The $K^\pi = 0^+\pi$, $K^\pi = 2^-\pi$, and $K^\pi = 0^-\pi$ bands of $^{20}$Ne are investigated with microscopic structure and reaction calculations via proton and $\alpha$ inelastic scattering off $^{20}$Ne. Structures of $^{20}$Ne are calculated with variation after parity and total angular momentum projections in the antisymmetrized molecular dynamics (AMD). The $K^\pi = 0^+\pi$ and $K^\pi = 0^-\pi$ bands have $^{16}$O + $\alpha$ cluster structures, whereas the $K^\pi = 2^-\pi$ band shows a $^{12}$C + $2\alpha$-like structure. Microscopic coupled-channel calculations of proton and $\alpha$ scattering off $^{20}$Ne are performed by using the proton-nucleus and $\alpha$-nucleus potentials, which are derived by folding the Melbourne $g$-matrix $NN$ interaction with AMD densities of $^{20}$Ne. The calculation reasonably reproduces the observed cross sections of proton scattering at $E_p = 25$–$35$ MeV and $\alpha$ scattering at $E_{\alpha} = 104$–$386$ MeV. Transition properties from the ground to excited states are discussed by reaction analyses of proton and $\alpha$ inelastic processes. Mixing of the $K^\pi = 2^-\pi$ and $K^\pi = 0^-\pi$ bands is discussed by detailed analysis of the $0^+_1 \rightarrow 3^-_1$ and $0^+_1 \rightarrow 3^-_2$ transitions. For the $3^-_2$ state, mixing of the $K^\pi = 0^-\pi$ cluster component in the $K^\pi = 2^-\pi$ band plays an important role in the transition properties.

I. INTRODUCTION

Cluster structure plays an important role in nuclei, in particular, in light-mass regions. A typical cluster structure in $sd$-shell nuclei is $^{16}$O + $\alpha$ cluster structure of $^{20}$Ne [1]. The idea of the $^{16}$O + $\alpha$ cluster structure has been introduced to describe energy levels of the parity-doublet $K^\pi = 0^+_1\pi$ and $K^\pi = 0^-_1\pi$ bands [2], and extended to describe the higher nodal $^{16}$O + $\alpha$ cluster band assigned as the $K^\pi = 0^+_2\pi$ (labeled as $K^\pi = 0^+_n\pi$) band. The structure and $\alpha$-decay properties of $^{16}$O + $\alpha$ cluster states have been intensively investigated with potential models and (semi)microscopic cluster models [1] [3] [14].

In excited states of $^{20}$Ne, further rich phenomena beyond the $^{16}$O + $\alpha$ cluster structure arise from cluster breaking, i.e., internal excitation of $^{16}$O and $\alpha$ clusters. For example, in the $K^\pi = 0^+_2\pi$ band, the cluster breaking is essential to describe deviation from ideal rotational spectra at the band terminal [15] [17]. In addition, $^{12}$C + $2\alpha$ (or $^{12}$C + $8$ Be) cluster structure has been considered to discuss the $K^\pi = 0^+_2\pi$ and $K^\pi = 0^-_2\pi$ bands, in the frameworks of extended cluster models [6] [9] [11] and antisymmetrized molecular dynamics (AMD) [18]. The cluster structures of $^{20}$Ne have been also discussed with mean-field approaches [19] [22]. Moreover, the lowest negative-parity band experimentally assigned as the $K^\pi = 2^-\pi$ band is considered to be a particle-hole state or octupole $Y_{32}$ vibration [11] [16] [19] [21] [23].

It means that two types of negative-parity states appear in low-energy levels of $^{20}$Ne, the mean-field type states in the $K^\pi = 2^-\pi$ band and the $^{16}$O + $\alpha$ cluster states in the $K^\pi = 0^-\pi$ band. The former band arises from the $K^\pi = 2^-\pi$ particle-hole excitation, and the latter is caused by the $K^\pi = 0^-\pi$ excitation of the inter-cluster motion between $^{16}$O and $\alpha$ clusters. In the experimental levels, the $3^-_1$ (5.62 MeV) and $3^-_2$ (7.16 MeV) states are assigned to the $K^\pi = 2^-\pi$ and $K^\pi = 0^-\pi$ bands, respectively. Energy levels and in-band $E2$ transitions in each band have been reproduced well by theoretical calculations with the $(^{16}$O + $\alpha) + (^{12}$C + $8$ Be) coupled-channel orthogonal condition model (CC-OCM) [11] and the deformed-basis AMD (def-AMD) [16]. However, the observed $E3$ transition strength, $B(E3;3^-_1 \rightarrow 0^+_1\pi)$ [24], for the inter-band transition from the $K^\pi = 2^-\pi$ band to the ground band is much larger by one order of magnitude than the theoretical value of CC-OCM, and inconsistent with the simple interpretation of the $K^\pi = 2^-\pi$ band as the particle-hole excitation.

In order to investigate structure and transition properties of the ground and excited bands, electron and hadron scattering experiments have been performed for $sd$-shell nuclei. For $^{20}$Ne, hadron inelastic scattering such as $(p,p')$ and $(\alpha,\alpha')$ have been investigated [25] [31]. Phenomenological reaction analyses of the $(p,p')$ and $(\alpha,\alpha')$ cross sections have suggested again the strong $3^-_1 \rightarrow 0^+_1\pi$ transition consistently with the $B(E3;3^-_1 \rightarrow 0^+_1\pi)$ data determined by $\gamma$ decays, but the $B(E3;3^-_1 \rightarrow 0^+_2\pi)$ values evaluated from hadron scattering show dependence on energies and projectile particles.

