ABSTRACT

The influence of ripening (12, 18 and 24 months) and in vitro digestion on the peptidomic profile of Parmigiano-Reggiano (PR) cheeses were investigated. Ripening and in vitro digestion thoroughly modified the peptidomic profile of the three cheeses. Twenty-six bioactive peptides were identified in undigested PR. Some peptides were degraded and others released during ripening. After digestion, 52 bioactive peptides were identified. Semi-quantitative data suggested that bioactive peptides released after digestion can be clustered in 5 groups according to the ripening time. VPP and IPP peptide levels in undigested samples were in the range of 4.52-11.34 and 0.66-4.24 mg Kg$^{-1}$, with the highest amounts found in 18-month ripened PR. YPFPGPI peptide was absent in undigested PRs but was released after digestion, especially in the 12-month-old sample (20.18 mg Kg$^{-1}$). The present study suggests possible differences in bioactive peptide levels after digestion as a function of the duration of ripening of PR cheese.
1. Introduction

Cheese ripening is characterized by a complex chain of events that entails an intricate set of biochemical reactions. Among the different biochemical events occurring during cheese ripening, proteolysis is undeniably one of the most important. Several enzymatic activities originating from various sources are involved in the proteolysis process during cheese ripening. Curd and endogenous milk proteolytic enzymes (such as plasmin) initially hydrolyze caseins, generating large or intermediate-size peptides. The released peptides are further cleaved by the action of proteinases and peptidases coming from starter (S-LAB) and nonstarter (NS-LAB) lactic acid bacteria (Sforza et al., 2012).

Bioactive peptides can be defined as short amino acid sequences, originally encrypted within the sequence of the parent protein, which can be released after proteolysis and may have a positive impact on human health (Rizzello et al., 2016). Numerous bioactive peptides have been identified and characterized after hydrolysis of different food proteins or in fermented dairy products, presenting different functional activities including antimicrobial, antioxidative, dipeptidyl peptidase-IV (DPP-IV) and angiotensin-converting enzyme (ACE) inhibition, antihypertensive, immunomodulatory and opioid activities (Nongonierma & FitzGerald, 2015; Rizzello et al., 2016).

In cheese, the presence of bioactive peptides is the result of a sensitive equilibrium between their release and their degradation by the activity of lactic acid bacteria proteinases and peptidases during cheese ripening (Sforza et al., 2004; Sforza et al., 2012). Numerous bioactive peptides, especially ACE-inhibitory and anti-hypertensive peptides, have been identified in various cheeses (Sieber et al., 2010; Lu, Govindasamy-Lucey, & Lucey, 2015; Stuknyte, Cattaneo, Masotti, & De Noni, 2015; Basiricò et al., 2015). Meyer, Bütkofer, Walther, Wechsler, & Sieber (2009) investigated the changes in concentration of the lactotripeptides VPP and IPP in different Swiss cheese varieties during the ripening; they found that the concentration of VPP and IPP increased in semi-hard cheeses according to the ripening time whereas, in hard cheeses, the behavior was dependent on the cheese varieties. Gómez-Ruiz, Ramos, & Recio (2004) and Ong, & Shah (2008) investigated the
release of 5 and 6 ACE-inhibitory peptides during ripening of Manchego and Cheddar cheeses, respectively. In both cases, the authors did not find a general trend for the release of those peptides during cheese ripening.

Parmigiano-Reggiano is a long ripened, hard cheese made from raw cow milk and whey starter as sources of fermenting microorganisms (Solieri, Bianchi, & Giudici, 2012). Parmigiano-Reggiano is characterized by positive nutritional qualities, being an important source of essential nutrients, such as proteins, fat, vitamins and minerals, and is considered a functional food due to the presence of different compounds with particular biological activities (Summer et al., 2017; Godos et al., 2019).

Very few studies have investigated the presence of bioactive peptides and their fate during ripening in Parmigiano-Reggiano. Sforza et al. (2012) gave the most detailed scenario of the evolution of peptides during Parmigiano-Reggiano ripening. Several bioactive peptides were found to be present in Parmigiano-Reggiano, such as the antimicrobial peptide isracidin (αS1-casein fragment 1-23), the multifunctional bioactive peptides YQEPVLGPVRGPFPIIV (β-casein fragment 193-209) and some caseinophosphopeptides (Sforza et al., 2012). Basiricò et al. (2015) identified and quantified 4 anti-hypertensive peptides (VPP, IPP, HLPLP and LHLPLP) in the water-soluble extract of 12-months ripened Parmigiano-Reggiano. However, a detailed picture of the presence and evolution of such bioactive peptides during cheese ripening is still lacking.

