(Received 23 May 2013; accepted 14 June 2013)

A polymerizable room temperature ionic liquid (RTIL), 2-acrylamido-2-methyl-1-propane sulfonic acid (AMPS) – triethylamine (TEA), was synthesized by neutralization of AMPS with TEA in acetone followed by evaporation of the solvent under a reduced pressure at room temperature. The RTIL was characterized with Fourier transform infrared spectroscopy, differential scanning calorimetry (DSC), and \textsuperscript{1}H NMR. Co-polymeric gels of the RTIL with acrylamide (AAm) were prepared by aqueous solution polymerization using N,N\textsuperscript{'},methylenebisacrylamide as a crosslinker, and ammonium persulfate as an initiator. Superabsorbency of the gels in aqueous and a series of organic liquids was investigated gravimetrically. DSC data showed that the glass transition temperature of AMPS – TEA was \(-59.4\) °C. Poly (AMPS – TEA-co-AAm) gels exhibited superabsorbency in both water and a series of organic solvents. The mechanism for swelling in aqueous and organic media of the gels was critically discussed.

Keywords: 2-acrylamido-2-methyl-1-propane sulfonic acid (AMPS); triethylamine (TEA); room temperature ionic liquid (RTIL); acrylamide; superabsorbency

Introduction

Being melting salts at room temperature and completely composed of discrete cations and anions, room temperature ionic liquids (RTILs) have received much interest due to their unique properties such as negligible vapor pressure, thermal stability, chemical stability and nonflammability, relatively high ionic conductivity and wide potential window.[1–13] Based on such properties, a large amount of applications, such as solvent in synthesis, catalysis, biocatalysis and in electrochemistry, have been explored.[14–18] Recently, using of RTILs to form polymeric materials was found to take an enabling role in some fields of polymer chemistry and material science.[19–23] This includes immobilizing RTILs in solid devices and polymerizing RTILs with unsaturated bonds to give a special type of polyelectrolytes that carry an RTIL species in each of the repeating units.[24–34] In this work, a polymerizable RTIL, 2-acrylamido-2-methyl-1-propane sulfonic acid (AMPS), and triethylamine (TEA) was synthesized by neutralization of AMPS and TEA, the co-polymeric gels of the RTIL with acrylamide (AAm) was synthesized, and it was found that the gels showed superabsorbency for both water and a variety of organic solvents. The molecular structures of the chemicals used in this work are shown in Scheme 1.

Experimental

Materials

AMPS, Sigma–Aldrich; AAm, N,N\textsuperscript{'},methylenebisacrylamide (MBAm), ammonium persulfate (APS), TEA, acetone, they were analytical reagent grade and used as received without further purification.

Synthesis of AMPS – TEA

About 20 g acetone was added to a flask, then added 5 g AMPS, and 2.50 g TEA was added to the flask in drops under stirring. When the powder in the solution disappeared and the solution turned clear, stopped stirring and evaporated the solvent under a reduced pressure at room temperature, to give a transparent and pale yellow liquid.
Characterizations of AMPS – TEA
Differential scanning calorimetry (DSC) analysis was preformed for AMPS – TEA with Mettler Teledo DSC1. The measurement conditions were with a scanning rate of 10 °C/min and nitrogen gas flow rate of 50 ml/min. Fourier transform infrared spectroscopy (FT-IR) spectrophotometer (Bruker Vector) was used to characterize AMPS – TEA as well. $^1$H NMR (nuclear magnetic resonance) characterization for AMPS – TEA was performed with Bruker AV400 using CDCl3 as a solvent.

Synthesis of poly(AMPS – TEA-co-AAm) gels
AMPS – TEA, AAm, MBAm, and APS were dissolved in water successively to give reaction solution. The dosage of APS was 0.1% gross weight of the reaction solution. The total monomers concentration of the reaction solution was 40% by weight. The dosage of MBAm and the proportion of AMPS – TEA (calculated by AMPS) and AAm varied to give hydrogels with different compositions.

The reaction solution was heated in a water bath with 50 °C for 24 h. The resulted hydrogels was immersed in distilled water for 7 days and the water was changed every 24 h to remove water-soluble materials, followed by drying the hydrogels in an oven at 105 °C to give xerogel.