In principle, proton and $\alpha$ inelastic scattering can be good probes for transition properties from the ground to excited states provided that reliable reaction analyses are available. Recently, microscopic coupled-channel (MCC) calculations for proton and $\alpha$ scattering have been remarkably developed. In the MCC calculations, matter and transition densities of target nuclei obtained with microscopic structure models are utilized as inputs of coupled-channel reaction calculations in microscopic
folding models (MFMs), in which nucleus-nucleus and α-nucleus potentials are constructed by folding effective NN interactions. In our previous studies [32–35], we have applied the MCC calculations to proton and α scattering off various target nuclei in the p- and sd-shell regions with structure model calculation of AMD. Using the Melbourne g-matrix NN interaction [36], we have succeeded in reproducing (p, p′) and (α, α′) cross sections of various excited states such as cluster and vibration excitations. The Melbourne g-matrix interaction is an effective NN interaction in nuclear medium based on a bare NN interaction of the Bonn B potential [37]. Owing to NN-particle angular momentum projection operator.

In the framework of AMD, an action using AMD densities of 20Ne as structure inputs of the target nucleus. With analyses of the structure and reaction calculations, structures of the ground and excited states in the $K^\pi = 0^+_1$, $K^\pi = 2^-$, and $0^-_1$ bands are investigated. In particular, properties of the $3^-_1$ and $3^-_2$ states and possible mixing of the $K^\pi = 2^-$ and $K^\pi = 0^-_1$ bands are discussed in detail.

The paper is organized as follows. The next section describes the frameworks of the AMD calculation of 20Ne and the MCC approach for proton and α scattering off 20Ne. Structure properties are described in Sec. III and the results of proton and α scattering are shown in Sec. IV. A discussion of the $3^-_1$ and $3^-_2$ states is given in Sec. V. Finally the paper is summarized in Sec. VI.

II. METHOD

A. Structure calculations of 20Ne

We apply the VAP version of AMD to calculate structure of 20Ne. The method is almost the same as those used for studies of 12C and neutron-rich Be isotopes in Refs. [39]–[42]. It is sometimes called AMD+VAP, but we simply call it AMD in the present paper. For comparison, we also apply a 16O + α-cluster model with the generator coordinate method (GCM) [43]–[44].

In the framework of AMD, an A-nucleon wave function is given by a Slater determinant of single-nucleon Gaussian wave functions as

$$\Phi_{AMD}(Z) = \frac{1}{\sqrt{A!}} A(\varphi_1, \varphi_2, ..., \varphi_A),$$

$$\varphi_i = \phi_X \chi_i \tau_i,$$

$$\phi_X(r_j) = \left(\frac{2\nu}{\pi}\right)^{3/4} \exp[-\nu(r_j - X_i)^2],$$

$$\chi_i = \left(\frac{1}{2} + \xi_i\right)\chi_1 + \left(\frac{1}{2} - \xi_i\right)\chi_2.$$  

Here $A$ is the antisymmetrizer, and $\varphi_i$ is the ith single-particle wave function written by a product of spatial ($\phi_X$), spin ($\chi_i$), and isospin ($\tau_i$ fixed to be proton or neutron) wave functions. The width parameter $\nu$ is chosen to be $\nu = 0.19$ fm$^{-2}$ for all nucleons as the same as that used for AMD+VAP calculations of 12C and 16O in Refs. [39]–[45]. Parameters $Z = \{X_1, \ldots, X_A, \xi_1, \ldots, \xi_A\}$, which represent Gaussian centroid positions and nucleon-spin orientations, are optimized by the energy variation for each $J^\pi$ state of 20Ne so as to minimize the energy expectation value $E = \langle \Psi|\hat{H}|\Psi\rangle/\langle \Psi|\Psi\rangle$ with respect to the parity and total angular momentum projected wave functions $\Psi = P_{MK} Z \Phi_{AMD}(Z)$. Here $P_{MK}$ is the parity and total angular momentum projection operator.

The VAP is performed for $J^\pi = \{0^+, 2^+, 4^+\}$, $\{2^-, 3^-, 4^-\}$, and $\{1^-, 3^-\}$ by choosing $K = 0$, $K = 2$, and $K = 0$, respectively. For each band, firstly the band-head state is obtained by the VAP from a randomly chosen initial state, and then higher angular momentum states are calculated by the VAP from the initial wave function projected from $\Phi_{AMD}(Z)$ obtained for the band-head state. Totally eight AMD wave functions $\Phi_{AMD}(Z^{(m)})$ ($m = 1, \ldots, 8$) are obtained after the VAP, and all of them are superposed to obtain final wave functions of the ground and excited states of 20Ne. Namely, for the basis wave functions $P_{MK} Z \Phi_{AMD}(Z^{(m)})$ projected from the intrinsic wave functions, the diagonalization of Hamiltonian and norm matrices is done to obtain $J^\pi$ states. The diagonalization is done with respect to $K$ and $m$ meaning the $K$-mixing and the configuration ($m$) mixing. As a result of the diagonalization, $J^\pi = \{0^+, 2^+, 4^+\}$ states in the $K^\pi = 0^+_1$ band are also obtained.

The effective nuclear interactions used in the present AMD calculation are the same as those in Refs. [39]–[45]. The MV1 (case 1) central force [46] with the parameters ($b, h, m) = (0, 0, 0.62)$ and the spin-orbit term of the G3RS force [47]–[48] with the strength parameters $u_{\text{str}} \equiv u_l = -u_{1l} = 3000$ MeV are used. The Coulomb force is also included.

