem 6.5. Under assumptions of Theorem 6.4, the scattering matrix for the pair $H_0, H$ satisfies the equality

$$S(\lambda) = \frac{\Omega(\lambda - i\theta)}{\Omega(\lambda + i\theta)} = e^{-2i\eta(\arccos \lambda)}, \quad \lambda \in (-1, 1). \quad (6.23)$$

In view of relation (5.23), formula (6.23) can be rewritten as the Birman-Kreĭn formula

$$S(\lambda) = e^{-2i\pi \xi(\lambda)}.$$  

6.4. Theorems 6.4 and 6.5 remain true without additional assumption (6.13). The proof of this fact requires some tools of abstract scattering theory. We give only basic ideas of one of its possible proofs.

The following result is a direct consequence of Theorem 3.2.

Lemma 6.6. Let an operator $Q$ in the space $\ell^2(\mathbb{Z}_+)$ be defined by the equality $(Qf)_n = q_n f_n$ where $q_n = \bar{q}_n$ and $\sum_{n=0}^{\infty} q_n^2 < \infty$. Under assumption (1.7) the operator-valued function $QR(z)Q$ defined for $\text{Im} \ z \neq 0$ is continuous in the Hilbert-Schmidt norm up to the cut along $[-1, 1]$ with possible exception of the points $z = \pm 1$. In particular, the operator $Q$ is $H$-smooth in the sense of Kato on every compact subinterval of $(-1, 1)$.

Under assumption (1.7) Lemma 6.6 is true with $q_n = (|a_n - 1/2| + |b_n|)^{1/2}$.

Note that the perturbation $V = QGQ$ where $G$ is a bounded operator in the space $\ell^2(\mathbb{Z}_+)$. Using Theorems 5.3.4 and 5.6.1 in [29], we can now deduce from Lemma 6.6 the following assertion.

Theorem 6.7. The wave operators $W_{\pm}(H, H_0)$ exist, are complete and representations (6.21), (6.23) are true under the only assumption (1.7).

7. The Szegö function and the Case sum rules

Here we establish a link between the perturbation determinant $\Delta(z)$ and the Szegö function $D(\zeta)$. We also show that the Case sum rules are direct consequences of this link. Since the Jost function $\Omega(z)$ is related to $\Delta(z)$ by simple formula (5.19), we do not discuss it here. As usual, $|\zeta| < 1$ and $2z = \zeta + \zeta^{-1}$.

7.1. We define the Szegö function $D(\zeta)$ by the formula

$$D(\zeta) = \exp \left( \frac{1}{4\pi} \int_{-\pi}^{\pi} e^{i\theta} + \zeta \ln \left( w(\cos \theta)|\sin \theta| \right) d\theta \right), \quad |\zeta| < 1, \quad (7.1)$$

where $w(\lambda)$ is the weight function (2.29). This is exactly formula (10.2.10) (see also Theorem 12.1.2) in [26], but in contrast to [26] we do not suppose that $H$ has no
eigenvalues. Of course definition (7.1) requires that
\[ \int_{-\pi}^{\pi} |\ln(w(\cos \theta)| \sin \theta)| d\theta < \infty \]
or, equivalently, (1.8) be satisfied. This is known as the Szegö condition.

Recall the standard Jensen-Poisson representation of functions \( f(\zeta) \) analytic in the unit disc \( |\zeta| < 1 \). If \( f(\zeta) \) is continuous in the closed disc \( |\zeta| \leq 1 \) and \( \text{Im} f(0) = 0 \), then
\[ f(\zeta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{i\theta} + \zeta e^{i\theta} - \zeta \text{Re} f(e^{i\theta}) d\theta. \] (7.2)

In particular, we see that
\[ \ln(1 + \zeta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{i\theta} + \zeta e^{i\theta} - \zeta \ln \cos(\theta/2) d\theta, \]
\[ \ln(1 - \zeta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{i\theta} + \zeta e^{i\theta} - \zeta \ln |\sin(\theta/2)| d\theta. \] (7.3)

We here fix \( \text{arg}(1 + \zeta) \) and \( \text{arg}(1 - \zeta) \) by the condition \( \text{arg} 1 = 0 \).

Set \( \tilde{\Delta}(\zeta) = \Delta(z) \). It follows from Corollary 2.2 that the function \( \tilde{\Delta}(\zeta) \) is analytic in the unit disc and is continuous up to the unit circle with a possible exception of the points \( \pm 1 \). Moreover, according to (2.21), \( \tilde{\Delta}(\zeta) \neq 0 \) if \( |\zeta| = 1 \) but \( \zeta \neq \pm 1 \).

Under assumption (1.7), an information on the behavior of \( \tilde{\Delta}(\zeta) \) as \( \zeta \to \pm 1 \) follows from Theorem 9.14 in [20] where it is shown that the function \( \tilde{\Delta}(\zeta) \) belongs to the Nevanlinna class \( N \) and does not have a singular inner component. We refer to the book [8], Chapter 2, for precise definitions of these notions. We also note that \( \tilde{\Delta}(0) = 1 \) according to (5.2).

Let \( \lambda_k \) be eigenvalues (lying on \( (-\infty, -1) \cup (1, \infty) \)) of the operator \( H \). In contrast to Subsection 5.5, we do not distinguish positive and negative eigenvalues in notation and suppose that \( |\lambda_1| \geq |\lambda_2| \geq \cdots > 1 \). The numbers \( \mu_k \in (-1, 1) \) defined by
\[ \mu_k + \mu_k^{-1} = 2\lambda_k \]
are zeros of the function \( \tilde{\Delta}(\zeta) \). Since \( \tilde{\Delta} \in N \), we have
\[ \sum_{k=1}^{\infty} (1 - |\mu_k|) < \infty, \] (7.4)
so that the Blaschke product
\[ B(\zeta) = \prod_{k=1}^{\infty} \frac{\mu_k - \zeta}{|\mu_k| - \mu_k \zeta}, \quad |\zeta| < 1, \] (7.5)
is well defined. The function \( B(\zeta) \) is continuous in the closed disc \( |\zeta| \leq 1 \) except, possibly, the points \( \pm 1 \) and \( |B(\zeta)| = 1 \) for \( |\zeta| = 1 \). Note that the proof of the inclusion \( \tilde{\Delta} \in N \) in [20] relied on the condition (7.4) established under assumption (1.7) earlier in [18].
Let us define the outer function

$$G(\zeta) = \exp \left( \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{e^{i\theta} + \zeta}{e^{i\theta} - \zeta} \ln |\bar{\Delta}(e^{i\theta})| d\theta \right)$$