Swelling measurements of poly(AMPS – TEA-co-AAm) gels
The xerogel of poly(AMPS – TEA-co-AAm) was immersed in water and a variety of organic solvents to test the swelling characteristics. The equilibrium swelling behavior of the samples was measured by a gravimetric method. The samples were made to swell with distilled water and various organic solvents at room temperature until the swelling equilibrium were reached, followed by being removed and blotted with filter paper to remove the overloaded liquids on the surface, and weighed. The equilibrium swelling ratio was defined as follows:

$$Q = \frac{W_w - W_d}{W_d}$$

where $W_w$ was weight of the swollen gels and $W_d$ was weight of the xerogel.

Results and discussion

Synthesis of AMPS – TEA
In the present work, AMPS – TEA was prepared by neutralizing AMPS with TEA in acetone followed by evaporation of the solvent under a reduced pressure at room temperature; the reaction can be expressed by Scheme 2. It was found that the resulted salt was transparent liquids with pale yellow at room temperature, DSC showed that the glass transition temperature was about −59.4 °C, as shown in Figure 1.

Characterization of AMPS – TEA
The resulted salt was characterized with FT-IR and $^1$H NMR. The FT-IR spectrum and the $^1$H NMR spectrum of the salt were shown in Figures 2 and 3, respectively. In Figure 2, characteristic peaks of $–\text{SO}_3$ were shown. Peak 620 cm$^{-1}$ is absorption of the C–S bond, peak 1040 cm$^{-1}$ is absorption of the S–O bond, and peak 1200 cm$^{-1}$ was the absorption of $–\text{S}=\text{O}$. Other characteristic peaks of the salt are also shown. Peak 1640 cm$^{-1}$ is absorption of the $–\text{C}=\text{O}$ bond, and peak 1560 cm$^{-1}$ is absorption of the $–\text{C}–\text{N}$ bond. Combining with the values of chemical shift of the resulted salt shown in Figure 3, the structure of the resulted salt can be decided, as shown in Figure 4.

Synthesis of poly(AMPS – TEA-co-AAm) gels
Poly(AMPS – TEA-co-AAm) gels were prepared by free radical aqueous solution co-polymerization of AMPS – TEA, MBAm, and AAm. The resulted poly (AMPS – TEA-co-AAm) was transparent and glassy hydrogels. The formation of the crosslinked networks can be expressed by Scheme 3.

Swelling of poly(AMPS – TEA-co-AAm) gels in organic solvents

The swelling characteristic of poly(AMPS – TEA-co-AAm) gels in water and a variety of organic solvents was investigated. It showed poly(AMPS – TEA-co-AAm) gels can not only swell in water, but also in a variety of polar and non-polar organic solvents. The superabsorbency of the poly (AMPS – TEA-co-AAm) gels with the composition of AAm 30%, AMPS 70%, and MBAm 0.20% (all of them calculated by the gross weight of AAm and AMPS) was investigated. A series of most conventional alcohols, chlorinated methanes, amines, and acetone, acetonitril, dimethylsulfoxide were examined because these organic solvents are of significant importance commercially in wide varieties of applications. Surveying and studying new materials to highly imbibe these organic solvents will be of great potential importance. The dielectric constant (\(\varepsilon\)) and the absorbency by the poly(AMPS – TEA-co-AAm) gels of these solvents are shown in Table 1.

It was found that the poly(AMPS – TEA-co-AAm) gels showed superabsorbency for both water and a variety of organic solvents, irrespective of their polarity (dielectric constant). It has been widely known that super absorbent polymers swell and absorb water up to several hundred times their dried weights and have become ubiquitous and indispensable materials in many applications – their high swelling abilities in water originate from the electrostatic repulsion between the ions fixed on the polymer chains and osmotic pressure induced by freely mobile counterions in the networks of the polyelectrolyte gels – charged polymers with associated counterions, while such polyelectrolyte gels hardly swell in organic liquids as a result of aggregation of ion pairs. [35–39] In this case, dissociation ability of the ionic partners on the polymer chains plays an important role during swelling of polyelectrolyte gels in a solvent. Rationally by this principle, the incorporation of polymerizable RTILs that are melting salts at room temperature completely composed of discrete cations and anions into the chains of polyelectrolyte gels ought to inhibit aggregation of the ionic partners both in water and in organic liquids, which in turn would allow RTILs-based gels to behave as superabsorbent gels irrespective of their liquid environment.