In addition, bioactive peptides might be degraded by gastro-intestinal proteases after ingestion. Nevertheless, new sequences could be released from inactive or less active precursors after digestion. Stuknite et al. (2015) identified and quantified 8 ACE-inhibitory peptides in different types of cheeses, which amounts were variably influenced by in vitro gastro-intestinal digestion. In another study, Sánchez-Rivera et al. (2014) investigated the influence of in vitro gastro-intestinal digestion on the peptidomic profile of Spanish blue cheese. They found that some peptides were degraded during cheese digestion, whereas some others were newly released by gastro-intestinal proteases. In this way, at the end of the digestion, a higher number of bioactive peptides were found. Basiricò et al. (2015) studied the fate of 8 anti-hypertensive peptides during in vitro gastro-
intestinal digestion of Parmigiano-Reggiano. The concentration of some peptides such as VPP and IPP was mostly un-affected by the \textit{in vitro} digestion, whereas HLPLP and LHLPLP levels greatly increased after the digestive process. Some other peptides, such as AYFYPE and AYFYPEL, were not found in the Parmigiano-Reggiano samples but they were released during \textit{in vitro} digestion. These results suggest that \textit{in vitro} digestion greatly influences the peptidomic profile of cheese.

The present study was designed to compare the peptidomic profile of Parmigiano-Reggiano cheese at different times of ripening as well as the influence of \textit{in vitro} gastro-intestinal digestion. Bioactive peptides were identified, relatively quantified (by integration of the peak area of individual peptides) and their fate was followed during ripening and \textit{in vitro} digestion. Finally, three well-known bioactive peptides, namely VPP, IPP and YPFPGPI, were quantified in the different samples before and after \textit{in vitro} digestion.

2. Materials and methods

2.1. Materials

All MS/MS reagents were from Bio-Rad (Hercules, CA, U.S.A.), whereas the chemicals and enzymes for the digestion procedure and hydrolysis degree determination were purchased from Sigma-Aldrich (Milan, Italy). Amicon Ultra-4 regenerated cellulose filters with a molecular weight cut-off of 3 kDa were supplied by Millipore (Milan, Italy). Parmigiano-Reggiano cheese samples at 12 (PR12), 18 (PR18) and 24 (PR24) months of ripening were withdrawn from the same cheese factory in the province of Reggio Emilia (Italy). Three different Parmigiano-Reggiano cheese samples for each time-point were analysed; these samples were collected the same day from different batches. Cheese production and ripening were carried out according to the Production Specification regulated by the Safeguarding Consortium. The analysed cheese sample were registered as a Protected Designation of Origin (PDO) cheese. A detailed description of the Parmigiano-Reggiano cheese production and maturation according to the PDO can be found in
Sforza et al. (2012). VPP, IPP and YPFPGPI (95% purity) were synthesized by Bio-Fab research (Rome, Italy). All the other reagents were from Carlo Erba (Milan, Italy).

2.2. Preparation of water-soluble peptides extract (WSPE) from Parmigiano-Reggiano samples

Water-soluble peptides extracts were obtained as described by Sforza et al. (2012) with slight modifications. Five grams of cheese samples were mixed with 45 mL of 0.1 mmol L$^{-1}$ HCl and homogenized for 1 min (3 cycles) using an Ultra-Turrax homogenizer. The samples were then centrifuged at 4000$\times$g for 40 min at 4°C. At the end of the centrifugation, the supernatants were collected and filtered through Whatman filters paper 4 (Maidstone, Kent, UK).

2.3. In vitro gastro-intestinal digestion of Parmigiano-Reggiano samples using the harmonized protocol

The in vitro digestion of Parmigiano-Reggiano samples was carried out by following the protocol previously developed within the COST Action INFOGEST (Minekus et al., 2014). Simulated salivary, gastric and intestinal fluids (SSF, SGF and SIF) were prepared exactly as described by Minekus et al. (2014). Cheese samples (5 g) were mixed with 5 mL of SSF (containing 150 U mL$^{-1}$ of salivary $\alpha$-amylase), ground and incubated for 5 min at 37°C to reproduce mastication. The bolus was then mixed with 10 mL of SGF (containing 4000 U mL$^{-1}$ of porcine pepsin) and the pH adjusted to 2.0 with 6 mol L$^{-1}$ of HCl. After 2 h of incubation at 37°C, the final intestinal step was carried out by adding 20 mL of SIF (containing pancreatin 200 U mL$^{-1}$ based on trypsin activity). Then, the pH was adjusted to 7.0 and the samples were further incubated at 37°C for 2 h. All samples were immediately cooled on ice, centrifuged at 10000 g for 20 min at 4°C and frozen at -80°C for further analysis. The digestions were performed in triplicate. In addition, a control digestion, which included only the gastro-intestinal juices and enzymes, and water in place of cheese, was carried out to consider the possible impact of the digestive enzymes in the subsequent
analysis. For each digestion, aliquots were taken at the end of the gastric and intestinal phases of
digestion.