(7.6)

where the function $\ln |\bar{\Delta}(e^{i\theta})|$ belongs to $L^1(-\pi, \pi)$ because $\bar{\Delta} \in N$. This is equivalent to the Szegö condition (1.8) since, by relations (2.30) and (5.19),

$$|\bar{\Delta}(e^{i\theta})|^2 = |\Delta(\cos \theta)|^2 = A^2 \frac{2}{\pi w(\cos \theta)}$$

whence

$$2 \ln |\bar{\Delta}(e^{i\theta})| = -\ln(w(\cos \theta)|\sin \theta|) + \ln(2\pi^{-1}A^2 \sin^2 \theta).$$

(7.7)

It follows from Theorem 2.9 in [8] that the factorization

$$\bar{\Delta}(\zeta) = B(\zeta)G(\zeta)$$

(7.8)

holds. Of course (7.6) is the Jensen-Poisson representation (7.2) of the function $f(\zeta) = \ln (\bar{\Delta}(\zeta)/B(\zeta))$, but, since this function is not continuous in the disc $|\zeta| \leq 1$, its justification relies on the properties of $\bar{\Delta}$ stated above.

Let us now compare definitions (7.1) and (7.6). We substitute expression (7.7) into (7.1) and take into account formulas (7.3). Thus, using factorization (7.8), we arrive at the following result.

**Theorem 7.1.** Let assumption (1.7) be satisfied, and let $|\zeta| < 1$. Set $\bar{\Delta}(\zeta) = \Delta(2^{-1}(\zeta + \zeta^{-1}))$ where $\Delta(z)$ is the perturbation determinant (5.1). Define the Blaschke product $B(\zeta)$ by formula (7.5), the Szegö function $D(\zeta)$ – by (7.1), and the product $A$ – by (5.20). Then the identity

$$\bar{\Delta}(\zeta) = AB(\zeta) \frac{1 - \zeta^2}{\sqrt{2\pi D(\zeta)}}$$

(7.9)

is true.

We emphasize that Theorem 7.1 is a direct consequence of classical results on the factorization of functions in the Nevanlinna class combined with the analytical results of [20].

According to (7.9) formulas (5.7) and (7.1) provide two different representations of an essentially the same object named the perturbation determinant $\Delta(z)$ or the Szegö function $D(\zeta)$. In view of (5.5) the first of them is given in terms of $\arg \Delta(\lambda + i0)$ while according to (2.30) and (5.19) the second representation is stated in terms of $\ln |\Delta(\lambda + i0)|$. Obviously, these two functions are harmonic conjugate.

It is of course possible to rewrite representation (7.1) in terms of the variable $z = 2^{-1}(\zeta + \zeta^{-1}) \in \Pi$. Let us also introduce the weight function $w_0(\lambda)$ of the operator $H_0$; it is given by formula (2.31). Taking into account that the function $w(\cos \theta)|\sin \theta|$ is
even, making the change of variables \( \lambda = \cos \theta \) and using formulas (7.3), we see that

\[
D(\zeta) = \frac{1 - \zeta^2}{\sqrt{2\pi}} \exp \left( \frac{1 - \zeta^2}{2\pi} \int_{-1}^{1} \ln \left( \frac{w(\lambda)/w_0(\lambda)}{1 - 2\zeta \lambda + \zeta^2} \right) \frac{d\lambda}{\sqrt{1 - \lambda^2}} \right) \tag{7.10}
\]

or, equivalently,

\[
D(\zeta(z)) = \zeta(z) \sqrt{\frac{2(z^2 - 1)}{\pi}} \exp \left( - \frac{\sqrt{z^2 - 1}}{2\pi} \int_{-1}^{1} \ln \left( \frac{w(\lambda)/w_0(\lambda)}{\lambda - z} \right) \frac{d\lambda}{\sqrt{1 - \lambda^2}} \right).
\]

7.2. Let us, finally, obtain the Case sum rules for the pair \( H_0, H \). Putting together (7.9) and (7.10), we see that

\[
\ln \tilde{\Delta}(\zeta) - \ln B(\zeta) - \ln A = \frac{\zeta^2 - 1}{2\pi} \int_{-1}^{1} \ln \left( \frac{w(\lambda)/w_0(\lambda)}{1 - 2\zeta \lambda + \zeta^2} \right) \frac{d\lambda}{\sqrt{1 - \lambda^2}}. \tag{7.11}
\]

Let us compare the behavior of both sides of this equation as \( \zeta \to 0 \). Since \( \tilde{\Delta}(0) = 1 \), setting \( \zeta = 0 \) and using definition (7.5), we obtain the identity

\[
\sum_{k=1}^{\infty} \ln(2a_k) + \sum_{k=1}^{\infty} \ln |\mu_k| = \frac{1}{2\pi} \int_{-1}^{1} \ln \left( \frac{w(\lambda)/w_0(\lambda)}{\lambda - 1} \right) \frac{d\lambda}{\sqrt{1 - \lambda^2}}. \tag{7.12}
\]

This Case sum rule of zero order is of course different from the Levinson theorem (5.26).