In addition, it has been discussed that the swelling of a crosslinked neutral polymer without any charges on the backbones in a solvent is caused by the imbalance between the repulsive forces among the polymer chains and the contractile forces due to stretching of elastically active networked structures.[40,41] Thus, both the compatibility of the polymer chains with the solvents and the crosslinking density of the networked structures play a key role in the swelling and collapsing of neutral polymer gels. In the same way, for polyelectrolyte gels, poor solvent compatibility with the backbones will not allow penetration of the solvent molecules into the polymer networks, while poor solvent compatibility with the counterions will not allow the dissociation of the ionic partners. As a result, the polymer gels collapses, even though the ion pairs would be easily dissociated. Alexander-Katz and Leibler [42] have been theoretically discussing the effect of counterion solubility, instead of backbone solubility, on the stability of polyelectrolyte solutions. Therefore, it was thought that the solubility of counterion as well as the backbone of poly(AMPS – TEA-co-AAm) gels resulted in the superabsorbency for both water and some organic solvents.

### Table 1. The dielectric constant (\(\varepsilon\)) and the absorbency by the poly(AMPS – TEA-co-AAm) gels of the solvents.

| Solvent            | Dielectric constant (\(\varepsilon\)) | Absorbency (g/g) |
|--------------------|--------------------------------------|------------------|
| Hexane             | 1.8865                               | 0 (Collapse)     |
| Carbon tetrachloride | 2.24                                 | 0 (Collapse)     |
| Butylamine         | 4.71                                 | 35               |
| Chloroform         | 4.81                                 | 0 (Collapse)     |
| Dichloromethane    | 8.93                                 | 0 (Collapse)     |

| Water              | 80.1                                 | 218              |

Influence of AAm content in the gels on the swelling characteristic

Various poly(AMPS – TEA-co-AAm) gels with different compositions were prepared by changing MBAm and AAm feeding during preparation of the reaction solution. It was found that the superabsorbency of poly(AMPS – TEA-co-AAm) gels were seriously influenced by the composition. The effect of AAm feeding on the superabsorbency is shown in Figure 5. It was found that without AAm feeding, crosslinked homo-polymer of AMPS – TEA was not transparent and glassy gel but muddy mixture without any strength, it did not absorb any solvent. Crosslinked poly(AMPS – TEA-co-AAm) also did not absorb any solvent as the AAm feeding was less than 15% (calculated by the gross weight of AMPS and AAm). Increased AAm feeding in the range of 15–30 wt.% (for
water, methanol, and ethanol), 40 wt.% (for butylamine and 1-methyl-2-pyrrolidone) or 45 wt.% (for dimethylsulfoxide), the absorbency of the gels increased accordingly; while the absorbency of the gels decreased as the AAm feeding continued to increase. The gels did not swell any more as the AAm feeding was more than 60 wt.% (for butylamine), 70 wt.% (for 1-methyl-2-pyrrolidone), 90 wt.% (for dimethylsulfoxide), or 95 wt.% (for methanol and ethanol).

**Influence of MBAm content in the gels on the swelling characteristic**

The effect of MBAm feeding on the superabsorbency is shown in Figure 6. In the range of 0.05–0.20 wt.%, the absorbency to water, methanol, and ethanol of poly(AMPS–TEA-co-AAm) gels increased with the increase in the dosage of MBAm, while the absorbency decreased with the increase in the dosage of MBAm in the range of 0.20–0.30 wt.%. It was clear that a higher MBAm feeding induced an increased crosslinking density which resulted in a decreased absorbency; reducing the amount of crosslinker increased the swelling ability, but stable networks cannot form if the crosslinking density was too low.

**Conclusion**

A polymerizable RTIL, AMPS–TEA, was synthesized and characterized. DSC showed that the glass transition temperature of AMPS–TEA was about –59.4°C. Co-polymeric gels of AMPS–TEA with AAm were synthesized. Poly(AMPS–TEA-co-AAm) gels were transparent and glassy. The gels can swell in both water and a variety of organic solvents, irrespective of their polarity. The swelling mechanism of poly(AMPS–TEA-co-AAm) gels lies in the dissociation ability of the ionic partners on the polymer chains as a result of incorporation of AMPS–TEA which is completely composed of discrete cations and anions into main chains of the polyelectrolyte gels, as well as the solubility of both counterion and the backbone in the solvents.