2.4. Preparation of the peptide fractions and determination of peptides concentration
Low molecular weight peptides from WSPE and digested samples were extracted by ultrafiltration
(cut-off 3 kDa) as described in Tagliazucchi et al. (2017). The peptide content in these peptide
fractions was determined by measuring the amount of released amino groups using the 2,4,6-
trinitrobenzenesulfonic acid (TNBS) assay and leucine as standard (Adler-Nissen, 1979). The
obtained raw data from the digested samples were corrected by the contribution of the control
digestion. Data are expressed as mmol leucine equivalent g⁻¹ of cheese.

2.5. Identification of low molecular weight peptides by ultra high performance liquid
chromatography/high resolution mass spectrometry (UHPLC/HR-MS)
The peptide fractions from WSPE and digested samples were subjected to UHPLC/HR-MS analysis
for peptide identification. UHPLC/MS and tandem MS experiments were carried out on an UHPLC
Ultimate 3000 separation module interfaced with a Q Exactive Hybrid Quadrupole-Orbitrap Mass
Spectrometer (Thermo Scientific, San Jose, CA, USA) using a C18 column (Zorbax SB-C18
reversed-phase, 2.1 × 50 mm, 1.8 μm particle size, Agilent Technologies, Santa Clara, CA, USA).
The mobile phase consisted of (A) H₂O/formic acid (99.9:0.1, v/v) and (B) acetonitrile. The sample
(10 μL, 100-fold diluted) was loaded into the column at a flow rate of 0.3 mL/min. The gradient
started at 2% B, and grew to 3% B in 2 min. The mobile phase composition was raised to 27% B in
19 min and then to 90% in 4 min. The mass spectrometer was set as follow: spray voltage 3.5 kV,
capillary temperature 320°C, sheath gas 40 and auxiliary gas 30. Full MS parameters were:
resolution 70000, AGC target 3e6, maximum IT 333 ms and scan range 200 to 2000 m/z. MS/MS
parameters were: resolution 17500, AGC target 1e5, maximum IT 120 ms and isolation window 3
m/z.
The MS/MS spectra were then converted to .mgf files and the peptides were identified by using the Swiss-Prot database through MASCOT (Matrix Science, Boston, MA, USA) protein identification software. The following parameters were considered: enzyme, none; peptide mass tolerance, ± 5 ppm; fragment mass tolerance, ± 0.12 Da; variable modification, oxidation (M) and phosphorylation (ST); maximal number of post-translational modifications permitted in a single peptide, 4. The assignment process was validated by the manual inspection of MS/MS spectra.

2.6. Identification of bioactive peptides

Peptides identified in the peptide fractions from WSPE and digested samples were investigated in relation to bioactive peptides previously identified in the literature using the Milk Bioactive Peptides Database (MBPDB) (Nielsen, Beverly, Qu, & Dallas, 2017). Only peptides with 100% homology to acknowledged functional peptides were considered as bioactive peptides. The relative amount of the bioactive peptides was estimated by integrating the area under the peak (AUP). AUP was measured from the extracted ion chromatograms (EIC) obtained for each peptide (tolerance ± 5 ppm). Data are expressed as AUP g⁻¹ of cheese.

2.7. Quantification of VPP, IPP and YPFPGPI by parallel reaction monitoring (PRM)

Synthetic peptides were dissolved in solvent A (H₂O/formic acid; 99.9:0.1, v/v) at a concentration of 5 mg mL⁻¹. The selected analytes were quantified by standard addition method spiking known amounts of standard solutions directly to the analyzed samples. For each sample, linear range for VPP and IPP standards were generated by using 0, 4, 8, 16 and 32 µg L⁻¹ of standard (final concentrations in the samples). For YPFPGPI, the linear range was obtained at 0, 5, 15, 30, 50 µg L⁻¹ of standard (final concentrations in the samples).