More generally, let us consider the asymptotic expansions of both sides of (7.11) as \( \zeta \to 0 \) and compare the coefficients at the same powers of \( \zeta \). According to Theorem 2.13 in [20] we have

\[
\ln \tilde{\Delta}(\zeta) = -2 \sum_{n=1}^{\infty} n^{-1} \text{Tr} \left( T_n(H) - T_n(H_0) \right) \zeta^n
\]

where \( T_n(\lambda) = \cos(n \arccos \lambda) \) are the Chebyshev polynomials of the first kind. It directly follows from definition (7.5) that

\[
\ln B(\zeta) = \sum_{k=1}^{\infty} \ln |\mu_k| + \sum_{n=1}^{\infty} n^{-1} \left( \sum_{k=1}^{\infty} (\mu_k^n - \mu_k^{-n}) \right) \zeta^n
\]

where the series over \( k \) are convergent due to the condition (7.4). Finally, we use formula (10.11.29) in [9]:

\[
\frac{1 - \zeta^2}{1 - 2\zeta \lambda + \zeta^2} = 1 + 2 \sum_{n=1}^{\infty} T_n(\lambda) \zeta^n.
\]
Thus the equality of the coefficients at \( \zeta^n \) in the left- and right-hand sides of (7.11) yields the identity

\[
\text{Tr} \left( T_n(H) - T_n(H_0) \right) = -\frac{1}{2} \sum_{k=1}^{\infty} (\mu_k^n - \mu_{-k}^{-n}) \]

\[
+ \frac{n}{2\pi} \int_{-1}^{1} \ln \left( w(\lambda) / w_0(\lambda) \right) T_n(\lambda) \frac{d\lambda}{\sqrt{1 - \lambda^2}}, \quad n = 1, 2, \ldots
\]

(7.13)

The trace identities (7.12) and (7.13) known as the Case sum rules are not new. They were obtained by him in [5] and rigorously proven in [20]. We note that, in the paper [20], the identities (7.12) and (7.13) were first checked for finite rank perturbations \( H - H_0 \) and then (7.12) and (7.13) (for \( n = 1 \)) were used for the proof of the inclusion \( \tilde{\Delta} \in \mathcal{N} \).

7.3. The Szegö condition (1.8) implies that the weight function \( w(\lambda) \) does not vanish too rapidly as \( \lambda \to -1 \) and \( \lambda \to 1 \) or, to put it differently, \( |\Omega(\lambda + i0)| \) does not tend to infinity too rapidly. The example of the Pollaczek polynomials shows that condition (1.8) may be violated without assumption (1.7).

Recall that the normalized Pollaczek polynomials are defined (see, e.g., Appendix to [26]) by recurrent relations (1.2) with

\[
a_n = \frac{n + 1}{\sqrt{(2n + 2\alpha + 1)(2n + 2\alpha + 3)}}, \quad b_n = -\frac{2\beta}{2n + 2\alpha + 1};
\]

(7.14)

here the parameters \( \alpha, \beta \in \mathbb{R} \) and \( \alpha > |\beta| \). It follows that

\[
a_n = 2^{-1} - \alpha(2n)^{-1} + O(n^{-2}), \quad b_n = -\beta n^{-1} + O(n^{-2}).
\]

(7.15)

The corresponding normalized weight function is given by the formula

\[
w(\lambda) = (\alpha + 1/2)e^{(2\theta - \pi)h(\theta)} (\cosh(\pi h(\theta)))^{-1} \quad \text{where} \quad h(\theta) = (\alpha \cos \theta + \beta)(\sin \theta)^{-1}
\]

and as usual \( \lambda = \cos \theta \). It is easy to see that

\[
\ln w(\lambda) = -\pi(\alpha + \beta)\theta^{-1} + O(1)
\]

(7.16)

as \( \lambda \to 1 - 0 \) and a similar formula is true as \( \lambda \to -1 + 0 \).

It follows from (7.15) that \( V = H - H_0 \) is Hilbert-Schmidt, but the series \( \sum_n (a_n - 1/2) \) and \( \sum_n b_n \) are divergent; in particular, assumption (1.7) is not satisfied. According to (7.16) the Szegö condition (1.8) is violated for Pollaczek polynomials. This is consistent with the classical theorem of Szegö, Shohat, Geronimus, Krein and Kolmogorov; see, e.g., Theorem 4 in [20]. On the other hand, relation (7.16) implies that

\[
\int_{-1}^{1} \ln w(\lambda) (1 - \lambda^2)^{1/2} d\lambda > -\infty.
\]

This is consistent with Theorem 1 in [20].
7.4. For the continuous operator \( H = -D^2 + b(x) \), an analogue of the Szegő condition means that the corresponding weight function \( w(\lambda) \) (for its definition, see, e.g., subsection 6 of § 4.1 in [30]) does not vanish too rapidly as \( \lambda \to +0 \), that is,

\[
\int_0^1 \ln w(\lambda) \lambda^{-\alpha} d\lambda > -\infty
\]  

(7.17)

where \( \alpha = 1/2 \) if \( b \in L^1(\mathbb{R}_+) \). Note however that we were unable to find this assertion in the literature.

Condition (7.17) appears to be sufficiently sharp. Indeed, suppose that \( b \) is a non-negative smooth function such that

\[
b(x) = b_0 x^{-\rho}, \quad b_0 > 0, \quad \rho \in (0, 2),
\]

for large \( x \). It is shown in [28] that for such potentials

\[
\ln w(\lambda) \sim -w_0 \lambda^{-(2-\rho)/(2\rho)}, \quad w_0 = w_0(b_0, \rho) > 0,
\]

as \( \lambda \to +0 \). In this case condition (7.17) is satisfied if and only if \( \alpha < 3/2 - 1/\rho \). Observe that formula (7.16) for Pollaczek polynomials corresponds to the exponential decay as \( \lambda \to 0 \) of the weight function \( w(\lambda) \) for Coulomb repulsive potentials.

The trace class condition for the operator \( H \) requires that \( \rho > 1 \) which yields (7.17) for any \( \alpha < 1/2 \). Similarly, the Hilbert-Schmidt condition for the operator \( H \) requires that \( \rho > 1/2 \) which yields (7.17) for any \( \alpha < -1/2 \). This is very close to the so-called quasi-Szegő condition established in [20] for the Jacobi operator \( H = H_0 + V \) with a Hilbert-Schmidt perturbation \( V \).

