Commutators of singular integrals revisited

Andrei K. Lerner, Sheldy Ombrosi and Israel P. Rivera-Ríos

Abstract
We obtain a Bloom-type characterization of the two-weighted boundedness of iterated commutators of singular integrals. The necessity is established for a rather wide class of operators, providing a new result even in the unweighted setting for the first order commutators.

1. Introduction
Given a linear operator $T$ and a locally integrable function $b$, define the commutator $[b, T]$ of $T$ and $b$ by

$$[b, T]f(x) = b(x)T(f)(x) - T(bf)(x).$$

The iterated commutators $T^m_b$, $m \in \mathbb{N}$, are defined inductively by

$$T^m_b f = [b, T^{m-1}_b]f, \quad T^1_b f = [b, T]f.$$

We say that a linear operator $T$ is an $\omega$-Calderón–Zygmund operator on $\mathbb{R}^n$ if $T$ is $L^2$ bounded, and can be represented as

$$Tf(x) = \int_{\mathbb{R}^n} K(x,y)f(y)dy \quad \text{for all } x \not\in \text{supp } f,$$

with kernel $K$ satisfying the size condition $|K(x,y)| \leq C \frac{1}{|x-y|^n}$, $x \neq y$, and the smoothness condition

$$|K(x,y) - K(x',y)| + |K(y,x) - K(y,x')| \leq \omega\left(\frac{|x-x'|}{|x-y|}\right) \frac{1}{|x-y|^p}$$

for $|x-y| > 2|x-x'|$, where $\omega : [0,1] \rightarrow [0,\infty)$ is continuous, increasing, subadditive and $\omega(0) = 0$. We say that $\omega$ satisfies the Dini condition if $\int_0^1 \omega(t)\frac{dt}{t} < \infty$.

In this paper, we will prove the following result.

Theorem 1.1. Let $\mu, \lambda \in A_p$, $1 < p < \infty$. Further, let $\nu = (\frac{p}{\lambda})^{\frac{1}{p}}$ and $m \in \mathbb{N}$.

(i) If $b \in BMO_{\nu^{1/m}}$, then for every $\omega$-Calderón–Zygmund operator $T$ on $\mathbb{R}^n$ with $\omega$ satisfying the Dini condition,

$$\|T^m_b f\|_{L^p(\lambda)} \leq C_{n,m,T} \|b\|^m_{BMO_{\nu^{1/m}}} \left(\|\nu\|_{A_p}\|\nu\|_{A_p}\right)^{\frac{m+1}{p+m}} \max\left\{1,\frac{1}{\nu}\right\} \|f\|_{L^p(\mu)}.$$

(ii) Let $T_{\Omega}$ be an operator defined by (1.1) with $K(x,y) = \Omega\left(\frac{x-y}{|x-y|}\right)\frac{1}{|x-y|^n}$, where $\Omega$ is a measurable function on $S^{n-1}$, which does not change sign and is not equivalent to zero on...
some open subset from $S^{n-1}$. If there is $c > 0$ such that for every bounded measurable set $E \subset \mathbb{R}^n$,

$$
\|(T_\Omega)_{b,n}(\chi_E)\|_{L^p(\lambda)} \leq c\mu(E)^{1/p},
$$

then $b \in BMO_{p,1/m}$.

**Remark 1.2.** We emphasize that in part (ii) of Theorem 1.1, no size and regularity assumptions on $\Omega$ are imposed. It will be useful, however, to distinguish a class of operators satisfying both parts of the theorem. Assume that

$$
(T_\Omega)f(x) = \text{p.v.} \int_{\mathbb{R}^n} f(x-y) \frac{\Omega(y/|y|)}{|y|^n} dy,
$$

where $\Omega$ is continuous on $S^{n-1}$, not identically zero and $\int_{S^{n-1}} \Omega \, d\sigma = 0$. Assuming additionally that

$$
\omega(\delta) = \sup_{|\theta - \theta'| \leq \delta} |\Omega(\theta) - \Omega(\theta')|
$$

satisfies the Dini condition, we obtain that $T_\Omega$ satisfies both parts of Theorem 1.1.

Recall that $b \in BMO_\eta$ (for a given weight $\eta$) if

$$
||b||_{BMO_\eta} = \sup_Q \frac{1}{\eta(Q)} \int_Q |b(x) - b_Q| \, dx < \infty,
$$

where the supremum is taken over all cubes $Q \subset \mathbb{R}^n$. Here we use the standard notations $\eta(Q) = \int_Q \eta$ and $b_Q = \frac{1}{|Q|} \int_Q b$. We also recall that $w \in A_p, 1 < p < \infty$, if

$$
[w]_{A_p} = \sup_{Q \subset \mathbb{R}^n} \left( \frac{1}{|Q|} \int_Q w \right) \left( \frac{1}{|Q|} \int_Q w^{-1/p'} \right)^{p-1} < \infty.
$$

In what follows, we present a brief history preceding Theorem 1.1, and, in parallel, we outline our novel points.

- Assume first that $m = 1$ and $\lambda = \mu \equiv 1$. In this case Theorem 1.1 was obtained in the celebrated work by Coifman, Rochberg and Weiss [4].

The necessity of $BMO$, expressed in part (ii), was obtained in [4] under the assumption that $[b, R_j]$ is bounded on $L^p$ for every Riesz transform $R_j$. Later this assumption was relaxed in the works by Janson [16] and Uchiyama [21]. It was shown there that the boundedness of $[b, T_\Omega]$ on $L^p$ (where $T_\Omega$ is defined as in Remark 1.2 with $\Omega \in C^\infty(S^{n-1})$ in [16] and $\Omega$ is Lipschitz continuous in [21]) implies $b \in BMO$.

Our novel points in part (ii) (even in the unweighted case and when $m = 1$) are a much wider class of operators (which includes, for instance, a class of rough singular integrals) and the fact that the restricted strong type $(p, p)$ of $[b, T_\Omega]$ (instead of the usual strong type $(p, p)$ in [4, 16, 21]) implies $b \in BMO$.