The AMD calculation of 20Ne with this set of interactions obtains reasonable results of energy levels and in-band transitions of the $K^\pi = 0^+_1$, $K^\pi = 0^-_1$, and $K^\pi = 0^-_2$ bands but it gives a higher energy of the $K^\pi = 2^-$ band than the $K^\pi = 0^-_1$ band, which is inverse ordering of the $K^\pi = 2^-$ and $K^\pi = 0^-_1$ bands compared with experimental levels. The excitation energy of the $K^\pi = 2^-$ band is sensitive to the strength
of spin-orbit interactions as discussed in Refs. [16, 19]. We can improve the \( K^\pi = 2^- \) energy with a slight modification of the spin-orbit strength and obtain the correct ordering of the \( K^\pi = 2^- \) and \( K^\pi = 0^- \) bands. In order to discuss possible state mixing between the \( K^\pi = 2^- \) and \( K^\pi = 0^- \) bands, we also use a strength of \( u_{ls} = 3400 \text{ MeV} \) modified from the original value \( u_{ls} = 3000 \text{ MeV} \), and perform diagonalization of the basis AMD wave functions already obtained by VAP with the default strength \( (u_{ls} = 3000 \text{ MeV}) \). We label the AMD calculation with the default and modified strengths, \( u_{ls} = 3000 \text{ MeV} \) and \( 3400 \text{ MeV} \), as AMD and AMD-Isl34, respectively.

In addition to the AMD calculation, a structure calculation of the \( ^{16}\text{O} + \alpha \)-cluster model (CM) is also performed with GCM. In the GCM framework, the Brink-Bloch \( ^{16}\text{O} + \alpha \)-cluster wave functions [19] with inter-cluster distances of 1, 2, . . ., 10 fm are superposed. In the CM calculation, we adopt the same parametrization as that used in the \( ^{16}\text{O} + \alpha \)-cluster model calculation with the resonating group method in Refs. [7, 8]. That is, the width parameters \( \nu \) of \( \nu \) groups and \( \nu \) of \( \nu \) bands are adopted in the MCC calculation, and those in the \( K^\pi = 0^+ \), \( K^\pi = 0^- \), and \( K^\pi = 0^- \) bands are used in the MCC+CM calculation. In order to reduce model ambiguity from the structure calculation, the theoretical transition densities obtained by the structure calculations are renormalized in application to the MCC calculations so as to fit the experimental transition strengths as \( \rho^{\rm exp}(r) \rightarrow f^{\rm exp} \rho^{\rm cm}(r) \). Here the factor \( f^{\rm exp} \) is determined with the squared ratio of experimental \( (B^{\exp}(E\lambda)) \) to theoretical \( (B^{\text{th}}(E\lambda)) \) strengths as \( f^{\text{exp}} = \sqrt{B^{\exp}(E\lambda)/B^{\text{th}}(E\lambda)} \) for known values of \( B^{\exp}(E\lambda) \), and \( f^{\text{exp}} = 1 \) (no renormalization) is used for unknown cases.

**B. MCC calculation of proton and \( \alpha \) scattering off \(^{20}\text{Ne}\)**

Elastic and inelastic cross sections of proton and \( \alpha \) scattering off \(^{20}\text{Ne}\) are calculated with the MCC approach as done in our previous studies of Refs. [32, 34]. For the details of the reaction calculations, the reader is referred to those references.

The nucleon-nucleus potentials are constructed in a MFM, where the diagonal and coupling potentials are calculated by folding the Melbourne \( g \)-matrix \( NN \) interaction [36] with matter and transition densities of the target nucleus. The \( \alpha \) potentials are obtained in an extended nucleon-nucleus folding (NAF) model [50] by folding the calculated nucleon-nucleus potentials with an \( \alpha \) density.

The Melbourne \( g \)-matrix is an effective \( NN \) interaction derived with a bare \( NN \) interaction of the Bonn B potential [37]. It contains energy and density dependences with no adjustable parameter, and works well in application for systematic description of proton elastic and inelastic scattering off various nuclei at energies \( E_p = 40-300 \text{ MeV} \) [34, 36, 51, 53] and also \( \alpha \) elastic and inelastic scattering at energies \( E_\alpha = 100-400 \text{ MeV} \) [32, 33, 39, 50, 54]. In the present calculation of the proton-nucleus potentials, the spin-orbit term of the potential is not taken into account to avoid complexity as in Refs. [34, 35].

As structure inputs for the target nucleus, the matter \( (\rho(r)) \) and transition \( (\rho^{\text{cm}}(r)) \) densities of \(^{20}\text{Ne}\) obtained by the AMD and CM calculations are used. \( J^\pi = 0^+ \), \( 1^- \), \( 2^+ \), \( 3^- \), and \( 4^+ \) states in the \( K^\pi = 0^+ \), \( K^\pi = 2^- \), \( K^\pi = 0^- \), and \( K^\pi = 0^- \) bands and \( \lambda \leq 4 \) transitions between them are adopted in the MCC+AMD calculation, and those in the \( K^\pi = 0^+ \), \( K^\pi = 0^- \), and \( K^\pi = 0^- \) bands are used in the MCC+CM calculation.

**III. STRUCTURE OF \(^{20}\text{Ne}\)**

The calculated energy levels of \(^{20}\text{Ne}\) obtained by AMD, AMD-Isl34, and CM are shown in Figs. 1(a), (b), and (c), respectively, and the experimental levels assigned to the \( K^\pi = 0^+ \), \( K^\pi = 2^- \), \( K^\pi = 0^- \), and \( K^\pi = 0^- \) bands are shown in Fig. 1(d). The AMD calculation reasonably describes the experimental energy levels of the \( K^\pi = 0^+ \), \( K^\pi = 0^- \), and \( K^\pi = 0^- \) bands (Fig. 1(a)). However, it overestimates the \( K^\pi = 2^- \) levels and gives inverse ordering of the \( K^\pi = 2^- \) and \( K^\pi = 0^- \) bands compared with the experimental levels. In the AMD-Isl34 result with a modified spin-orbit strength (Fig. 1(b)), the excitation energy of the \( K^\pi = 2^- \) band comes down lower than the \( K^\pi = 0^- \) band, and correct ordering of the two negative-parity bands is obtained. As a result, the state mixing between the \( K^\pi = 2^- \) and \( K^\pi = 0^- \) bands occurs in the \( 3^- \) states in the AMD-Isl34 case. This state mixing is not obtained in the default AMD calculation.