8. Example. The Jacobi polynomials

8.1. In this section we suppose that the measure \( d\rho(\lambda) \) is absolutely continuous and supported on the interval \([-1, 1]\) so that

\[
d\rho(\lambda) = w(\lambda) d\lambda, \quad \lambda \in (-1, 1),
\]

(8.1)

and

\[
w(\lambda) = \kappa (1 - \lambda)^\alpha (1 + \lambda)^\beta, \quad \alpha, \beta > -1.
\]

(8.2)

The weight function \( w(\lambda) = w_{\alpha,\beta}(\lambda) \) (as well as all other objects discussed below) depends on \( \alpha \) and \( \beta \), but these parameters are often omitted in notation. The constant

\[
\kappa = \kappa_{\alpha,\beta} = \frac{\Gamma(\alpha + \beta + 2)}{2^{\alpha + \beta + 1} \Gamma(\alpha + 1) \Gamma(\beta + 1)}
\]

(8.3)

is chosen in such a way that the measure (8.1) is normalized, i.e., \( \rho(\mathbb{R}) = \rho((-1, 1)) = 1 \). The orthonormal polynomials \( P_n(\lambda) = P_n^{(\alpha,\beta)}(\lambda) \) constructed by the measure (8.1), (8.2) are known as the Jacobi polynomials.
Usually the Jacobi polynomials $P_n(\lambda) = P_n^{(\alpha, \beta)}(\lambda)$ are normalized (see, e.g., the books [9, 26]) by the condition

$$P_n(1) = \frac{\Gamma(\alpha + 1 + n)}{\Gamma(\alpha + 1)\Gamma(n + 1)}.$$  

(8.4)

According to formulas (10.8.4) and (10.8.5) in the book [9] we have

$$\int_{-1}^1 |P_n(\lambda)|^2 (1 - \lambda)^\alpha (1 + \lambda)^\beta d\lambda = \frac{2^{\alpha + \beta + 1}\Gamma(\alpha + 1 + n)\Gamma(\beta + 1 + n)}{n!(2n + \alpha + \beta + 1)\Gamma(\alpha + \beta + n + 1)} =: h_n$$

(8.5)

and

$$P_n(z) = k_n(z^n + \frac{n(\alpha - \beta)}{2n + \alpha + \beta}z^{n-1} + \cdots)$$

where

$$k_n = \frac{\Gamma(\alpha + \beta + 2n + 1)}{2^n n!\Gamma(\alpha + \beta + n + 1)}.$$  

(8.6)

For $\alpha + \beta \leq -1$ and $n = 0$, we have to set

$$h_0 = 2^{\alpha + \beta + 1} \frac{\Gamma(\alpha + 1)\Gamma(\beta + 1)}{\Gamma(\alpha + \beta + 2)} = \kappa^{-1} \quad \text{and} \quad k_0 = 1.$$  

(8.7)

It follows from equalities (8.2) and (8.5) that

$$P_n(z) = (\kappa h_n)^{-1/2}P_n(z).$$

Let $H$ be the Jacobi operator corresponding to the measure (8.1), (8.2). Its coefficients are given by formulas (1.4) which yields

$$a_n^2 = \frac{k_n^2}{h_{n+1}} \frac{h_n}{h_n} = \frac{4(n+1)(n+\alpha+1)(n+\beta+1)}{(2n+\alpha+\beta+3)(2n+\alpha+\beta+2)^2} \frac{n+\alpha+\beta+1}{2n+\alpha+\beta+1}$$

(8.8)

(if $n = 0$ and $\alpha + \beta = -1$ the last factor here should be replaced by 1) and

$$b_n = (\alpha - \beta)\left(\frac{n}{2n+\alpha+\beta} - \frac{n+1}{2n+2+\alpha+\beta}\right)$$

(8.9)

(if $n = 0$ and $\alpha + \beta = 0$ this formula should be replaced by $b_0 = (\beta - \alpha)/2$). Obviously, for a symmetric weight function (8.2) when $\alpha = \beta$, we have $b_n = 0$. In the general case, we have the asymptotic formulas

$$a_n = 1/2 + 2^{-1}(1 - 2\alpha^2 - 2\beta^2)n^{-2} + O(n^{-3}), \quad b_n = 2^{-2}(\beta^2 - \alpha^2)n^{-2} + O(n^{-3}).$$  

(8.10)

Assumption (1.7) is of course true in this case, and the sequence (2.12) satisfies the condition $\rho_n = O(n^{-1})$ as $n \to \infty$. Note that the coefficients at $n^{-2}$ in (8.10) are not zeros unless $|\alpha| = |\beta| = 1/2$. 

Next, we calculate the product (5.20). It follows from (8.8) that
\[
A^{(n)} := \prod_{k=0}^{n-1} (2a_k) = \frac{k_0}{\sqrt{h_0}} \frac{\sqrt{h_n}}{k_n} 2^n.
\]
Let us find the limit of the right-hand side as \( n \to \infty \). According to formula (1.18.4) in the book [9], for all \( p \in \mathbb{R} \) we have
\[
\Gamma(n + p) = n^p \Gamma(n)(1 + O(n^{-1})).
\] (8.11)
Therefore the sequence \( h_n \) defined by (8.5) satisfies
\[
h_n = 2^{\alpha + \beta} n^{-1} + O(n^{-2}).
\] (8.12)
Let us use additionally (see formula (1.3.11) in [9]) that
\[
\Gamma(2n + \alpha + \beta + 1) = \pi^{-1/2} 2^{2n + \alpha + \beta} \Gamma(n + (\alpha + \beta + 1)/2) \Gamma(n + (\alpha + \beta + 2)/2).
\]
So, we see that the sequence \( k_n \) defined by (8.6) satisfies \( k_n = 2^{\alpha + \beta} 2^n (\pi n)^{-1/2} (1 + O(n^{-1})) \). It follows that
\[
\lim_{n \to \infty} 2^n \frac{\sqrt{h_n}}{k_n} = \sqrt{\pi} 2^{-(\alpha + \beta)/2}.
\]
Taking also into account formulas (8.7), we finally find that
\[
A = \lim_{n \to \infty} A^{(n)} = \sqrt{\pi} \kappa 2^{-(\alpha + \beta)/2}
\] (8.13)
where \( \kappa \) is defined by (8.3).