- Assume that $m = 1$ and $\lambda, \mu \in A_p$. In the one-dimensional case this result was obtained by Bloom [2]. Recently it was extended to higher dimensions by Holmes, Lacey and Wick [10]. Later, a quantitative form of this statement, expressed in estimate (1.2), was obtained by the authors in [19].

As in the unweighted case, part (ii) is new in such generality. In [10] this part was obtained, similar to [4], assuming that $[b, R_j]$ is bounded from $L^p(\mu)$ to $L^p(\lambda)$ for every Riesz transform $R_j$.

- Assume that $m \geq 2$. Suppose now that $\lambda, \mu \in A_p$. In the early 1990s, García-Cuerva, Harboure, Segovia and Torrea [7] proved for a class of strongly singular integrals $S$ that
$b \in BMO_{\nu, \lambda/m}$ implies $S_b^m : L^p(\mu) \to L^p(\lambda)$. It was pointed out in [7] that similar methods can be used to obtain the corresponding estimates for Calderón–Zygmund operators.

Estimate (1.2) represents a quantitative version of that statement. It looks like a natural extension of the case $m = 1$ obtained in [19]. Note, however, that it does not seem that this estimate can be deduced via a simple inductive argument. Observe also that in the case of equal weights, (1.2) recovers the sharp dependence on the $A_p$ constant established by Chung, Pereyra and P´erez [3] for every $m \geq 1$. This indicates that the exponent $(m + 1)/2$ in (1.2) cannot be improved.

Recently, Holmes and Wick [11] obtained the $L^p(\mu) \to L^p(\lambda)$ boundedness of $T_m^b$ under the different assumption $b \in BMO \cap BMO_{\nu}$ with $\nu = (\mu \lambda)^{1/p}$. Hytönen [13] provided a simpler argument for this result based on the conjugation method. We will show below (see Remark 4.7 in Section 4) that the assumption $b \in BMO_{\nu, \lambda/m}$ is less restrictive than $b \in BMO \cap BMO_{\nu}$.

Part (ii) of Theorem 1.1 for $m \geq 2$ is new even for the commutators of the Hilbert transform. Note that in [7] the necessity of $b \in BMO_{\nu, \lambda/m}$ was deduced from the $L^p(\mu) \to L^p(\lambda)$ boundedness of the commutators of the Hardy–Littlewood maximal operator.

Summarizing, our new contribution in Theorem 1.1 is the following.

- If $m \geq 2$, then both parts of Theorem 1.1 are new.
- If $m = 1$, then part (ii) provides a much wider class of operators comparing to the previous works, both in weighted and unweighted cases.
- In part (ii), the necessity of $BMO_{\nu, \lambda/m}$ follows from the weighted restricted strong type $(p,p)$ estimates.

The rest of the paper is organized as follows. Section 2 is devoted to present some needed preliminary results. In Section 3 we prove Theorem 1.1. The last section contains some further comments and remarks related to Theorem 1.1.

2. Preliminaries

2.1. $A_\infty$ weights

Define the $A_\infty$ class of weights by $A_\infty = \cup_{p>1} A_p$. We mention several well-known properties of $A_\infty$ weights (see, for example, [8, Chapter 9]). First, if $w \in A_\infty$, then $w$ is doubling, that is, for every $\lambda > 1$, there is $c > 0$ such that for all cubes $Q$,

$$w(\lambda Q) \leq cw(Q),$$

(2.1)

where $\lambda Q$ denotes the cube with the same center as $Q$ and side length $\lambda$ times that of $Q$. Second, for every $0 < \alpha < 1$, there exists $0 < \beta < 1$ such that for every cube $Q$ and every measurable set $E \subset Q$ with $|E| \geq \alpha |Q|$ one has

$$w(E) \geq \beta w(Q).$$

(2.2)

Next, there exists $\gamma > 0$ such that for every cube $Q$,

$$|\{x \in Q : w(x) \geq \gamma w_Q\}| \geq \frac{1}{2} |Q|.$$

In particular, this property implies immediately that for every cube $Q$ and for all $0 < \delta < 1$,

$$\frac{1}{|Q|} \int_Q w \leq \frac{2^{1/\delta}}{\gamma} \left( \frac{1}{|Q|} \int_Q w^{\delta} \right)^{1/\delta}.$$

(2.3)
2.2. Sparse families and mean oscillations

Given a cube $Q_0 \subset \mathbb{R}^n$, let $\mathcal{D}(Q_0)$ denote the set of all dyadic cubes with respect to $Q_0$, that is, the cubes obtained by repeated subdivision of $Q_0$ and each of its descendants into $2^n$ congruent subcubes.

A dyadic lattice $\mathcal{D}$ in $\mathbb{R}^n$ is any collection of cubes such that

(i) if $Q \in \mathcal{D}$, then each child of $Q$ is in $\mathcal{D}$ as well;

(ii) every 2 cubes $Q', Q'' \in \mathcal{D}$ have a common ancestor, that is, there exists $Q \in \mathcal{D}$ such that $Q', Q'' \in \mathcal{D}(Q)$;

(iii) for every compact set $K \subset \mathbb{R}^n$, there exists a cube $Q \in \mathcal{D}$ containing $K$.

A family of cubes $\mathcal{S}$ is called sparse if there exists $0 < \alpha < 1$ such that for every $Q \in \mathcal{S}$ one can find a measurable set $E_Q \subset Q$ with $|E_Q| \geq \alpha |Q|$, and the sets $\{E_Q\}_{Q \in \mathcal{S}}$ are pairwise disjoint.

Given a measurable function $f$ on $\mathbb{R}^n$ and a cube $Q$, the local mean oscillation of $f$ on $Q$ is defined by

$$\omega_\lambda(f; Q) = \inf_{c \in \mathbb{R}} ((f - c) \chi_Q)^* (\lambda |Q|) \quad (0 < \lambda < 1),$$

where $f^*$ denotes the non-increasing rearrangement of $f$.