In the result of CM, the energy levels of the \( K^\pi = 0^+ \), \( K^\pi = 0^- \), and \( K^\pi = 0^- \) bands are reproduced, but the \( K^\pi = 2^- \) band is missing because the \(^{16}\text{O} + \alpha \) model space contains only axial symmetric configurations with pure \( K = 0 \) components.

In Table I, the calculated values of excitation energies \( (E_x) \) and root-mean-square radii \( (R) \) of \(^{20}\text{Ne}\) obtained with AMD and CM are listed together with the experimental excitation energies. Experimentally, the \( J^\pi = \{0^+, 2^+, 4^+_1\} \), \( \{2^-_\alpha, 3^-_\alpha, 4^-_\alpha\} \), and \( \{1^-_\alpha, 3^-_\alpha\} \) states with strong in-band \( E2 \) transitions are assigned to the \( K^\pi = 0^+ \), \( K^\pi = 2^- \), and \( K^\pi = 0^- \) bands, respectively. Following this experimental assignment, we use the label \( 3^-_1 \) \( (3^-_2) \) for the \( K^\pi = 2^- \) \( (K^\pi = 0^-) \) band member of the theoretical results. The negative-parity states in the \( K^\pi = 0^- \) band have large radii compared to the \( K^\pi = 0^+ \) and \( K^\pi = 2^- \) bands because of a spatially developed \(^{16}\text{O} + \alpha \) structure.

Figure 2 shows intrinsic density distribution of the basis AMD wave functions for the band-head states, \( 0^+_1 \) \( (K^\pi = 0^+ \) state shows an \(^{16}\text{O} + \alpha \) like structure, whereas the \( 1^-_1 \) \( (K^\pi = 0^- \) state has the most prominent \(^{16}\text{O} + \alpha \) cluster structure. Qualitatively, these two bands
TABLE I: Excitation energies ($E_x$) and root-mean-square matter radii ($R$) of $^{20}$Ne. The calculated values obtained with the AMD and CM calculations and the experimental values are listed. The experimental value of the point-proton rms radius of the ground state is $R = 2.888(2)$ fm from the charge radius data[56].

| $J^n$ | exp $E_x$ (MeV) | AMD $E_x$ (MeV) | $R$ (fm) | exp $E_x$ (MeV) | CM $R$ (fm) |
|------|----------------|----------------|--------|----------------|-------------|
| $0^+_1$ | 0 | 0.0 | 3.01 | 0.0 | 2.95 |
| $2^+_1$ | 1.634 | 1.1 | 3.01 | 1.0 | 2.94 |
| $4^+_1$ | 4.248 | 3.5 | 2.99 | 3.3 | 2.92 |
| $2^-_1$ | 4.967 | 8.2 | 2.94 |

| $4^-_1$ | 7.004 | 10.4 | 2.97 |
| $0^-_1$ | 5.788 | 5.8 | 3.20 | 4.7 | 3.20 |
| $3^-_2$ | 7.156 | 7.5 | 3.19 | 6.4 | 3.22 |

FIG. 2: Density distribution of intrinsic wave functions for the band-head states, (a) $0^+_1$, (b) $2^-_1$, and (c) $1^-_1$ of the $0^+_1$, $K^n = 2^-$, and $K^n = 0^-_1$ bands of $^{20}$Ne obtained with AMD. The density projected onto X-Z, Y-Z, and Y-X planes are shown in left, middle, and right panels, respectively. Intrinsic axes are chosen as $\langle ZZ \rangle \geq \langle YY \rangle \geq \langle XX \rangle$ and $\langle XY \rangle = \langle YZ \rangle = \langle ZX \rangle = 0$. Cluster model, but strictly speaking it is not correct because the $0^+_1(K^n = 0^+_1)$ state contains a deformed $^{16}$O cluster showing a significant component of internal excitation of the cluster. The $K^n = 2^-$ band shows a...
TABLE II: $E2$ transition strengths for in-band transitions in the $K^\pi = 0^+_1$, $K^\pi = 2^-$, and $K^\pi = 0^+_1$ bands, $E\lambda$ and isoscalar dipole (IS1) transition strengths to the ground state, and electric quadrupole moment ($Q$) of the $2^+_1$ state. The theoretical values obtained by the AMD (default), AMD-ls34 (modified spin-orbit strength), and CM calculations are listed together with the experimental values from Refs. [24, 57]. Theoretical values of the ($^{16}O + \alpha$)+($^{12}C + ^3$Be) coupled-channel OCM (CC-OCM) [11] and the deformed-basis AMD (def-AMD) [16] are also shown. In addition, the $B(E\lambda)$ values reduced from inelastic scattering data of $(e,e')$ [58], $(p,p')$ at 800 MeV [29], 24.5 MeV [26, 28], and $(d,d')$ at 52 MeV [28] are also shown. The units are $e^2$fm$^4$ for $B(E\lambda)$, $e^2$fm$^2$ for $B(IS1)$, and $e$fm$^2$ for $Q$.

| Transition | Exp. [24, 57] | CM | AMD | AMD-ls34 | CC-OCM [11] | def-AMD [16] |

$^{12}$C + 2\alpha-like structure with an axial asymmetric shape, where two \alpha clusters are formed around a $^{12}$C cluster. As a result of formation of the $^{12}$C cluster, the $K^\pi = 2^-$ band gains the spin-orbit interaction. Compared to the $K^\pi = 0^-_1$ band, the $K^\pi = 2^-$ band has a compact structure with a mean-field aspect of particle-hole excitation on the protonate state. It means that the $K^\pi = 2^-$ band has the duality of cluster and mean-field features.