**8.2.** Let us calculate the Szegő function defined by (7.1) for the measure (8.1), (8.2). Now we have
\[
w(\cos \theta | \sin \theta) = \kappa 2^{\alpha + \beta + 1} | \sin(\theta/2)|^{2\alpha + 1} (\cos(\theta/2))^{2\beta + 1}.
\]
Substituting this expression into (7.1) and using relations (7.3), we find that
\[
D(\zeta) = \sqrt{\kappa} 2^{-(\alpha + \beta + 1)/2} (1 - \zeta)^{\alpha + 1/2} (1 + \zeta)^{\beta + 1/2}.
\] (8.14)
In particular, for the operator \( H_0 \) when \( \alpha = \beta = 1/2 \), we have \( D_0(\zeta) = (2\pi)^{-1/2} (1 - \zeta^2) \). Setting in (8.14) \( \zeta = 0 \) and taking into account that, by (7.9), \( \sqrt{2\pi} D(0) = A \), we recover expression (8.13).

Now the perturbation determinant (5.1) for the pair \( H_0, H \) can be found from formulas (7.9) where \( B(\zeta) = 1 \) and (8.13), (8.14). Let us state the results obtained.

**Theorem 8.1.** Let \( H \) be the Jacobi operator with the coefficients (8.8), (8.9) or, equivalently, corresponding to the spectral measure (8.1), (8.2). Then the Szegő function \( D(\zeta) \) and the perturbation determinant \( \Delta(z) \) are given by formulas (8.14) and
\[
\Delta(z) = (1 - \zeta(z))^{-\alpha + 1/2} (1 + \zeta(z))^{-\beta + 1/2}.
\] (8.15)
Recall that the Jost function \( \Omega(z) \) is related to \( \Delta(z) \) by formula (5.19). So it follows from Theorem 3.5 that
\[
\lim_{n \to \infty} \zeta(z)^n P_n(z) = \kappa^{-1/2} \pi^{-1/2} 2^{(\alpha+\beta)/2} (1 - \zeta(z))^{-\alpha-1/2} (1 + \zeta(z))^{-\beta-1/2}, \quad z \in \Pi.
\]

Thus we recover the well known asymptotic formula (see, for example, formula (8.21.9) in the book [26]) for the Jacobi polynomials.

Let us now calculate \( \Omega(\lambda + i0) \) for \( \lambda \in (-1, 1) \); as usual, we set \( \lambda = \cos \theta \) where \( \theta \in (0, \pi) \). Then \( \zeta = \zeta(\lambda + i0) = e^{-i\theta} \) belongs to the lower half-circle. It is easy to see that
\[
1 - \zeta = 1 - \cos \theta + i \sin \theta = 2 \sin(\theta/2) e^{i(\pi-\theta)/2} = \sqrt{2(1 - \lambda)} e^{i(\pi-\theta)/2}
\]
and
\[
1 + \zeta = 1 + \cos \theta - i \sin \theta = 2 \cos(\theta/2) e^{-i\theta/2} = \sqrt{2(1 + \lambda)} e^{-i\theta/2}.
\]
Substituting these expressions into formula (8.15) we obtain the following result.

**Theorem 8.2.** Under the assumptions of Theorem 8.1, the perturbation determinant is given on the cut along \([-1, 1]\) by the formula
\[
\Delta(\lambda + i0) = 2^{(1-\alpha-\beta)/2} (1 - \lambda)^{(1-2\alpha)/4} (1 + \lambda)^{(1-2\beta)/4} e^{i\pi \xi(\lambda)}, \quad \lambda \in (-1, 1),
\]
where the spectral shift function
\[
\xi(\lambda) = (2\pi)^{-1} (\alpha + \beta - 1) \arccos \lambda - 4^{-1} (2\alpha - 1).
\]

Using (5.19), (8.13) and substituting expression (8.16) for \( |\Delta(\lambda + i0)| \) into formula (2.30), we recover relations (8.2), (8.3) for \( w(\lambda) \). In view of definition (2.22), Theorem 8.2 yields expressions for the limit amplitude and the limit phase. Thus, formula (2.23) means that
\[
P_n(\lambda) = 2^{1/2} (\pi \kappa)^{-1/2} (1 - \lambda)^{-(1+2\alpha)/4} (1 + \lambda)^{-(1+2\beta)/4} \\
\times \sin \left( (n + \frac{\alpha + \beta + 1}{2}) \arccos \lambda - \frac{2\alpha - 1}{4} \pi \right) + O(n^{-1})
\]
where \( \kappa \) is given by (8.3). This coincides of course with asymptotics (8.21.10) of the Jacobi polynomials in the book [26].

Substituting expressions (8.15) for the perturbation determinant and (8.17) for the spectral shift function into formula (5.7) we obtain a curious identity
\[
\int_{-1}^{1} \frac{\arccos \lambda}{\lambda - z} d\lambda = -2\pi \ln(1 + \zeta(z)).
\]

The asymptotics of Jacobi polynomials at the edge points \( z = \pm 1 \) is different from general results (4.7) and (4.9) of Section 4 because in view of formulas (8.9) and (8.10) the condition (4.1) is not satisfied unless \( |\alpha| = |\beta| = 1/2 \). Indeed, putting together formulas (8.4), (8.11) and (8.12), we see that
\[
P_n(1) = \kappa^{-1/2} \Gamma(\alpha + 1)^{-1} 2^{-(\alpha+\beta)/2} n^{\alpha+1/2} (1 + O(n^{-1}))
\]
(8.18)
where $\kappa$ is defined by (8.3). This is consistent with asymptotics (4.7) if $\alpha = 1/2$ and with asymptotics (4.9) if $\alpha = -1/2$. The results for $P_n(-1)$ are quite similar.