By a median value of $f$ over a measurable set $E$ of positive finite measure we mean a possibly non-unique, real number $m_f(E)$ such that

$$\max (|\{x \in E : f(x) > m_f(E)\}|, |\{x \in E : f(x) < m_f(E)\}|) \leq |E|/2.$$

Note that, by Chebyshev’s inequality,

$$\sup_Q \omega_\lambda(f; Q) \frac{|Q|}{\eta(Q)} \leq \frac{1}{\lambda} \|f\|_{BMO} \quad (0 < \lambda < 1). \tag{2.4}$$

By a well-known result due to John [17] and Strömberg [20], the converse estimate holds as well for $\lambda \leq \frac{1}{2}$, thus providing an alternative characterization of $BMO$ in terms of local mean oscillations.

Similar to (2.4), for every weight $\eta$,

$$\sup_Q \omega_\lambda(f; Q) \frac{|Q|}{\eta(Q)} \leq \frac{1}{\lambda} \|f\|_{BMO, \eta} \quad (0 < \lambda < 1).$$

We will show that assuming $\eta \in A_\infty$, the full analogue of the John–Strömberg result holds for $\lambda \leq \lambda_n$. This fact is a simple application of the following result due to the first author [18] and stated below in the refined form obtained by Hytönen [12]: for every measurable function $f$ on a cube $Q$, there exists a (possibly empty) $\frac{1}{2}$-sparse family $\mathcal{S}$ of cubes from $\mathcal{D}(Q)$ such that for a.e. $x \in Q$,

$$|f(x) - m_f(Q)| \leq 2 \sum_{P \in \mathcal{S}} \omega_{\frac{1}{2^{n+2}}} (f; P) \chi_P(x). \tag{2.5}$$

**Lemma 2.1.** Let $\eta \in A_\infty$. Then

$$\|f\|_{BMO, \eta} \leq c \sup_Q \omega_\lambda(f; Q) \frac{|Q|}{\eta(Q)} \left( 0 < \lambda \leq \frac{1}{2^{n+2}} \right), \tag{2.6}$$

where $c$ depends only on $\eta$. 

Proof. Since $\omega_{\lambda}(f; Q)$ is non-increasing in $\lambda$, it sufficed to prove (2.6) for $\lambda = \frac{1}{2m+2}$. Let $Q$ be an arbitrary cube. Then, by (2.5),

$$
\int_Q |f - f_Q| dx \leq 2 \int_Q |f - m_{f}(Q)| dx \leq 4 \sum_{P \in S, P \subseteq Q} \omega_{\frac{1}{2m+2}}(f; P) |P|
$$

$$
\leq 4 \left( \sup_P \omega_{\frac{1}{2m+2}}(f; P) \frac{|P|}{\eta(P)} \right) \sum_{P \in S, P \subseteq Q} \eta(P).
$$

Using that $S$ is sparse and applying (2.2), we obtain

$$
\sum_{P \in S, P \subseteq Q} \eta(P) \leq c \sum_{P \in S, P \subseteq Q} \eta(E_P) \leq c \eta(Q),
$$

which, along with the previous estimate, completes the proof. \qed

We will also use the following result proved recently in [19, Lemma 5.1] and closely related to (2.5): given a dyadic lattice $D$ and a sparse family $S \subset D$, there exists a sparse family $\tilde{S} \subset D$ containing $S$ and such that if $Q \in \tilde{S}$, then for almost every $x \in Q$,

$$
|f(x) - f_Q| \leq 2^{n+2} \sum_{P \in \tilde{S}, P \subseteq Q} \left( \frac{1}{|P|} \int_P |f - f_P| \right) \chi_P(x).
$$

(2.7)

3. Proof of Theorem 1.1

3.1. Proof of part (i)

We recall that in the case $m = 1$, the proof provided in [19] relied upon the sparse domination result

$$
|[b, T]f(x)| \leq c_{n, T} \sum_{j=1}^{3^n} \sum_{Q \in \mathcal{S}_j} |b(x) - b_Q| \left( \frac{1}{|Q|} \int_Q |f| \right) \chi_Q(x)
$$

$$
+ c_{n, T} \sum_{j=1}^{3^n} \sum_{Q \in \mathcal{S}_j} \left( \frac{1}{|Q|} \int_Q |b - b_Q||f| \right) \chi_Q(x),
$$

(3.1)

combined with (2.7) and the sharp weighted $L^p$ bound for sparse operators.

To settle the case $m \geq 2$, we hinge upon the counterpart for iterated commutators obtained in [15],

$$
|T_{b}^{m} f(x)| \leq c_{n, T} \sum_{j=1}^{3^n} \sum_{k=0}^{m} \binom{m}{k} \sum_{Q \in \mathcal{S}_j} |b(x) - b_Q|^{m-k} \left( \frac{1}{|Q|} \int_Q |b - b_Q|^k |f| \right) \chi_Q(x).
$$

(3.2)

The idea of the proof consists in combining that sparse domination with (2.7). However, in contrast with the case $m = 1$, the sparse terms that arise after applying (2.7) may be raised to a power greater than 1. We will deal with those terms exploiting the dyadic structure of the sparse family via (3.5). Bearing those ideas in mind, the rest of the proof can be carried out taking into account the self-adjointness of sparse operators and the sharp weighted $L^p$ bound that they satisfy.

We begin our argument as follows. Observe that taking into account (3.2) it suffices to provide suitable estimates for

$$
A_{b}^{m, k} f(x) = \sum_{Q \in S} |b(x) - b_Q|^{m-k} \left( \frac{1}{|Q|} \int_Q |b - b_Q|^k |f| \right) \chi_Q(x),
$$

where $S$ is a sparse family from some dyadic lattice $D$. 