The samples (10 µL; 100-fold diluted) were then injected in the same UHPLC/HR-MS instrument as describe above. Each sample was analyzed two times. Mobile phase A was 0.1% formic acid in water and mobile phase B was acetonitrile. The elution gradient started with 2% B, was maintained
for 2 min, and then increased to 15% B between 2 and 6 min. The mobile phase composition was then increased to 27% B in 15 min and further raised to 90% B in 4 min. The flow rate was set at 0.4 mL min\(^{-1}\).

Ion source parameters was as follow: spray voltage 4 kV, capillary temperature 320 °C, sheath gas 50 and auxiliary gas 25. PRM parameters were as follow: resolution 17500, AGC target 5e5, max IT 150 ms, MSX count 1 and isolation window 3.0 m/z.

The precursor ions selected for VPP, IPP and YPFPGPI were \([M + H]^+\) \(m/z\) 312.1918, 326.2074 and 790.4134, respectively. The product ion \(y_2^+\) at \(m/z\) 213.1234 was selected for quantitation of VPP and IPP. The product ion \(y_2^+\) at \(m/z\) 229.1547 was selected for quantitation of YPFPGPI.

Peaks were integrated by using the Genesis algorithm function in the Thermo Xcalibur Quantitative Browser, and 5 ppm mass tolerance was applied for the extraction of target product ions. For each sample analyzed, three calibration curves were generated by linear regression analysis and the concentration of each peptide in the sample was calculated by determining the value of the intercept in the x-axis, which represent the initial analyte concentration in the sample.

2.8. Statistical analysis

All data are presented as mean ± standard deviation (SD) for three replicates for each prepared sample. Univariate analysis of variance (ANOVA) with Tukey post-hoc test was applied using GraphPad Prism 6.0 (GraphPad Software, San Diego, CA, USA). The differences were considered significant with \(P <0.05\).
3. Results and discussion

3.1. Total peptides quantification in the peptide fractions of Parmigiano-Reggiano (PR) WSPE and digested samples

During cheese ripening, caseins can be hydrolyzed by the activity of proteases and peptidases mainly derived from S-LAB and NS-LAB (Pangallo et al., 2019). Generally, LAB possess a complex proteolytic system, which is able to hydrolyze milk caseins to short peptides and amino acids to fulfill their amino acid requirements (Tagliazucchi, Martini, & Solieri, 2019). LAB cell-envelope proteases (CEPs) break down caseins into protein fragments (mainly oligopeptides of about 5-30 amino acids) (Solieri, De Vero, & Tagliazucchi, 2018). These peptides can be transported into the cell and further hydrolyzed by cytoplasmic peptidases into smaller peptides and amino acids (Tagliazucchi et al., 2019). As shown in Figure 1, ripening affected the extent of proteolysis in PR samples, as determined by the TNBS assay. The amount of water-soluble low molecular weight peptides did not differ between PR12 and PR18 samples whereas a significant increase was observed in PR24 sample ($P < 0.05$).

Previous studies already confirmed an increase in proteolysis as a function of cheese ripening (Bütikofer, Meyer, Sieber, Walther, & Wechsler, 2008; Stuknite et al., 2015). Gaiaschi et al. (2001) reported that the extent of proteolysis in Grana Padano cheese was high in the first 12 months of ripening, reaching a plateau and further increased after 22 months of ripening.

An increase in the level of low molecular weight peptides was observed for PR cheeses at different ripening time-points after gastric digestion (Figure 1). The amount of peptides released from PR24 after gastric digestion was significantly higher ($P < 0.001$) than that released from PR12 and PR18. No significant differences were observed between PR12 and PR18 after gastric digestion ($P > 0.05$). Intestinal digestion brought about an increase in the amount of low molecular weight peptides in all of the samples. Once again, the concentration of peptides detected after the intestinal digestion step of PR24 was significantly higher than that measured in PR12 and PR18 ($P < 0.05$;
Fig. 1). No significant differences ($P > 0.05$) were found between peptide concentrations in PR12 and PR18.

3.2. Effect of ripening on the peptidomic profile of Parmigiano-Reggiano (PR) WSPE peptide fractions

Overall, 278 unique peptides were identified in the three PR WSPE peptide fractions at different ripening time-points (Table S1). According to the TNBS assay data, the PR24 sample contained the highest amount of peptides (257 peptides), whereas the amount of peptides identified in PR12 and PR18 samples was similar (84 and 72 peptides, respectively) and lower compared to the number observed in the PR24 sample (Fig. 2A). The majority of the peptides identified in PR12 and PR18 samples were from β-casein (63.1% and 58.3%, respectively), whereas the remaining identified peptides were from $\alpha_{S1}$-casein (Fig. 2A). PR24 sample also contained peptides released from $\alpha_{S2}$-casein (13.6% of total peptides). The Venn diagram (Fig. 3A) shows that 64 peptides (23% of total peptides) were commonly found in all the PR samples. Five peptides (1.8% of total peptides) were in common between PR12 and PR18, whereas the PR24 sample contained 191 (68.7% of total peptides) unique peptides. Among the 84 peptides identified in PR12, 15 of them (~18% of peptides identified in PR12) were found only in this sample.