8.3. Let us now discuss stationary representations for the wave operators $W_{\pm}(H, H_0)$ and the corresponding scattering matrix $S(\lambda)$. Recall that the operator $F$ was defined by equations (6.5) and (6.6). Using formulas (6.15) and (6.23), we can state the following result.

**Theorem 8.3.** Under the assumptions of Theorem 8.1, the wave operator $W_{\pm}(H, H_0)$ is given by the equality (6.21) where $\Sigma_\pm$ is the operator of multiplication by the function

$$\sigma_\pm(\lambda) = e^{\pm i(\alpha + \beta - 1)\arccos \lambda - \pi(\alpha - 1/2)/2}.$$ 

The scattering matrix satisfies the equation

$$S(\lambda) = e^{i\pi(\alpha - 1/2)} e^{-i(\alpha + \beta - 1)\arccos \lambda},$$

In view of asymptotics (8.10) the condition (4.1) is not satisfied (unless $|\alpha| = |\beta| = 1/2$), and hence the results of Subsections 4.1 and 4.2, as well as Theorem 5.10, are not applicable. Nevertheless representation (8.15) allows us to find the singularity of the perturbation determinant $\Delta(z)$ as $z \to \pm 1$. If $z \to 1$, then

$$\Delta(z) = 2^{-\beta + 1/2}(1 - \zeta(z))^{-\alpha + 1/2}(1 + O(|\zeta(z) - 1|)).$$

If $z \to -1$, we have

$$\Delta(z) = 2^{-\alpha + 1/2}(1 + \zeta(z))^{-\beta + 1/2}(1 + O(|\zeta(z) + 1|)).$$

It follows from (8.17) that the limits of $\xi(\lambda)$ as $\lambda \to -1 + 0$ and as $\lambda \to 1 - 0$ exist and

$$\xi(-1 + 0) = (1 - 2\beta)/4, \quad \xi(1 - 0) = (1 - 2\alpha)/4.$$ 

Recall that $\xi(\lambda) = 0$ for $|\lambda| > 1$. Thus, the spectral shift function is continuous at the point $-1$ (at the point 1) if and only if $\beta = 1/2$ ($\alpha = 1/2$). We are not aware of the results of this type for the differential operator $D\alpha(x)D + b(x)$ in the space $L^2(\mathbb{R})$.

Let us, finally, discuss the exceptional case $|\alpha| = |\beta| = 1/2$:

1. If $\alpha = \beta = 1/2$, then $a_n = 1/2$, $b_n = 0$ for all $n \in \mathbb{Z}_+$, and hence $H = H_0$.

2. If $\alpha = \beta = -1/2$, then $a_0 = 1/\sqrt{2}$, $a_n = 1/2$ for all $n \geq 1$, $b_n = 0$ for all $n \in \mathbb{Z}_+$ and the perturbation $V$ has rank 2. In this case, $\Delta(z) = 1 - \zeta(z)^2$ so that the corresponding Jacobi operator has resonances at both points $z = 1$ and $z = -1$.

3. If $\alpha = -\beta = \pm 1/2$, then $a_n = 1/2$ for all $n \in \mathbb{Z}_+$, $b_0 = \mp 1$, $b_n = 0$ for all $n \geq 1$ and the perturbation $V$ has rank 1. In this case, $\Delta(z) = 1 \pm \zeta(z)$ so that the corresponding Jacobi operator has a resonance at the point $z = \mp 1$.

Observe that in cases 1 and 2, $P_n(\lambda)$ are the normalized Chebyshev polynomials of the second and first kind, respectively.

8.4. Note that very detailed results on the asymptotics of the orthogonal polynomials were obtained in [21] for the weight function

$$\tilde{w}(\lambda) = (1 - \lambda)^\alpha (1 + \lambda)^\beta h(\lambda);$$
here \( h(\lambda) \) is an arbitrary real analytic function such that \( h(\lambda) > 0 \) for \( \lambda \in [-1, 1] \). On the contrary, it was shown in [23] that, for the weight function \( \bar{w}(\lambda) \chi_c(\lambda) \) where \( \chi_c(\lambda) = 1 \) for \( \lambda \in [-1, 0) \) and \( \chi_c(\lambda) = c \neq 1, c > 0 \), for \( \lambda \in (0, 1] \), the classical asymptotics (1.9) of the orthogonal polynomials is significantly changed. For such weight functions, \( a_n - 1/2 = O(n^{-1}) \) and \( b_n = O(n^{-1}) \) so that condition (1.7) is not satisfied.

Both papers [21] and [23] rely on the approach of [14, 7].

**Appendix A. Discrete Volterra equations**

**A.1.** Here we prove Theorems 2.1 and 2.3. We follow rather closely the scheme exposed for the Schrödinger equation in a detailed way in Section 4.1 of [30]. Note however that the operator \( H \) is obtained by a second order perturbation of the operator \( \mathcal{H}_0 \). This circumstance should be taken into account.

Let us reduce equation (2.2) to a discrete Volterra integral equation.

**Lemma A.1.** Let assumption (1.7) be satisfied, and let \( z \in \text{clos} \Pi, z \neq \pm 1 \). Suppose that \( f(z) = \{f_n(z)\} \in \ell^\infty(\mathbb{Z}_+) \) and define \( V \) by formula (2.10). Then a solution of the equation (2.11) satisfies also equation (2.2).