We start observing that, by duality,
\[
\|A_b^{m,k}f\|_{L^p(\lambda)} \leq \sup_{g \in L^{p'}(\lambda)} \sum_{Q \in S} \left( \int_Q |g\lambda| |b - b_Q|^{m-k} \right) \frac{1}{|Q|} \int_Q |b - b_Q|^k |f|.
\] (3.3)

By (2.7), there exists a sparse family $\tilde{S} \subset \mathcal{D}$ containing $S$ and such that if $Q \in \tilde{S}$, then for almost every $x \in Q$,
\[
|b(x) - b_Q| \leq 2^{n+2} \sum_{P \in \tilde{S}, P \subset Q} \left( \frac{1}{|P|} \int_P |b - b_P| \right) \chi_P(x).
\]

From this, assuming that $b \in BMO_\eta$, where $\eta$ is a weight to be chosen later, we obtain
\[
|b(x) - b_Q| \leq 2^{n+2} \|b\|_{BMO_\eta} \sum_{P \in \tilde{S}, P \subset Q} \eta_P \chi_P(x).
\]

Hence,
\[
\sum_{Q \in S} \left( \int_Q |g\lambda| |b - b_Q|^{m-k} \right) \frac{1}{|Q|} \int_Q |b - b_Q|^k |f| \leq c \|b\|^m_{BMO_\eta} \sum_{Q \in S} \left( \frac{1}{|Q|} \int_Q |g\lambda| \left( \sum_{P \in \tilde{S}, P \subset Q} \eta_P \chi_P \right)^{m-k} \right)
\times \left( \frac{1}{|Q|} \int_Q \left( \sum_{P \in \tilde{S}, P \subset Q} \eta_P \chi_P \right)^k |f| \right) |Q|.
\] (3.4)

Now we note that since the cubes from $\tilde{S}$ are dyadic, for every $l \in \mathbb{N}$,
\[
\left( \sum_{P \in \tilde{S}, P \subset Q} \eta_P \chi_P \right)^l = \sum_{P_1, P_2, \ldots, P_l \subset Q, P_i \in \tilde{S}} \eta_{P_1} \eta_{P_2} \cdots \eta_{P_l} \chi_{P_1 \cap P_2 \cap \cdots \cap P_l}
\leq l! \sum_{P_1 \subseteq P_{l-1} \subseteq \cdots \subseteq P_l \subseteq Q, P_i \in \tilde{S}} \eta_{P_1} \eta_{P_2} \cdots \eta_{P_l} \chi_{P_i}.
\] (3.5)

Therefore,
\[
\int_Q |h| \left( \sum_{P \in \tilde{S}, P \subset Q} \eta_P \chi_P \right)^l \leq l! \sum_{P_1 \subseteq P_{l-1} \subseteq \cdots \subseteq P_l \subseteq Q, P_i \in \tilde{S}} \eta_{P_1} \eta_{P_2} \cdots \eta_{P_l} |h| |P_1| |P_l|.
\]

Further,
\[
\sum_{P_1 \subseteq P_{l-1} \subseteq \cdots \subseteq P_l \subseteq Q, P_i \in \tilde{S}} \eta_{P_1} \eta_{P_2} \cdots \eta_{P_l} |h| |P_1| |P_l|
= \sum_{P_1 \subseteq P_{l-1} \subseteq \cdots \subseteq P_l \subseteq Q, P_i \in \tilde{S}} \eta_{P_1} \eta_{P_2} \cdots \eta_{P_{l-1}} \sum_{P \subseteq \tilde{P}_{l-1}, \tilde{P}_i \in \tilde{S}} |h| \int_{P_i} \eta_i.
\]
\[
\leq \sum_{P_1 \subseteq P_{l-1} \subseteq \cdots \subseteq P_l \subseteq Q, P_i \in \tilde{S}} \eta_{P_1} \eta_{P_2} \cdots \eta_{P_{l-1}} \int_{P_{l-1}} A_S(|h|) \eta_i.
\]
\[
= \sum_{P_1 \subseteq P_{l-1} \subseteq \cdots \subseteq P_l \subseteq Q, P_i \in \tilde{S}} \eta_{P_1} \eta_{P_2} \cdots \eta_{P_{l-1}} \left( A_{S, \eta} |h| \right)_{P_{l-1}, P_{l-1}} |P_{l-1}|.
\]
Combining the obtained estimates with (3.3) yields
\[
\int_Q |h| \left( \sum_{P \subseteq Q} \eta_P \chi_P \right)^l \lesssim \int_Q A_{S, \eta}^l |h|,
\]
where \( A_{S, \eta}^l \) denotes the operator \( A_{S, \eta} \) iterated \( l \) times. From this we obtain that the right-hand side of 3.4 is controlled by
\[
c \|b\|_{BMO}^m \sum_{Q \subseteq S} \left( \frac{1}{|Q|} \int_Q A_{S, \eta}^k (|f|) \right) \left( \frac{1}{|Q|} \int_Q A_{S, \eta}^{m-k} (|g|) \right) |Q|
= c \|b\|_{BMO}^m \int_{\mathbb{R}^n} A_S \left( A_{S, \eta}^k (|f|) \right) A_{S, \eta}^{m-k} (|g|).
\]

Using that the operator \( A_S \) is self-adjoint, we proceed as follows:
\[
\int_{\mathbb{R}^n} A_S \left( A_{S, \eta}^k (|f|) \right) A_{S, \eta}^{m-k} (|g|) = \int_{\mathbb{R}^n} A_S \left( A_{S, \eta}^k (|f|) \right) A_S \left( A_{S, \eta}^{m-k-1} (|g|) \right) \eta
= \int_{\mathbb{R}^n} A_S \left( A_S (|f|) \right) A_{S, \eta}^{m-k-1} (|g|) = \int_{\mathbb{R}^n} A_S \left( A_{S, \eta}^{k+1} (|f|) \right) A_{S, \eta}^{m-k-1} (|g|)
= \cdots = \int_{\mathbb{R}^n} A_S \left( A_{S, \eta}^m (|f|) \right) |g| \lambda.
\]