The peptidomic profile of the three PR samples highlighted the paramount importance of LAB CEPs in the proteolysis of cheese caseins, as indicated by the cleavage sites in the N-terminal region of $\alpha_{S1}$-casein. Peptidic bonds at the H$_8$–Q$_9$, Q$_9$–G$_{10}$, Q$_{13}$–E$_{14}$, E$_{14}$–V$_{15}$, L$_{16}$–N$_{17}$ and F$_{23}$–F$_{24}$ positions are well-known cleavage sites for LAB CEPs (Solieri et al., 2018; Jensen, Vogensen, & Ardö, 2009; Hebert et al., 2008). Another trait indicating the action of CEPs in the production of these peptides is that the majority of cleavage sites in β-casein (61.8%, 63.8% and 74.0% in the PR12, PR18 and PR24, respectively) have been previously reported to be typical for several CEPs from Lactobacillus casei, Lactobacillus rhamnosus, Lactobacillus delbrueckii, Lactobacillus paracasei, Lactobacillus lactis and Lactobacillus helveticus (Solieri et al., 2018; Hebert et al., 2008;
Lozo et al., 2011; Juillard et al., 1995; Miyamoto et al., 2015). It is important to emphasize that a complex and dynamic population of LAB, which thoroughly changes during ripening, is characteristic of PR cheeses (Solieri et al., 2012).

The action of the extracellular proteinase and intracellular peptidases in Lactobacillus can explain the presence of the high number of unique peptides in PR24. Several studies showed that the LAB population decreases as the ripening of PR proceeds (Solieri et al., 2012; Coppola et al., 1999). LAB cell lysis may release cell envelope-proteases and intracellular peptidases in the matrices, which can then enhance the proteolysis of caseins or caseins peptides. Indeed, the bacterial lysis decreases the number of vital LAB and therefore the amount of peptides translocated into the cells.

3.3. Effect of in vitro digestion on the peptidomic profile of digested Parmigiano-Reggiano (PR) peptide fractions

UHPLC/HR-MS analysis revealed different peptide profiles for the peptide fractions from the PR samples after in vitro gastro-intestinal digestion (Figs. 2B and 3B). In each sample, the majority of the peptides were from β-caseins (47.8, 40.4 and 38.2% of the total identified peptides in digested PR12, PR18 and PR24, respectively) followed by α\textsubscript{S1}-casein (29.3, 30.9 and 32.6% of the total identified peptides in digested PR12, PR18 and PR24, respectively) (Fig. 2B).

The Venn diagram indicated that 158 identified peptides (corresponding to the 33.7% of total identified peptides) co-existed in the three PR peptide fractions after in vitro digestion (Fig. 3B). There were 115, 31 and 24 peptides exclusively found in digested PR12, PR18 and PR24, respectively. The highest similarity in peptide profiles was found between digested PR18 and PR24 samples, with 258 common peptides. Only 22, 21 and 37 peptides were commonly found in undigested and digested samples from PR12, PR18 and PR24 peptide fractions, respectively (supplementary Table S1). Among these peptides, 14 (30.4% of total peptides) were commonly found in each of the undigested and digested samples (supplementary Fig. S1). The peptides RELEEL, ELEEL, DKIHPF, LVYPFP, EMPFPK,
SLVYPFPPIP, LVYPFPPIP, YPFPPPIP, VLPVPQK and AVYPQR were from β-casein whereas the peptides FVAPFPE, VAPFPE, EIVPN and YKVPQ were from αS1-casein. It is not surprising that most of these peptides contain a PXP sequence or a proline residue near to the carboxylic end. These peptide structural motifs increase the resistance to gastro-pancreatic proteases action, which do not readily hydrolyze proline-containing peptides (Tagliazucchi, Helal, Verzelloni, Bellesia, & Conte, 2016). Indeed, most of these PXP-containing peptides have been found after in vivo or in vitro gastro-intestinal digestion of milk or milk proteins (Tagliazucchi et al., 2016; Tagliazucchi, Martini, Shamsia, Helal, & Conte, 2018; Boutrou et al., 2013; Boutrou, Henry, & Sanchez-Rivera, 2015). The peptides found only in undigested cheeses were likely degraded during in vitro gastro-intestinal digestion.