The results of electric ($E\lambda$) and isoscalar dipole (IS1) transition strengths and electric quadrupole moment ($Q$) are shown in Table I. The theoretical values obtained by AMD, AMD-ls34, and CM are shown together with the experimental data from Refs. [24, 57]. Moreover, theoretical values of the CC-OCM [11] and def-AMD [16] calculations are also shown for comparison. In addition to the experimental $B(E\lambda)$ measured by \gamma decays, the values reduced from $(e,e')$ scattering data [58] and those evaluated from inelastic scattering of $(p,p')$ [26, 28, 24] and $(d,d')$ [28] are also shown in Table I. Note that uncertainty remains in the evaluation with hadron scattering because it relies on the phenomenological reaction analysis and shows significant dependences on energy and projectile.

The observed in-band $E2$ transitions in the $K^\pi = 0^+_1$, $K^\pi = 2^-$, and $K^\pi = 0^+_1$ bands are reproduced well by the ADM calculation. The agreement is almost the same quality as other theoretical calculations of CC-OCM and def-AMD. The experimental $Q$ moment of the $2^+_1$ state is somewhat underestimated by the AMD and CM calculations.

For the $E4$ transition in the $K^\pi = 0^+_1$ band, the strength $B(E4; 4^-_1 \to 0^+_1)$ obtained with the AMD calculation is consistent with the $(e,e')$ scattering, while the CM calculation gives a weaker $E4$ transition. The values evaluated from $(p,p')$ scattering strongly depend on energies and have large uncertainty. For $E3$ transitions from the $K^\pi = 0^-_1$ band, AMD and CM give the remarkably strong $3^-_2 \to 0^+_1$ transition because of the developed $^{16}$O + \alpha-cluster structure. For the transition from the $K^\pi = 2^-$ band, the AMD calculation obtains the weak $3^-_1 \to 0^+_1$ transition as one order of magnitude smaller strength as the $3^-_2 \to 0^+_1$ strength. These AMD results of $B(E3; 3^-_1 \to 0^+_1)$ and $B(E3; 3^-_2 \to 0^+_1)$ are consistent with the CC-OCM calculation, but not consistent
with the observation. The observed $B(E3; 3^{-}_1 \to 0^+_1)$ is much larger than the AMD and CC-OCM results. Moreover, the evaluation from $(p, p')$ and $(d, d')$ scattering suggests the same order transitions to the $3^{-}_1 (K^\pi = 2^-)$ and $3^{-}_2 (K^\pi = 0^-)$ states though uncertainty still remains.

Transition properties from the $0^+_1$ state to the $3^{-}_1 (K^\pi = 2^-)$ and $3^{-}_2 (K^\pi = 0^-)$ states are sensitive to the state mixing between the $K^\pi = 2^-$ and $K^\pi = 0^-$ bands. Let us discuss effects of the state mixing on the $E3$ transition strengths by comparing the AMD-Is34 and AMD results for the cases with and without state mixing, respectively. As shown in Table II, the $B(E3; 3^{-}_1 \to 0^+_1)$ value of AMD-Is34 is as three times large as that of AMD because of mixing of the $K^\pi = 0^-$ cluster component in the $3^{-}_1$ state. On the other hand, the $B(E3; 3^{-}_2 \to 0^+_1)$ value decreases in the AMD-Is34 result compared to AMD because of destructive mixing of the $K^\pi = 2^-$ component in the $3^{-}_2$ state. In order to describe the experimental $B(E3; 3^{-}_1 \to 0^+_1)$, the state mixing case of AMD-Is34 seems more likely than the almost no mixing case of AMD. Such the significant mixing may originate in coupling of the $^{12}\text{C} + 2\alpha$ and $^{16}\text{O} + \alpha$ cluster structures contained in the $K^\pi = 2^-$ and $K^\pi = 0^-$ bands, respectively. As shown in Figs. 4(a), (b), and (c), the AMD and CM calculations reproduce the elastic form factors, and also describe the inelastic form factors to the $2^+_1$ state. The theoretical $2^+_1$ form factors obtained by AMD (CM) are renormalized by $f^{22} = 0.97$ (1.11). The theoretical $3^{-}_1$ form factors obtained by AMD and AMD-Is34 are multiplied by $f^{13} = 2.22$ and 1.30, respectively. The experimental data are those measured by electron scattering [58].

dependence of matter densities is not so strong. The calculated form factors and transition densities are shown in Figs. 4 and 5, respectively. For the $2^+_1 \to 0^+_1$ and $3^{-}_1 \to 0^+_1$ transitions, theoretical values are renormalized with $f^{22}$ determined from the experimental and theoretical $B(\text{E}3) \alpha$ values listed in Table II. The experimental form factors observed by $(e, e')$ scattering are also shown in Figs. 4(a), (b), and (c). The AMD and CM calculations reproduce the elastic form factors, and also describe the inelastic form factors to the $2^+_1$ state. The calculated $4^+_1$ form factors obtained with AMD are in good agreement with the $(e, e')$ data, but those with CM underestimate the data (see Fig. 4(c)).