Combining the obtained estimates with (3.3) yields
\[
\|A_{S, \eta}^m f\|_{L^p(\lambda)} \lesssim \|b\|_{BMO}^m \|A_S (A_{S, \eta}^m (|f|))\|_{L^p(\lambda)}.
\]

Applying that \( \|A_S\|_{L^p(w)} \lesssim \|w\|_{A_p} \max \{1, \frac{1}{p} \} \) (see, for example, [5]), we obtain
\[
\|A_S (A_{S, \eta}^m (|f|))\|_{L^p(\lambda)} \lesssim \|w\|_{A_p} \max \{1, \frac{1}{p} \} \|A_{S, \eta}^m (|f|)\|_{L^p(\lambda)}
= \|w\|_{A_p} \max \{1, \frac{1}{p} \} \|A_{S, \eta}^{m-1} (|f|)\|_{L^p(\lambda)\eta^p}
\lesssim (\|w\|_{A_p} \max \{1, \frac{1}{p} \}) \|A_{S, \eta}^{m-1} (|f|)\|_{L^p(\lambda)\eta^p}
\lesssim (\|w\|_{A_p} \max \{1, \frac{1}{p} \}) \|A_{S, \eta}^{m-1} (|f|)\|_{L^p(\lambda)\eta^p}.
\]

Hence, setting \( \eta = \nu^{1/m} \), where \( \nu = (\mu / \lambda)^{1/p} \) and applying (3.6), we obtain
\[
\|A_{S, \eta}^{m-k} f\|_{L^p(\lambda)} \lesssim \|b\|_{BMO}^m \left( \|w\|_{A_p} \max \{1, \frac{1}{p} \} \right)^{\max \{1, \frac{1}{p} \}} \|f\|_{L^p(\mu)}.
\]

By H"older's inequality,
\[
\prod_{i=1}^{m-1} [\lambda^{1-} \mu^{\nu}]_{A_p} \leq \prod_{i=1}^{m-1} [\lambda^{1-} \mu^{\nu}]_{A_p} = ([\lambda]_{A_p} [\mu]_{A_p})^{\max \{1, \frac{1}{p} \}},
\]
which, along with the previous estimate, yields
\[
\|A_{S, \eta}^{m-k} f\|_{L^p(\lambda)} \lesssim \|b\|_{BMO}^m \left( ([\lambda]_{A_p} [\mu]_{A_p})^{\max \{1, \frac{1}{p} \}} \right) \|f\|_{L^p(\mu)},
\]
and therefore the proof of part (i) is complete.
3.2. Proof of part (ii)

Since \( \mu, \lambda \in A_p \), by Hölder’s inequality, it follows that \( \nu^{1/m} \in A_2 \). Therefore, by Lemma 2.1, it suffices to show that there exists \( c > 0 \) such that for all \( Q \),

\[
\omega_{\frac{1}{2^{n+2}}} (b; Q) \leq c (\nu^{1/m})_Q.
\]

The proof of (3.7) is based on the following auxiliary statement.

**Proposition 3.1.** There exist \( 0 < \varepsilon_0, \xi_0 < 1 \) and \( k_0 > 1 \) depending only on \( \Omega \) and \( n \) such that the following holds. For every cube \( Q \subset \mathbb{R}^n \), there exist measurable sets \( E \subset Q, F \subset k_0 Q \) and \( G \subset E \times F \) with \( |G| \geq \xi_0 |Q|^2 \) such that

1. \( \omega_{\frac{1}{2^{n+2}}} (b; Q) \leq |b(x) - b(y)| \) for all \( (x, y) \in E \times F \);
2. \( \Omega(\frac{x-y}{|x-y|}) \) and \( b(x) - b(y) \) do not change sign in \( E \times F \);
3. \( \Omega(\frac{x-y}{|x-y|}) \geq \varepsilon_0 \) for all \( (x, y) \in G \).

Let us show first how to prove (3.7) using this proposition. Combining properties (i) and (iii) yields

\[
\omega_{\frac{1}{2^{n+2}}} (b; Q)^m |G| \leq \frac{1}{\varepsilon_0} \int_G |b(x) - b(y)|^m \Omega \left( \frac{x-y}{|x-y|} \right) \, dx \, dy.
\]

From this, and using also that \( |x-y| \leq \frac{k_0+1}{2} \text{diam} \, Q \) for all \( (x, y) \in G \), we obtain

\[
\omega_{\frac{1}{2^{n+2}}} (b; Q)^m |G| \leq \frac{1}{\varepsilon_0} \left( \frac{k_0+1}{2} \sqrt{n} \right)^n |Q| \int_G |b(x) - b(y)|^m \Omega \left( \frac{x-y}{|x-y|} \right) \, dx \, dy.
\]

By property (ii), \( (b(x) - b(y))^m \Omega(\frac{x-y}{|x-y|}) \) does not change sign in \( E \times F \). Hence, taking also into account that \( |G| \geq \xi_0 |Q|^2 \), we obtain

\[
\omega_{\frac{1}{2^{n+2}}} (b; Q)^m \leq \frac{1}{\varepsilon_0 \xi_0} \left( \frac{k_0+1}{2} \sqrt{n} \right)^n \frac{1}{|Q|} \int_F |b(x) - b(y)|^m \Omega \left( \frac{x-y}{|x-y|} \right) \, dy \, dx.
\]

Observing that \( (T_\Omega)_b^m \) is represented as

\[
(T_\Omega)_b^m f(x) = \int_{\mathbb{R}^n} (b(x) - b(y))^m \Omega \left( \frac{x-y}{|x-y|} \right) f(y) \, dy \frac{dy}{|x-y|^n} \quad (x \not\in \text{supp} \, f),
\]

the latter estimate can be written as

\[
\omega_{\frac{1}{2^{n+2}}} (b; Q)^m \leq \frac{c}{|Q|} \int_E |(T_\Omega)_b^m (\chi_F)| \, dx,
\]

where \( c \) depends only on \( \Omega \) and \( n \).