**Proof.** Under assumption (1.7), the sequence \( \phi(z) := Vf(z) \in \ell^1(\mathbb{Z}_+) \). Put

\[
\Sigma_n^+(z) = \sum_{m=n+1}^\infty \zeta(z)^m \phi_m(z), \quad \Sigma_n^-(z) = \sum_{m=n+1}^\infty \zeta(z)^{-m} \phi_m(z).
\]

Then equation (2.11) can be written as

\[
f_n = \zeta^n - \frac{\zeta^n}{\sqrt{z^2 - 1}} \Sigma_n^- + \frac{\zeta^{-n}}{\sqrt{z^2 - 1}} \Sigma_n^+,
\]

whence

\[
f_{n-1} = \zeta^{n-1} - \frac{\zeta^{n-1}}{\sqrt{z^2 - 1}} \Sigma_n^- + \frac{\zeta^{-n+1}}{\sqrt{z^2 - 1}} \Sigma_n^+ + \frac{\zeta - \zeta^{-1}}{\sqrt{z^2 - 1}} \phi_n,
\]

\[
f_{n+1} = \zeta^{n+1} - \frac{\zeta^{n+1}}{\sqrt{z^2 - 1}} \Sigma_n^- + \frac{\zeta^{-n-1}}{\sqrt{z^2 - 1}} \Sigma_n^+.
\]

It follows that

\[
2\sqrt{z^2 - 1}((H_0 - z)f)_n = \sqrt{z^2 - 1} (f_{n-1} + f_{n+1} - 2zf_n) = (\zeta - \zeta^{-1}) \phi_n + (\zeta^{-n+1} + \zeta^{-n-1}) \Sigma_n^+ - (\zeta^{n+1} + \zeta^{n-1}) \Sigma_n^- - 2z(\zeta^{-n} \Sigma_n^+ - \zeta^n \Sigma_n^-). \tag{A.1}
\]

The sums of the terms containing \( \Sigma_n^+ \) and \( \Sigma_n^- \) equal zero because \( \zeta + \zeta^{-1} = 2z \). Since \( \zeta - \zeta^{-1} = -2\sqrt{z^2 - 1} \), equality (A.1) yields the desired equation \(((H_0 - z)f)_n = -(Vf)_n \). \( \Box \)
Next, we study equation (2.11). Let us distinguish the term corresponding to \( m = n + 1 \) in its right-hand side. Then equation (2.11) reads as

\[
2a_nf_n(z) = \zeta(z)^n - 2b_{n+1}f_{n+1}(z) + (1 - 2a_{n+1})f_{n+2}(z) - \frac{1}{\sqrt{z^2 - 1}} \sum_{m=n+2}^{\infty} (\zeta(z)^{n-m} - \zeta(z)^{m-n})(Vf(z))_m.
\]

It is convenient to rewrite this equation in terms of the sequence

\[
g_n(z) = 2a_n\zeta(z)^{-n}f_n(z)
\]

as

\[
g_n(z) = 1 + \sum_{m=n+1}^{\infty} G_{n,m}(z)g_m(z)
\]

where

\[
2a_m\sqrt{z^2 - 1}G_{n,m}(z) = (\zeta(z)^{2m-2n} - 1)b_m + (\zeta(z)^{2m-2n-1} - \zeta(z))(a_{m-1} - 1/2) + (\zeta(z)^{2m-2n+1} - \zeta(z)^{-1})(a_m - 1/2).
\]

It is important that

\[
|G_{n,m}(z)| \leq C\alpha_m
\]

where

\[
\alpha_m = |a_{m-1} - 1/2| + |a_m - 1/2| + |b_m|
\]

and the constant \( C = C(z) \) does not depend on \( n, m \) and on \( z \) in compact subsets of \( \text{clos} \Pi \) away from the points \( \pm 1 \).

Let us solve equation (A.3) by iterations. Put \( g_n^{(0)} = 1 \) for all \( n \in \mathbb{Z}_+ \) and

\[
g_n^{(k+1)}(z) = \sum_{m=n+1}^{\infty} G_{n,m}(z)g_m^{(k)}(z), \quad k \geq 0.
\]

**Lemma A.2.** The estimates

\[
|g_n^{(k)}(z)| \leq \frac{C^k}{k!} \left( \sum_{m=n+1}^{\infty} \alpha_m \right)^k, \quad \forall n \in \mathbb{Z}_+,
\]

are true for all \( k \in \mathbb{Z}_+ \).

**Proof.** Suppose that (A.7) is satisfied for some \( k \in \mathbb{Z}_+ \). We have to check that the same estimate (with \( k \) replaced by \( k + 1 \) in the right-hand side) holds for \( g_n^{(k+1)}(z) \). It follows from (A.5) and (A.7) that

\[
|g_n^{(k+1)}(z)| \leq \frac{C^{k+1}}{k!} \sum_{m=n+1}^{\infty} \alpha_m \left( \sum_{p=m+1}^{\infty} \alpha_p \right)^k.
\]
Observe that
\[(k+1)\alpha_m \left( \sum_{p=m+1}^{\infty} \alpha_p \right)^k + \left( \sum_{p=m+1}^{\infty} \alpha_p \right)^{k+1} \leq \left( \sum_{p=m}^{\infty} \alpha_p \right)^{k+1},\]
and hence, for all \(N \in \mathbb{Z}_+\),
\[(k+1) \sum_{m=n+1}^{N} \alpha_m \left( \sum_{p=m+1}^{\infty} \alpha_p \right)^k \leq \sum_{m=n+1}^{N} \left( \left( \sum_{p=m}^{\infty} \alpha_p \right)^{k+1} - \left( \sum_{p=m+1}^{\infty} \alpha_p \right)^{k+1} \right) \leq \left( \sum_{p=n+1}^{\infty} \alpha_p \right)^{k+1}.

Substituting this estimate into (A.8), we obtain (A.7) for \(g_n^{(k+1)}(z)\).

It is now easy to conclude the proof of Theorem 2.1. Set
\[g_n(z) = \sum_{k=0}^{\infty} g_n^{(k)}(z).\]

Estimate (A.7) shows that this series converges and, by the recurrent definition (A.6), the functions \(g_n(z)\) satisfy equation (A.3) equivalent to (2.11). Since every function \(g_n^{(k)}(z)\) is analytic in \(z \in \Pi\) and is continuous up to the cut \([-1, 1]\) (away from the points \(\pm 1\)), estimate (A.7) guarantees that \(g_n(z)\) and hence \(f_n(z)\) possess the same properties.