3.4. Effect of ripening on the evolution and fate of bioactive peptides in Parmigiano-Reggiano cheeses

Peptides in the undigested PR peptide fractions from WSPE were compared for sequence matches with the milk bioactive peptide database MBPDB (Nielsen et al., 2017). Across the categories, 26 peptides in undigested PR samples (Table 1) shared the same sequence (100% of homology) with functional peptides previously reported to have various bioactivities.

Among the peptide fractions from undigested WSPE, the PR24 sample contained the highest amount of bioactive peptides (26 peptides) respect to PR18 and PR12 samples (12 and 11 peptides, respectively) (Table 1 and supplementary Figure S2A). The Venn diagram (supplementary Fig. S2A) shows that 11 bioactive peptides (42.3% of total peptides) were commonly found in all the PR samples, whereas 14 bioactive peptides were uniquely present in the PR24 sample (Table 1). Nine of the identified bioactive peptides were angiotensin converting-enzyme (ACE) inhibitors, 5 peptides were anti-microbial, 1 was a di-peptidyl-peptidase IV (DPPIV) inhibitor, 1 was anxiolytic, 1 was antioxidant and 9 were multifunctional bioactive peptides. Considering also the multifunctional bioactive peptides, 9 were anti-microbial essentially active against pathogenic
Gram-negative bacteria such as *Escherichia coli*, *Cronobacter sakazakii* and *Staphylococcus aureus* (Sedaghati, Ezzatpanah, Mashhadi Akbar Boojar, Tajabadi Ebrahimi, & Kobarfard, 2015; Birkemo, O’Sullivan, Ross, & Hill, 2009; Kent et al., 2012). The ability of LAB present in PR cheese to produce anti-microbial peptides from hydrolysis of milk proteins may confer a competitive advantage, thus decreasing the risk of the growth and survival of food-borne pathogens (Settanni, & Moschetti, 2010).

Of the 11 commonly identified peptides, the relative abundance of 10 was significantly higher in P24 sample respect to P12 and P18 samples (*P* < 0.05). In contrast, the ACE-inhibitory peptide FFVAPFPEVFGK displayed a decreasing trend during ripening with the highest relative abundance found in P12 sample (*P* < 0.05). The ACE-inhibitory peptide SKVLPVPQ was not detected in sample P12 but showed an increasing trend during ripening with the highest relative abundance found in sample P24 (*P* < 0.05).

3.5. Effect of in vitro digestion on the evolution and fate of bioactive peptides in Parmigiano-Reggiano cheeses

The bioactive peptide profile varied in the PR samples after *in vitro* gastro-intestinal digestion (Table 2). Globally, 52 peptides with 100% of homology with previously reported functional peptides were identified in digested PR samples (Table 2). The majority (75%) of total identified bioactive peptides (39 peptides) were commonly found in the three digested PR samples (Table 2 and supplementary Fig. S2B). Most of the identified bioactive peptides were ACE-inhibitors (17 peptides) and multifunctional peptides (16 peptides). The other identified bioactive peptides were anti-microbial (7 peptides), DPPIV-inhibitors (4 peptides), antioxidant (2 peptides), opioid (2 peptides), cathepsin B-inhibitors (2 peptides), prolyl-endopeptidase-inhibitor (1 peptide) and immunomodulatory (1 peptide). Three bioactive peptides (LHLPLP, HLPLP and AYFYPEL) were already reported after *in vitro* digestion of PR cheese at 12 months of ripening (Basiricò et al.,
2015), whereas the other bioactive peptides were identified in digested PR cheeses for the first time in this study.

The resulting data from semi-quantitative analysis demonstrated that the majority of identified bioactive peptides were not present at a constant level after digestion with respect to the ripening time, but each peptide showed a characteristic trend. Bioactive peptides identified after in vitro digestion can be clustered into 5 different groups as a function of the evolutive trend respect to the ripening time (Table 2).

The first group was represented by bioactive peptides whose release after in vitro digestion continuously increased according to the ripening time (Table 2). This group was mainly characterized by the presence of ACE-inhibitory peptides (10 bioactive peptides out of 13). Most of these peptides showed low or very low IC$_{50}$ values against ACE. The peptides LHLPLPL, LHLLP and YKVPQL have been reported to reduce hypertension in spontaneously hypertensive rats (SHR) (Quirós et al., 2007; Maeno, Yamamoto, & Takano, 1996; Miguel, Recio, Ramos, Delgado, & Aleixandre, 2006). Peptides LHLPLP, YKVPQL and EMPFPK were also found intact in human gastro-intestinal tract (Boutrou et al., 2013).