By Hölder’s inequality,

\[
\frac{1}{|Q|} \int_E |(T_\Omega)_b^m (\chi_F)| \, dx \leq \frac{1}{|Q|} \left( \int_E |(T_\Omega)_b^m (\chi_F)|^p \, dx \right)^{1/p} \left( \int_Q \lambda^{-\frac{n-1}{p'}} \right)^{1/p'}.
\]

Using the main assumption on \( T_\Omega \) along with the facts that \( F \subset k_0 Q \) and \( \mu \in A_p \) and taking into account (2.1), we obtain

\[
\left( \int_E |(T_\Omega)_b^m (\chi_F)|^p \, dx \right)^{1/p} \leq c \mu(F)^{1/p} \leq c \mu(Q)^{1/p},
\]
which, along with the previous estimate and (3.8), implies
\[
\omega_{1/2^{n+2}}(b; Q)^m \leq c \left( \frac{1}{|Q|} \int_Q \mu^{1/m} \right) \left( \frac{1}{|Q|} \int_Q \lambda^{-\frac{1}{r'}} \right)^{1/p'}. 
\]

By (2.3), \( \frac{1}{|Q|} \int_Q \mu \leq c(\frac{1}{|Q|} \int_Q \mu^{1/r})^r \) for \( r > 1 \). Further, by Hölder’s inequality,
\[
\left( \frac{1}{|Q|} \int_Q \mu^{1/r} \right)^r \leq \left( \frac{1}{|Q|} \int_Q \nu^{1/m} \right)^{mp} \left( \frac{1}{|Q|} \int_I \lambda^{-\frac{1}{mp}} \right)^{r - mp}.
\]

Therefore, taking \( r = mp + 1 \), we obtain
\[
\omega_{1/2^{n+2}}(b; Q)^m \leq c \left( \frac{1}{|Q|} \int_Q \nu^{1/m} \right)^m \left( \frac{1}{|Q|} \int_Q \lambda^{1/p} \right)^{1/p'} \left( \frac{1}{|Q|} \int_I \lambda^{-\frac{1}{r'}} \right)^{1/p'} 
\leq c \left( \frac{1}{|Q|} \int_Q \nu^{1/m} \right)^m,
\]
which proves (3.7).

**Proof of Proposition 3.1.** Let \( \Sigma \subset S^{n-1} \) be an open set such that \( \Omega \) does not change sign and not equivalent to zero there. Then there exists a point \( \theta_0 \in \Sigma \) of approximate continuity (see, for example, [6, p. 46] for this notion) of \( \Omega \) and such that \( |\Omega(\theta_0)| = 2\epsilon_0 \) for some \( \epsilon_0 > 0 \). By the definition of approximate continuity, for every \( \varepsilon > 0 \),
\[
\lim_{\delta \to 0} \frac{\sigma\{\theta \in B(\theta_0, \delta) \cap S^{n-1} : |\Omega(\theta) - \Omega(\theta_0)| < \varepsilon\}}{\sigma(B(\theta_0, \delta) \cap S^{n-1})} = 1,
\]
where \( B(\theta_0, \delta) \) denotes the open ball centered at \( \theta_0 \) of radius \( \delta \), and \( \sigma \) denotes the surface measure on \( S^{n-1} \). Therefore, for every \( 0 < \alpha < 1 \), one can find \( \delta_\alpha > 0 \) such that
\[
B(\theta_0, \delta_\alpha) \cap S^{n-1} \subset \Sigma
\]
and
\[
\sigma\{\theta \in B(\theta_0, \delta_\alpha) \cap S^{n-1} : |\Omega(\theta)| \geq \varepsilon_0\} \geq (1 - \alpha)\sigma\{B(\theta_0, \delta_\alpha) \cap S^{n-1}\}.
\]

(3.9)

Let \( Q \subset \mathbb{R}^n \) be an arbitrary cube. Take the smallest \( r > 0 \) such that \( Q \subset B(x_0, r) \). Let \( \theta \in B(\theta_0, \delta_\alpha/2) \cap S^{n-1} \) and let \( y = x_0 + R\theta \), where \( R > 0 \) will be chosen later. Our goal is to choose \( R \) such that the estimate \( \|\frac{x-y}{|x-y|} - \theta_0\| < \delta_\alpha \) will hold for all \( x \in B(x_0, r) \).

Write \( x \in B(x_0, r) \) as \( x = x_0 + \gamma \nu \), where \( \nu \in S^{n-1} \) and \( 0 < \gamma < r \). We have
\[
\frac{x - y}{|x - y|} = \theta + \frac{\gamma \nu - (R - |x - y|)\theta}{|x - y|}. 
\]

Further,
\[
\frac{|\gamma \nu - (R - |x - y|)\theta|}{|x - y|} \leq \frac{\gamma}{|x - y|} + \frac{|R - |x - y||}{|x - y|} 
\leq \frac{2\gamma}{|x - y|} \leq \frac{2\gamma}{R - \gamma} \leq \frac{2r}{R - r}.
\]