In the AMD result for $E3$ transitions, clear differences between the $3^{-}_1$ and $3^{-}_2$ states can be seen in the form factors and transition densities, which are shown by red

![FIG. 3: Matter densities of $^{20}\text{Ne}$ calculated with AMD.](image)

![FIG. 4: Elastic and inelastic form factors of $^{20}\text{Ne}$ calculated with AMD (red solid lines) and CM (green dashed lines) compared with the experimental data (circles). The $3^{-}_1$ and $3^{-}_2$ form factors calculated with AMD-Is34 (blue dotted lines) are also shown in panels (e) and (f), respectively. The theoretical $2^+_1$ form factors obtained by AMD (CM) are renormalized by $f^{22} = 0.97$ (1.11). The theoretical $3^{-}_1$ form factors obtained by AMD and AMD-Is34 are multiplied by $f^{13} = 2.22$ and 1.30, respectively. The experimental data are those measured by electron scattering [58].](image)
IV. PROTON AND $\alpha$ SCATTERING

The MCC calculations with AMD and CM are performed for proton scattering at incident energies of $E_p = 25$, 30, and 35 MeV and $\alpha$ scattering at $E_\alpha = 104$, 146, and 386 MeV. To see the coupled channel (CC) effect, the one-step calculation of the distorted wave born approximation (DWBA) is also performed using the AMD densities. As described previously, the theoretical transition densities are renormalized by multiplying the factors ($f^{\text{tr}}$), which are determined as $f^{\text{tr}} = \sqrt{B_{\exp}(E\lambda)/B_{\text{th}}(E\lambda)}$ to fit the experimental data of $B(E2; 2_1^+ \rightarrow 0_1^+)$, $B(E2; 4_1^+ \rightarrow 2_1^+)$, $B(E2; 3_2^- \rightarrow 1_1^-)$, and $B(E3; 3_1^- \rightarrow 0_1^+)$. For the $E2; 2_1^+ \rightarrow 2_1^+$ transition, $f^{\text{tr}}$ is chosen to adjust the theoretical $C(Q)$ to the experimental value. For other transitions, $f^{\text{tr}} = 1$ (no renormalization) is used.

The calculated cross sections of proton elastic and inelastic scattering are shown in Fig. 8 compared with the experimental data. The MCC+AMD (red solid lines) and MCC+CM (green dashed lines) reproduce the $0_1^+$ and $2_1^+$ cross sections data well at the first and second peaks. For the $4_1^+$ cross sections, the observe data do not show clear peak structures enough to discuss diffraction patterns. The MCC+AMD reasonably reproduces the global amplitudes of the $4_1^+$ data, while the MCC+CM gives smaller $4_1^+$ cross sections than MCC+AMD and the data because of the weaker $E4$ transition than AMD result. The $1_1^-$ cross sections are reasonably described with the MCC+AMD and MCC+CM calculations except for forward angles. As for the $3_1^-$ cross sections, the MCC+AMD reproduces the first peak amplitude of the data, but somewhat overestimates the second peak amplitude. In comparison of the DWBA+AMD (blue dotted lines) and MCC+AMD (red solid lines) calculations, non-negligible CC effects are seen in this energy range $E_p = 25$–35 MeV except for the $3_1^-$ state.

The $\alpha$ elastic and inelastic cross sections are shown in Fig. 7. The calculated cross sections are compared with the experimental data. For the elastic scattering (Fig. 7(a)), the $E_\alpha = 104$ MeV data from Ref. [30] are reproduced well by MCC+AMD (red solid lines) and MCC+CM (green dashed lines) except for backward angles, whereas the $E_\alpha = 386$ MeV data from Ref. [31] are about two times smaller than the present MCC calculations. We do not know the reason for this apparent inconsistency, but uncertainty from the present reaction model is unlikely because its applicability to $\alpha$ elastic scattering at $E_\alpha = 100$–400 MeV has been already examined for various target nuclei [32, 33, 50, 51]. Therefore, it is likely that the $E_\alpha = 386$ MeV data in Ref. [31] contains uncertainty of the normalization. Assuming the normalization to be an overall factor of two, we multiply the original $\alpha$ and $(\alpha,\alpha')$ data of Ref. [31] by this factor, and obtain excellent agreement of the calculations with the $\alpha$ data as shown in Fig. 7(a). Also the $2_1^+$ cross sections at $E_\alpha = 104$–386 MeV are well reproduced by the MCC+AMD and MCC+CM calcula-

FIG. 5: Transition densities of $^{20}$Ne calculated with AMD and CM. Theoretical values obtained by AMD (CM) for the $2_1^+$ state are renormalized by $f^{\text{tr}} = 0.97 \,(1.11)$, and those for $3_1^-$ state are multiplied by $f^{\text{tr}} = 2.22$. 

lines of Figs. 4(e), 4(f), and 5(d). The $3_1^-$ form factors have the higher peak at a larger $q$, while the $3_2^-$ form factors show the lower peak at a smaller $q$. Similarly, one can see the difference also in the transition densities: narrower distributions of the $3_1^- \rightarrow 0_1^+$ transition densities and broader distributions with the outer tail of the $3_2^- \rightarrow 0_1^+$ transition densities because of the developed $^{16}$O+$\alpha$ cluster structure. One can say again that the $E3$ form factors and transition densities are sensitive to the state mixing between the $K^\pi = 2^-$ and $K^\pi = 0^-$ bands. Detailed discussions of its effect are given in Sec. [V].
tions. For the $4^+_1$ cross sections, the MCC+AMD result seems better than the MCC+CM result. For the $1^+_1$ and $3^+_2$ cross sections, there is no data for individual states at $E_\alpha = 104$ MeV, but the cross sections at $E_\alpha = 5.7$ MeV were reported by the $E_\alpha = 104$ MeV experiment in Ref. [90]. The data may contain the $1^+_1 (5.79$ MeV) and $3^+_1 (5.62$ MeV) contributions, but they can not be described by a simple sum of the calculated $1^+_1$ and $3^+_1$ cross sections of the present calculations. The $E_\alpha = 386$ MeV data of the $3^+_2$ cross sections are somewhat overestimated by the MCC+AMD calculation, in particular, at the second peak. In comparison of the MCC+AMD (red solid lines) and DWBA+AMD (blue dotted lines) calculations for $\alpha$ scattering, one can see non-negligible CC effect, in particular, at $E_\alpha = 104$ MeV, but the CC effect becomes weaker at $E_\alpha = 386$ MeV.