It also follows from (A.3) and (A.5) that
\[|g_n(z) - 1| \leq C \sum_{m=n+1}^{\infty} \alpha_m\]
which in view of (A.2) implies (2.13).

As far as Theorem 2.3 is concerned, we note that all functions \(g_n^{(k)}(z)\) are continuous with respect to the cut-off parameter \(N \to \infty\), and therefore estimates obtained in the proof of Theorem 2.1 imply relation (2.16).

**A.2.** Next, we discuss Theorem 3.1. The first assertion is quite similar to Lemma A.1, and so its proof will be omitted.

**Lemma A.3.** Let \(P(z) = \{P_n(z)\}_{n=-1}^{\infty}\) where \(P_{-1}(z) = 0, P_0(z) = 1\) satisfy equations (3.2). Then \(P_n(z)\) satisfy also equations (1.2); in particular, \(P_n(z)\) is a polynomial of degree \(n\).

We proceed from equation (3.2) and, following the scheme of the previous subsection, distinguish the term corresponding to \(m = n - 1\) in the sum (3.2). Then equation (3.2)
reads as

\[ 2a_{n-1} P_n(z) = P_n^{(0)}(z) - 2a_{n-2} P_{n-2}(z) - 2b_{n-1} P_{n-1}(z) \]

\[ + \frac{1}{\sqrt{z^2 - 1}} \sum_{m=0}^{n-2} (\zeta(z)^{n-m} - \zeta(z)^{m-n})(VP(z))_m, \quad n \geq 2. \]

It is convenient to rewrite this equation in terms of the sequence

\[ Q_n(z) = 2a_{n-1} \zeta(z)^n P_n(z) \]

as

\[ Q_n(z) = Q_n^{(0)}(z) - \sum_{m=0}^{n-1} G_{n,m}(z) Q_m(z). \quad (A.9) \]

Here \( Q_n^{(0)}(z) = \zeta(z)^n P_n^{(0)}(z) \) are bounded uniformly in \( n \) in view of (2.8). The matrix elements \( G_{n,m}(z) \) are quite similar to \( G_{n,m}(z) \) defined by (A.4). It is only important that \( G_{n,m}(z) \) satisfy estimate (A.5).

We again solve equation (A.9) by iterations. Put \( Q_n^{(k)}(z) = 0 \) for \( k \geq 1 \) and

\[ Q_n^{(k+1)}(z) = \sum_{m=0}^{n-1} G_{n,m}(z) Q_m^{(k)}(z), \quad k \geq 0, \quad n \geq 1. \quad (A.10) \]

Lemma A.4. The estimates

\[ |Q_n^{(k)}(z)| \leq \frac{C^k}{k!} \left( \sum_{m=0}^{n-1} \alpha_m \right)^k, \quad \forall n \geq 1, \quad (A.11) \]

are true for all \( k \in \mathbb{Z}_+ \).

Proof. Suppose that (A.11) is satisfied for some \( k \in \mathbb{Z}_+ \). We have to check that the same estimate (with \( k \) replaced by \( k+1 \) in the right-hand side) holds for \( Q_n^{(k+1)}(z) \). It follows from (A.10), (A.11) that

\[ |Q_n^{(k+1)}(z)| \leq \frac{C^{k+1}}{k!} \sum_{m=0}^{n-1} \alpha_m \left( \sum_{p=0}^{m-1} \alpha_p \right)^k. \quad (A.12) \]

Observe that

\[ (k+1) \alpha_m \left( \sum_{p=0}^{m-1} \alpha_p \right)^k + \left( \sum_{p=0}^{m-1} \alpha_p \right)^{k+1} \leq \left( \sum_{p=0}^{m} \alpha_p \right)^{k+1}, \]

and hence

\[ (k+1) \sum_{m=0}^{n-1} \alpha_m \left( \sum_{p=0}^{m-1} \alpha_p \right)^k \leq \sum_{m=0}^{n-1} \left( \sum_{p=0}^{m} \alpha_p \right)^{k+1} - \left( \sum_{p=0}^{m-1} \alpha_p \right)^{k+1} \leq \left( \sum_{p=0}^{n-1} \alpha_p \right)^{k+1}. \]

Substituting this estimate into (A.12), we obtain (A.11) for \( k+1 \). \( \square \)
Let us now set
\[ Q_n(z) = \sum_{k=0}^{\infty} Q_n^{(k)}(z). \]

Estimate (A.11) shows that this series converges and
\[ Q_n(z) \leq \sum_{k=0}^{\infty} \frac{C^k}{k!} \left( \sum_{m=0}^{n-1} \alpha_m \right)^k = \exp \left( C \sum_{m=0}^{n-1} \alpha_m \right). \]

By the recurrent definition (A.10), the functions \( Q_n(z) \) satisfy equation (A.9) equivalent to (3.2). This proves estimate (3.1).

**A.3.** The proof of Theorem 4.1 can be obtained similarly to that of Theorem 2.1 if one observes that
\[ \left| \frac{\zeta^{2k} - 1}{\sqrt{\zeta^2 - 1}} \right| = 2 \left| \frac{\zeta^{2k} - 1}{\zeta^2 - 1} \right| = 2|\zeta| |\zeta^2|^{(k-1)} + \zeta^{2(k-2)} + \cdots + \zeta^2 + 1| \leq 2k. \] (A.13)

Thus instead of (A.5), we now have a bound
\[ |G_{n,m}(z)| \leq C(m + 1)\alpha_m \] (A.14)
with a constant \( C \) not depending on \( \zeta \) in the unit disc. Under assumption (4.1) this bound allows us to repeat the arguments of Theorem 2.1.

The proof of Theorem 4.2 follows the scheme of proof of Theorem 3.1, but now we again have to use estimate (A.13). This estimate implies that the kernels \( G_{n,m}(z) \) in (A.9) obey bound (A.14).