For every \( R \geq \frac{(4 + \delta_\alpha)r}{\delta_\alpha} \) we have \( \frac{2r}{R - r} \leq \frac{\delta_\alpha}{2} \) and therefore,
\[
\left| \frac{x - y}{|x - y|} - \theta_0 \right| \leq |\theta - \theta_0| + \frac{2r}{R - r} < \delta_\alpha.
\]
Hence, setting
\[ \mathcal{F}_\alpha = \left\{ x_0 + R\theta : \theta \in B(\theta_0, \delta_\alpha/2) \cap S^{n-1}, \frac{(4 + \delta_\alpha)r}{\delta_\alpha} \leq R \leq \frac{(4 + \delta_\alpha)2r}{\delta_\alpha} \right\}, \]
we obtain that
\[ \frac{x - y}{|x - y|} \in B(\theta_0, \delta_\alpha) \cap S^{n-1} \subset \Sigma \quad ((x, y) \in Q \times \mathcal{F}_\alpha). \tag{3.10} \]
Also, it follows easily from the definition of \( \mathcal{F}_\alpha \) that
\[ \mathcal{F}_\alpha \subset k(\delta_\alpha, n)Q \quad \text{and} \quad |\mathcal{F}_\alpha| \geq \rho_n \frac{|Q|}{\delta_\alpha}. \tag{3.11} \]
By (3.10), \( \Omega(\frac{x - y}{|x - y|}) \) does not change sign on \( Q \times \mathcal{F}_\alpha \). Let us show now that choosing \( \alpha \) small enough, we obtain that \( |\Omega(\frac{x - y}{|x - y|})| < \varepsilon_0 \) on a small subset of \( Q \times \mathcal{F}_\alpha \). Set
\[ N = \{ \theta \in B(\theta_0, \delta_\alpha) \cap S^{n-1} : |\Omega(\theta)| < \varepsilon_0 \} \]
and
\[ \mathcal{G}_\alpha = \left\{ (x, y) \in Q \times \mathcal{F}_\alpha : \frac{x - y}{|x - y|} \in N \right\}. \]
Let us estimate \( |\mathcal{G}_\alpha| \). For \( x \in Q \) denote
\[ \mathcal{G}_\alpha(x) = \left\{ y \in \mathcal{F}_\alpha : \frac{x - y}{|x - y|} \in N \right\}. \]
Note that by (3.9),
\[ \sigma(N) \leq c_n \alpha \sigma(B(\theta_0, \delta_\alpha) \cap S^{n-1}) \leq c_n \alpha \delta_\alpha^n. \]
Next, for all \((x, y) \in Q \times \mathcal{F}_\alpha\) we have \(|x - y| \leq c' \frac{r}{\delta_\alpha}\), and hence,
\[ |\mathcal{G}_\alpha(x)| \leq \left\{ s \theta : 0 \leq s \leq c' \frac{r}{\delta_\alpha}, \theta \in N \right\} \leq c'' \frac{|Q|}{\delta_\alpha} \sigma(N) \leq \beta_n \alpha |Q| \frac{|Q|}{\delta_\alpha}. \]
Therefore,
\[ |\mathcal{G}_\alpha| = \int_Q |\mathcal{G}_\alpha(x)| dx \leq \beta_n \alpha |Q|^2 \frac{|Q|}{\delta_\alpha}. \]
Combining this with the second part of (3.11), we obtain that there exists \( \alpha_0 < 1 \) depending only on \( n \) such that
\[ |\mathcal{G}_{\alpha_0}| \leq \frac{1}{2^{n+5}} |\mathcal{F}_{\alpha_0}| |Q|. \tag{3.12} \]
By the definition of \( \omega_{1/2^{n+2}}(b; Q) \), there exists a subset \( \mathcal{E} \subset Q \) with \( |\mathcal{E}| = \frac{1}{2^{n+2}} |Q| \) such that for every \( x \in \mathcal{E} \),
\[ \omega_{1/2^{n+2}}(b; Q) \leq |b(x) - m_b(\mathcal{F}_{\alpha_0})|. \tag{3.13} \]
Next, there exist subsets \( E \subset \mathcal{E} \) and \( F \subset \mathcal{F}_{\alpha_0} \) such that \( |E| = \frac{1}{2^{n+2}} |Q| \) and \( |F| = \frac{1}{2} |\mathcal{F}_{\alpha_0}| \), and, moreover,
\[ |b(x) - m_b(\mathcal{F}_{\alpha_0})| \leq |b(x) - b(y)| \tag{3.14} \]
for all \( x \in E, y \in F \) and \( b(x) - b(y) \) does not change sign in \( E \times F \). Indeed, take \( E \) as a subset of either
\[ E_1 = \{ x \in \mathcal{E} : b(x) \geq m_b(\mathcal{F}_{\alpha_0}) \} \quad \text{or} \quad E_2 = \{ x \in \mathcal{E} : b(x) \leq m_b(\mathcal{F}_{\alpha_0}) \}. \]
with $|E_i| \geq \frac{1}{2}|E|$, and the corresponding $F$ will be either $\{y \in \mathcal{F}_\alpha : b(y) \leq m_b(\mathcal{F}_{\alpha_0})\}$ with $|F| = \frac{1}{2}|\mathcal{F}_{\alpha_0}|$ or its complement.

Combining (3.13) and (3.14) yields property (i) of Proposition 3.1. Also, since $\Omega(\frac{x-y}{|x-y|})$ does not change sign on $Q \times \mathcal{F}_{\alpha_0}$, we have that property (ii) holds as well. Next, setting $G = (E \times F) \setminus \mathcal{G}_{\alpha_0}$, we obtain, by the second part of (3.11) and (3.12), that

$$|G| \geq |E||F| - |\mathcal{G}_{\alpha_0}| \geq 1/\nu_0 |Q|^2,$$

where $\nu_0$ depends only on $\Omega$ and $n$, and, moreover, property (iii) follows from the definition of $\mathcal{G}_{\alpha_0}$. Therefore, Proposition 3.1 is completely proved. □

4. Remarks and complements

Remark 4.1. The second part of Theorem 1.1 leaves an interesting question whether the assumption on $\Omega$ that it does not change sign on some open subset from $S_{n-1}$ can be further relaxed. In particular, one can ask whether this part holds for arbitrary measurable function $\Omega$, which is not equivalent to zero.

Remark 4.2. Similar to [4, 10, 21], Theorem 1.1 can be applied to provide a weak factorization result for Hardy spaces. For example, following Holmes, Lacey and Wick [10], one can characterize the weighted Hardy space $H^1(\nu)$ but in terms of a single singular integral, as this was done by Uchiyama [21]. The following proposition can be proved exactly as [10, Corollary 1.4].