V. DISCUSSION

As discussed in previous sections, the structure calculation of AMD-ls34 with the modified spin-orbit strength suggests possible state mixing between the $K^\pi = 2^-$ and $K^\pi = 0^-$ bands in the $3^+_1$ and $3^+_2$ states of $^{20}\text{Ne}$. Let us remind that the default AMD calculation gives almost no state mixing and obtains the theoretical value of $B(E3;3^+_1 \rightarrow 0^+_1) = 53 e^2fm^4$ much smaller than the experimental value of $260 \pm 90 e^2fm^4$. In the AMD-ls34 result, the $K^\pi = 2^-$ band comes down to the lower energy than the $K^\pi = 0^-$ band consistently with the experimental energy spectra, and the state mixing occurs between the $3^+_1 (K^\pi = 2^-)$ and $3^+_2 (K^\pi = 0^-)$ states. As a consequence of mixing of the $K^\pi = 0^-_1$ cluster component in the $3^+_1 (K^\pi = 2^-)$ state, the theoretical $B(E3;3^+_1 \rightarrow 0^+_1)$ value is enhanced to be $B(E3;3^+_1 \rightarrow 0^+_1) = 155 e^2fm^4$ being in better agreement with the experimental value.

This state mixing between the $3^+_1$ and $3^+_2$ states affects the $E3$ form factors and transition densities. The AMD (red solid lines) and AMD-ls34 (blue dotted lines) results for the form factors are compared in Figs. [c] and (f), and those for the transition densities are compared in Fig. [b]. In these figures, the $3^+_1$ form factors and transition densities are renormalized with $f^{\alpha\alpha}$ for AMD and $f^{\alpha\alpha} = 1.30$ for AMD-ls34 so as to fit the data of $B(E3;3^+_1 \rightarrow 0^+_1)$. Namely, the renormalized $3^+_1$ transition densities of the two calculations (AMD and AMD-ls34) in Fig. [b] give the same value of $B(E3;3^+_1 \rightarrow 0^+_1) = 260 e^2fm^4$. Nevertheless, behaviors of the transition densities are different between the AMD and AMD-ls34 results. For the $3^+_1$ transition densities (Figs. [a] and (b)), AMD-ls34 gives a lower peak amplitude in the inner region ($r = 2-3$ fm) and a longer tail in the outer region ($r = 5$ fm) because of the mixing of the $K^\pi = 0^-_1$ cluster component. As a result, in the $3^+_1$ form factors of AMD-ls34, the peak amplitude gets smaller and the peak position shifts to a smaller $q$ (see the blue dotted line of Fig. [b]). Also the $3^+_2$ transition densities are strongly affected by the state mixing as shown in Fig. [c]. Because of the destructive mixing of the $K^\pi = 2^-$ component, inner amplitudes in the $r < 3$ fm region are suppressed and the outer peak around $r = 3-4$ fm gets smaller and shifts outwards in AMD-ls34 (blue dotted lines) than in AMD (red solide lines).

The mixing of the $K^\pi = 2^-$ and $K^\pi = 0^-$ also affects the $3^+_1$ and $3^+_2$ cross sections of proton and $\alpha$ inelastic scattering via the transition densities. In Fig. [b] the $3^+_1$ and $3^+_2$ cross sections calculated with AMD and AMD-ls34, and experimental data are compared. For the $(p,p')$ cross sections at $E_p = 25$ and $35$ MeV, the AMD-ls34 calculation obtains smaller cross sections of the $3^+_1$ and $3^+_2$ states than the original AMD result. In particular, the suppression at the second peak of the $3^+_1$ cross sections is remarkable and shows a better agreement with the $3^+_1$ data at $E_p = 25$ MeV. The $3^+_2$ cross sections are suppressed in the whole region of angles. As a result, the agreement with the $3^+_2$ data is improved at the first peak but gets somewhat worse at the second peak.

For $\alpha$ scattering to the $3^+_1$ state, peak positions shift to forward angles in the AMD-ls34 result probing the longer tail of the transition densities, which is caused by mixing of the $K^\pi = 0^-_1$ cluster component. Compared to the experimental $3^+_1$ cross sections at $E_\alpha = 386$ MeV, a good agreement is obtained by AMD-ls34. This result may support significant mixing of the $K^\pi = 0^-_1$ cluster component in the $3^+_1 (K^\pi = 2^-)$ state. For the $(\alpha,\alpha')$ cross sections at $E_\alpha = 104$ MeV, the data observed for $5.7$ MeV are not enough of high quality to discuss detailed features of the $3^+_1$ state because they contain large uncertainty from the $1^+_1$ contribution. As for the $3^+_2$ cross sections, the AMD-ls34 result predicts smaller cross sections than the AMD result because of the destructive mixing of the $K^\pi = 2^-$ component in the $3^+_2 (K^\pi = 0^-_1)$ state.

In the present analysis with AMD and AMD-ls34, we can say that possible mixing of the $K^\pi = 0^-_1$ cluster component in the $3^+_1$ state can be probed by proton and $\alpha$ cross sections through the transition densities. The better agreements of the AMD-ls34 result with the $(p,p')$ data at $E_p = 25$ MeV and $(\alpha,\alpha')$ data at $E_\alpha = 386$ MeV supports the significant outer tail of the $3^+_1$ transition densities and favors the state mixing case. For the $3^+_2$ state, experimental data are not enough to draw an answer to the state mixing in the $3^+_2$ state.