Peptide LHLPLP was able to resist in vitro gastro-intestinal digestion but it was hydrolyzed to HLPLP by cellular peptidases prior to being transported across Caco-2 cells (Quirós et al., 2008; Tagliazucchi et al., 2006). The latter can actually be absorbed by intestinal cells and has been found in human plasma after oral administration (Van Platerink et al., 2006). It has been suggested that the peptide LHLPLP, released after in vitro gastro-intestinal digestion of Grana-Padana cheese, may be partially responsible for the blood pressure lowering effect observed in vivo after diet enrichment with Grana-Padana cheese (Stuknite et al., 2015; Crippa et al., 2018).

The second group was characterized by bioactive peptides whose release after in vitro digestion increased according to the ripening time reaching a plateau after 18 months of ripening (Table 2). This group contained the majority of anti-microbial peptides and some ACE-inhibitory peptides with demonstrated in vivo activity on spontaneously hypertensive rats (SHR) and low IC$_{50}$ values.
The peptide AVPYPQR was able to decrease the blood pressure in SHR and behaved as a multifunctional bioactive peptide also showing anti-microbial, anticoagulant and antioxidant activities (Karaki et al., 1990; Tonolo et al., 2018; Tu et al., 2019). The third group was characterized by bioactive peptides the release of which after in vitro digestion increased according to the ripening time reaching a maximum value at 18 months of ripening (Table 2). To this group belonged peptides with different biological activities. The peptide AYFYPEL presented a very low IC_{50} value against ACE and was able to reduce blood pressure in SHR (Contreras, Carrón, Montero, Ramos, & Recio, 2009). The fourth group was represented by bioactive peptides whose release after in vitro digestion decreased according to the ripening time (Table 2). This group was characterized for the presence of the peptide YPFPGPI (also known as β-casomorphin-7) and its precursors. Some ACE-inhibitory peptides were also found in this group but, with the exception of YPFPGPIPN, they displayed higher IC_{50} values. Finally, the last group contained peptides whose amount after in vitro digestion remained constant throughout ripening (Table 2).

3.5. Quantification of YPFPGPI, VPP and IPP in the peptide fractions of WSPE and digested samples of Parmigiano-Reggiano (PR)

Three peptides, namely VPP, IPP and YPFPGPI with documented in vivo effect on humans were quantified in undigested and digested PR samples. The tripeptides VPP and IPP received particular consideration since several in vivo studies confirmed their antihypertensive effect on SHR and mildly hypertensive patients (Cicero, Fogacci, & Colletti, 2017; Fitzgerald, Murray, & Walsh, 2004). Vice versa, different studies have suggested adverse effects of YPFPGPI (β-casomorphin-7) on human health, including cardiovascular diseases, diabetes and digestive disorders (Asledottir et al., 2018).
VPP and IPP have been detected in the WSPE peptide fractions from undigested PR samples at each ripening time (Table 3). The amount of VPP and IPP found in the 12-month ripened PR were 6.87 ± 0.68 and 1.63 ± 0.82 mg kg\(^{-1}\), respectively. These data are in accordance with the range reported by Basiricò et al. (2015) in PR sample at 12 months of ripening. The amount of VPP and IPP increased in the sample at 18 months of ripening, reaching a concentration of 11.34 ± 0.21 and 4.24 ± 2.85 mg kg\(^{-1}\), respectively. After that, we observed a strong decline in the concentration of VPP and IPP at 24 months of ripening (4.52 ± 0.28 and 0.66 ± 0.05 mg kg\(^{-1}\), respectively).

Peptide YPFPGPI, in contrast, was not detected in any undigested PR sample. This is consistent with the report of De Noni, & Cattaneo (2010), who did not observe YPFPGPI in Grana Padano cheese at 10, 17 or 25 months of ripening. These results suggested that LAB proteases and peptidases are not able to release β-casomorphin-7 during cheese ripening.

As shown in Table 3, at the end of the \textit{in vitro} gastro-intestinal digestion, the VPP content of PR12 and PR18 remained almost unchanged. Moreover, the quantitative analysis mainly showed an increase in the content of IPP in both the samples (\(P<0.05\)). In contrast, we observed a significant decrease (\(P<0.05\)) in VPP concentrations after \textit{in vitro} digestion in the PR24 sample, whereas the amount of IPP was unaltered.