Proposition 4.3. Under the hypotheses and notation of Theorem 1.1 and for the class of operators $T_{\Omega}$ described in Remark 1.2, we have that

$$\|f\|_{H^1(\nu)} \simeq \inf \left\{ \sum_{i=1}^{\infty} \|g_i\|_{L^p(\lambda^1)} \|h_i\|_{L^p(\mu)} : f = \sum_{i=1}^{\infty} (g_i(T_{\Omega})h_i - h_i(T_{\Omega})^* g_i) \right\}.$$

Remark 4.4. Comparing both parts of Theorem 1.1, for the class of operators described in Remark 1.2 we have that the $L^p(\mu) \to L^p(\lambda)$ boundedness of $(T_{\Omega})^m_0$ is equivalent to the restricted $L^p(\mu) \to L^p(\lambda)$ boundedness. It is interesting that $BMO_{\nu,1/m}$ does not appear in this statement, though it plays the central role in the proof.

Remark 4.5. Theorem 1.1 answers the following question: what is the relation between the boundedness properties of commutators of different order? Again, let $T_{\Omega}$ be a singular integral as in Remark 1.2. Assume that $w \in A_\mu$. Then Theorem 1.1 implies immediately that for every fixed $k, m \in \mathbb{N}, k \neq m$,

$$(T_{\Omega})^m_0 : L^p(w) \to L^p(w) \iff (T_{\Omega})^k_0 : L^p(w) \to L^p(w).$$

(4.1)

As in the previous remark, this implication is linked by $BMO$.

However, in the case of different weights, an analogue of (4.1) is not true in any direction, as the following example shows.
EXAMPLE 4.6. Let $n = 1$ and let $H$ be the Hilbert transform. Set $\mu = |x|^{1/2}$ and $\lambda = 1$. Then we obviously have that $\mu, \lambda \in A_2$. Define $\nu = (\mu/\lambda)^{1/2} = |x|^{1/4}$ and let $b = \nu^{1/2} = |x|^{1/8}$. Therefore, by Theorem 1.1, $b \in BMO_{\nu^{1/2}}$, since for every interval $I \subset \mathbb{R}$,
\[
\frac{1}{\nu^{1/2}(I)} \int_I |\nu^{1/2} - (\nu^{1/2})_I| dx \leq 2.
\]

Therefore, by Theorem 1.1, $H_b^2 : L^2(\mu) \to L^2$. On the other hand, taking $I_x = (0, \varepsilon)$ with $\varepsilon$ arbitrary small, we obtain
\[
\frac{1}{\nu(I_x)} \int_{I_x} |\nu^{1/2} - (\nu^{1/2})_{I_x}| dx = \frac{5}{4\varepsilon^{5/4}} \int_0^\varepsilon \left| x^{1/8} - \frac{8}{9} \varepsilon^{1/8} \right| dx \geq \frac{c}{\varepsilon^{1/8}}.
\]

Therefore, $b \notin BMO_\nu$ and hence, by Bloom’s theorem, $[b, H] : L^2(\mu) \not\to L^2$.

On the other hand, set $\mu = |x|^{-1/2}$ and $\lambda = 1$. Then again $\mu, \lambda \in A_2$. Define $\nu = (\mu/\lambda)^{1/2} = |x|^{-1/4}$ and let $b = \nu$. Then, arguing exactly as above, we obtain that $b \in BMO_\nu$ (and hence, $[b, H] : L^2(\mu) \to L^2$) and $b \notin BMO_{\nu^{1/2}}$. Therefore, by Theorem 1.1, $H_b^2 : L^2(\mu) \not\to L^2$.

REMARK 4.7. Compare the condition $b \in BMO_{\nu^{1/2}}$ with $b \in BMO \cap BMO_\nu$ from the works [11, 13]. First, as we mentioned before, if $\mu, \lambda \in A_p$, then $\nu = \left(\frac{\mu}{\lambda}\right)^{1/2} \in A_2$.

LEMMA 4.8. Let $u \in A_2$ and $r > 1$. Then
\[
BMO_u \cap BMO \subseteq BMO_{u^{1/r}}. \tag{4.2}
\]

Furthermore, the embedding (4.2) is strict, in general. Namely, for every $r > 1$, there exists a weight $u \in A_2$ and a function $b \in BMO_{u^{1/r}} \setminus BMO$.

Proof. By (2.3),
\[
\frac{1}{u^+(Q)} \int_Q |b(x) - b_Q| dx \leq \frac{c}{u(Q)^{1/2}|Q|^{1/2}} \int_Q |b(x) - b_Q| dx = c \left(\frac{1}{u(Q)} \int_Q |b(x) - b_Q| dx\right)^{1/2} \left(\frac{1}{|Q|} \int_Q |b(x) - b_Q| dx\right)^{1/2},
\]
from which (4.2) readily follows.

To show the second part of the lemma, we use the same idea as in Example 4.6. Let $u(x) = |x|^\alpha$, $0 < \alpha < n$. Then $u \in A_2$. Let $b = u^{1/r} = |x|^\alpha/r$. Then $b \in BMO_{u^{1/r}}$. However, $b \notin BMO$, since it is clear that $b$ does not satisfy the John–Nirenberg inequality. 

Take an integer $m \geq 2$. In accordance with Lemma 4.8, take $u \in A_2$ and $b \in BMO_{u^{1/m}} \setminus BMO$. Then, setting $\mu = u$ and $\lambda = 1$, by Theorem 1.1 we obtain that $T^m_b : L^p(u) \to L^p$ for every $p \geq 2$. This kind of estimates is not covered in [11] due to the fact that $b \notin BMO$.

Very recently we have learned that after finishing this paper some results concerning the necessity of $BMO$ for the endpoint estimate of commutators have been obtained. We remit the interested reader to [1, 9] for those results. In an even more recent work [14], a more general version of the second part of Theorem 1.1 has been obtained, answering positively a question posed in Remark 4.1.