VI. SUMMARY

The structure and transition properties of the $K^\pi = 0^-_1$, $K^\pi = 2^-$, and $K^\pi = 0^-_2$ bands of $^{20}\text{Ne}$ were investigated with the microscopic structure and reaction calculations via proton and $\alpha$ scattering off $^{20}\text{Ne}$.

In the structure calculation of $^{20}\text{Ne}$ with AMD, $^{16}\text{O}+\alpha$ cluster structures were obtained in the parity-doublet $K^\pi = 0^-_1$ and $K^\pi = 0^-_2$ bands, and the $^{12}\text{C}+2\alpha$-like structure was obtained in the $K^\pi = 2^-_1$ band. The AMD calculation reproduced the experimental $B(E2)$ of
in-band transitions. It also described the experimental form factors of the $0^+_1$, $2^+_7$, and $4^+_7$ states.

The MCC calculations with the Melbourne $g$-matrix $NN$ interaction were performed for proton and $\alpha$ scattering off $^{20}$Ne using the AMD densities of $^{20}$Ne. The MCC calculations reasonably reproduced the observed cross sections of proton scattering at $E_p = 25$–$35$ MeV and $\alpha$ scattering at $E_\alpha = 104$–$386$ MeV. Transition properties from the ground to excited states were discussed via the reaction analyses of proton and $\alpha$ inelastic processes.

The mixing of the $K^\pi = 2^-$ and $K^\pi = 0^+_1$ bands in the $3^-_1$ and $3^-_2$ states was investigated in the analyses of AMD (default) with almost no mixing and AMD-ls34 (a modified spin-orbit strength) with the state mixing. The former calculation (AMD) significantly underestimates the experimental $B(E3; 3^-_1 \rightarrow 0^+_1)$, while the latter (AMD-ls34) calculation obtains a better result for $B(E3; 3^-_1 \rightarrow 0^+_1)$ because the $E3$ transition strength is enhanced by mixing of the $K^\pi = 0^+_1$ cluster component. The state mixing of the $3^-_1 (K^\pi = 2^-)$ and $3^-_2 (K^\pi = 0^-_1)$ states also affects the $E3$ transition densities from the ground state, which can be probed by $(p,p')$ and $(\alpha,\alpha')$ cross sections, in principle. The detailed analysis of proton and $\alpha$ cross sections for the $3^-_1$ and $3^-_2$ states was performed by the MCC calculations with AMD and AMD-ls34. The observed $(p,p')$ data at $E_p = 25$ MeV and $(\alpha,\alpha')$ data at $E_\alpha = 386$ MeV seems to support the mixing of the $K^\pi = 0^+_1$ cluster component in the $3^-_1 (K^\pi = 2^-)$ state.

It should be commented that applicability of the present MCC approach with the Melbourne $g$-matrix $NN$ interaction for low-energy proton scattering in the $E_p \lesssim 30$ MeV range has not been well examined yet. In order to clarify the properties of the $3^-_1$ and $3^-_2$ states, further detailed data of proton and $\alpha$ scattering at various energies are needed.

FIG. 6: Cross sections of proton elastic and inelastic scattering off $^{20}\text{Ne}$ at incident energies of $E_p = 25$, 30, and 35 MeV calculated with MCC+AMD (red solid lines), DWBA+AMD (blue dotted lines), and MCC+CM (green dashed lines), which are labeled as AMD, DWBA, and CM, respectively. Experiment data are cross sections at $E_p = 24.5$ MeV [26, 28], 30 MeV [28], and 35 MeV [59].
FIG. 7: Cross sections of $\alpha$ elastic and inelastic scattering off $^{20}$Ne at incident energies of $E_\alpha = 104, 146,$ and $386$ MeV calculated with MCC+AMD (red solid lines), DWBA+AMD (blue dotted lines), and MCC+CM (green dashed lines), which are labeled as AMD, DWBA, and CM, respectively. Experiment data are cross sections at $E_\alpha = 104$ MeV [30], and $146$ MeV [60], and $386$ MeV [31]. The $E_\alpha = 386$ MeV data from Ref. [31] are multiplied by a factor of two. The $(\alpha,\alpha')$ data at $E_\alpha = 104$ MeV in the panels (d) and (e) are the cross sections observed for $E_x = 5.7$ MeV and may contain $1_1^1 (5.79$ MeV) and $3_1^1 (5.62$ MeV) contributions.
FIG. 8: Transition densities from the ground to $3^{-}$ states obtained with AMD (default) and AMD-ls34 (modified spin-orbit strength). (a) transition densities to the $3^{-}_1$ state, (b) those but $r^2$-weighted, (b) transition densities to the $3^{-}_2$ state. Transition densities to the $3^{-}_1$ state in (a) and (b) are are renormalized by $f_{tr} = 2.22$ for AMD and 1.30 for AMD-ls34.
FIG. 9: Cross sections of proton and $\alpha$ inelastic scattering calculated with MCC using the AMD (default) and AMD-ls34 (modified spin-orbit strength) densities, and the experimental cross sections. The $(p,p')$ cross sections at $E_p = 25$ and 35 MeV to the (a) $3^-_1$ and (b) $3^-_2$ states and the $(\alpha,\alpha')$ cross sections at $E_\alpha = 146$, and 386 MeV to the (c) $3^-_1$ and (d) $3^-_2$ states. The $(p,p')$ data at $E_p = 24.5$ MeV [28] and $(\alpha,\alpha')$ data at $E_\alpha = 104$ MeV [30] and 386 MeV [31] are also shown. The $(\alpha,\alpha')$ data at 386 MeV of Ref. [31] are multiplied by a factor of two. The $(\alpha,\alpha')$ data at $E_\alpha = 104$ MeV in the panel (c) are not cross sections for an individual state but may contain $1^-_1$ and $3^-_1$ contributions around 5.7 MeV.