β-casomorphin-7, which was not present in the cheese WSPE, was released during \textit{in vitro} digestion of PR samples (Table 3). Previous research highlighted the ability of gastro-intestinal proteases to release β-casomorphin-7 during \textit{in vitro} digestion of milk β-casein variant A1 (Asledottir et al., 2018). The concentration of YPFPGPI after \textit{in vitro} digestion decreased during ripening, with the highest concentration found in digested PR12 sample.

4. Conclusion

According to the data reported in this study, ripening of PR cheese has an important influence in the release of bioactive peptides and the \textit{in vitro} digestion further increased their number in the PR samples. Most of them were found in all of the samples, but in different amounts. Interestingly, they
can be clustered accordingly to ripening time and bioactivities. For example, the majority of the bioactive peptides showing an increasing trend after digestion, as a function of the ripening time, were potent ACE-inhibitory peptides. By contrast, most of the identified anti-microbial peptides reached a plateau after 18 months of ripening. Moreover, the opioid peptides \( \beta \)-casomorphin-7 and its precursor displayed a typical behavior with a decreasing trend after \textit{in vitro} digestion as a function of the ripening time. The present study suggests possible differences in the biological effect after ingestion of PR cheese as a function of the ripening time. The major driving force for consumers to choose a cheese with different ripening times is the organoleptic characteristics but, nevertheless, the peptide profile and bioactivities may also change.
Author contributions

SM, AC and DT conceived and designed the study. SM performed the in vitro digestion and bioactivity experiments. SM and DT performed the peptidomic experiments and the bioinformatic analysis. DT wrote the manuscript. SM and AC critically revised the manuscript. All the authors read the manuscript and discussed the interpretation of results.
Acknowledgements

The authors acknowledge the Fondazione Cassa di Risparmio di Modena for funding the HPLC-ESI-Q Exactive Hybrid Quadrupole-Orbitrap Mass Spectrometer system at the Centro Interdipartimentale Grandi Strumenti (CIGS).
Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Figure captions

**Fig. 1.** Effect of ripening time and *in vitro* digestion on the peptide concentrations in Parmigiano-Reggiano (PR). The total amount of peptides was expressed as mmol of leucine equivalent per g of cheese. WSPE means water-soluble peptide extracts and represent the peptide fractions obtained after ultrafiltration (< 3 kDa) of water-soluble peptides extracted from un-digested PR samples. PR12: Parmigiano-Reggiano at 12 months of ripening. PR18: Parmigiano-Reggiano at 18 months of ripening. PR24: Parmigiano-Reggiano at 24 months of ripening. Values are means of data from three independent digestions ± standard deviation (SD). Different letters indicate significantly different values (*P* < 0.05)

**Fig. 2.** Number of unique peptides identified in the Parmigiano-Reggiano (PR) peptide fractions.

(A) Number of peptides in un-digested PR peptide fractions at 12 (PR12), 18 (PR18) and 24 (PR24) months of ripening. (B) Number of peptides in *in vitro* digested PR peptide fractions at 12 (PR12), 18 (PR18) and 24 (PR24) months of ripening. The incidence of the different milk proteins on the released peptides is also shown.

**Fig. 3.** Venn diagrams of peptides obtained from Parmigiano-Reggiano (PR) peptide fractions. (A) Venn diagram created with all the identified peptides in un-digested PR peptide fractions at 12 (WSPE PR12), 18 (WSPE PR18) and 24 (WSPE PR24) months of ripening (see on line supplementary material Tables S1 for the peptide sequences). (B) Venn diagram created with all the identified peptides in digested PR peptide fractions at 12 (D PR12), 18 (D PR18) and 24 (D PR24) months of ripening (see on line supplementary material Tables S1 for the peptide sequences).
Table 1. Relative amount of bioactive peptides identified in water-soluble extract (WSPE) peptide fractions from Parmigiano Reggiano samples at 12 (PR12), 18 (PR18) and 24 (PR24) months of ripening with previously demonstrated bioactivity.

*Abbreviations are: ACE, angiotensin converting enzyme; DPPIV, dipeptidyl peptidase IV; CN, casein.

One code letter was used for amino acid nomenclature. Potential bioactivities were achieved from MBPDB databases (Nielsen et al., 2017). Anti-hypertensive activity was measured on spontaneously anti-hypertensive rats. Multifunctional peptides were labelled with superscript letters: aantioxidant activity; bantimicrobial activity; cinmunomodulator; dACE-inhibitory activity.

Relative amount was expressed as the area under the peak (AUP) g⁻¹ of cheese measured from the extracted ion chromatograms (EIC) obtained for each peptide. N.d. means peptide not detected in the sample. Different superscript letters within the same row indicate that the values are significantly different (P<0.05)
