ABSTRACT

Three-nucleon (3N) forces are an indispensable ingredient for accurate few-body and many-body nuclear structure and reaction theory calculations. While the direct implementation of chiral 3N forces can be technically very challenging, a simpler approach is given by employing instead a medium-dependent NN interaction $V_{\text{med}}$ that reflects the physics of three-body forces at the two-body normal-ordered approximation. We review the derivation and construction of $V_{\text{med}}$ from the chiral 3N interaction at next-to-next-to-leading order (N2LO), consisting of a long-range $2\pi$-exchange term, a mid-range $1\pi$-exchange component and a short-range contact-term. Several applications of $V_{\text{med}}$ to the equation of state of cold nuclear and neutron matter, the nucleon single-particle potential in nuclear matter, and the nuclear quasiparticle interaction are discussed. We also explore differences in using local vs. nonlocal regulating functions on 3N forces and make direct comparisons to exact results at low order in perturbation theory expansions for the equation of state and single-particle potential. We end with a discussion and numerical calculation of the in-medium NN potential $V_{\text{med}}$ from the next-to-next-to-next-to-leading order (N3LO) chiral 3N force, which consists of a series of long-range and short-range terms.

Keywords: Chiral effective field theory, three-body forces, nuclear matter, equation of state, nuclear reaction theory

1 INTRODUCTION

Three-nucleon forces are essential to any microscopic description of nuclear many-body systems, from the structure and reactions of finite nuclei [1, 2, 3, 4] to the equation of state and transport properties of dense matter encountered in core-collapse supernovae and neutron stars [2, 5, 6, 7, 8, 9, 10, 11, 12, 13]. Three-body forces have been shown to dramatically improve the saturation properties of nuclear matter [6, 7, 14], though there are still large uncertainties compared to the empirical saturation energy and density. Three-nucleon forces also now being routinely implemented in a number of ab initio many-body methods such as the no-core shell model [15], coupled-cluster theory [16, 17], self-consistent Green’s function theory [18], the similarity renormalization group [19, 20], and quantum Monte Carlo [3] to study nuclear ground-state and excited states up to medium-mass nuclei. In particular, three-body forces have been shown to be especially relevant for understanding the properties of neutron-rich nuclei out to the drip line [16, 18, 21, 22].
Implementing chiral three-body forces

Figure 1. Diagrammatic contributions to the chiral three-nucleon force at next-to-next-to-leading order (N2LO) in the chiral expansion.

In the past, it has been challenging [5] to obtain nuclear two- and three-body forces that simultaneously fit well the properties of finite nuclei and nuclear matter, but in recent years, much progress has been achieved within the framework of chiral effective field theory [23, 24, 25, 26, 27] to construct three-body forces consistent with the employed two-body force, all within a systematic power series expansion involving the ratio of the physical scale $Q$ to the chiral symmetry breaking scale $\Lambda_{\chi} \sim 1$ GeV. In chiral effective field theory with explicit nucleon and pion degrees of freedom only, three-nucleon forces appear first at third order in the chiral expansion $(Q/\Lambda_{\chi})^3$, or next-to-next-to-leading (N2LO) order. These leading contributions to the chiral three-nucleon force (3NF) are now routinely employed in nuclear structure and reaction theory calculations, but many-body contributions at N3LO [28, 29, 30, 31] are expected to be important.

In the present work, we will review how to implement three-nucleon forces via medium-dependent two-body interactions [6, 7, 32] in nuclear many-body calculations of the equation of state, single-particle potential, and quasiparticle interaction. We will show that this approach provides an excellent approximation at first order in many-body perturbation theory by comparing to exact results from three-body forces. At higher orders in perturbation theory, the use of medium-dependent NN interactions fail to reproduce all topologies, however, residual three-body interactions have been shown [33] to give relatively small contributions ($\sim 1$ MeV) to the nuclear equation of state at saturation density up to second order in perturbation theory. We also consider several commonly used high-momentum regulating functions for three-body forces and study their impact on the density-dependent interaction $V_{\text{med}}$. In particular, we find that local regulators introduce large artifacts compared to nonlocal regulators when the same value of the cutoff scale $\Lambda$ is used in both cases.

2 FROM THREE-BODY FORCES TO MEDIUM-DEPENDENT TWO-BODY FORCES

2.1 Chiral three-body force at next-to-next-to-leading order

The nuclear Hamiltonian can generically be written in the form

$$H = \sum_i \frac{\vec{p}_i^2}{2M} + \frac{1}{2} \sum_{ij} V_{ij} + \frac{1}{6} \sum_{ijk} V_{ijk} + \cdots,$$

where $\vec{p}_i$ is the momentum of nucleon $i$, $V_{ij}$ represents the two-body interaction between particles $i$ and $j$, and $V_{ijk}$ represents the three-body interaction between particles $i, j, k$. Three-body forces emerge first at N2LO in the chiral expansion and contain three different topologies represented diagrammatically in Fig. 1. The two-pion-exchange three-body force, Fig. 1(a), contains terms proportional to the low-energy
constants $c_1$, $c_3$, and $c_4$:

$$V_{3N}^{(2\pi)} = \sum_{i\neq j\neq k} \frac{g_A^2}{8 f_{\pi}^4} \frac{\bar{\sigma}_i \cdot \vec{q}_i \bar{\sigma}_j \cdot \vec{q}_j}{(\vec{q}_i^2 + m_{\pi}^2)(\vec{q}_j^2 + m_{\pi}^2)} F_{ijk}^{\alpha\beta} \tau_i^\alpha \tau_j^{\beta},$$

(2)

where $g_A = 1.29$ is the axial coupling constant, $m_{\pi} = 138$ MeV is the average pion mass, $f_{\pi} = 92.2$ MeV is the pion decay constant, $\vec{q}_i = \vec{k}_i^j - \vec{k}_i$ is the change in momentum of nucleon $i$ (i.e., the momentum transfer), and the isospin tensor $F_{ijk}^{\alpha\beta}$ is defined by

$$F_{ijk}^{\alpha\beta} = \delta^{\alpha\beta} (-4 c_1 m_{\pi}^2 + 2 c_3 \vec{q}_i \cdot \vec{q}_j) + c_4 e^{\alpha\beta\gamma\tau_k} \bar{\sigma}_k \cdot (\vec{q}_i \times \vec{q}_j).$$

(3)

The three low-energy constants $c_1$, $c_3$, and $c_4$ can be fitted to empirical pion-nucleon [34, 35] or nucleon-nucleon [36, 37] scattering data.

The one-pion exchange term, Fig. 1(b), proportional to the low-energy constant $c_D$ has the form

$$V_{3N}^{(1\pi)} = -\sum_{i\neq j\neq k} \frac{g_{ACD}}{8 f_{\pi}^4 \Lambda_X} \frac{\bar{\sigma}_j \cdot \vec{q}_j}{\vec{q}_j^2 + m_{\pi}^2} \bar{\sigma}_i \cdot \vec{q}_i \tau_i \cdot \tau_j,$$

(4)

where the high-momentum scale is typically taken as $\Lambda_X = 700$ MeV. The three-nucleon contact force, Fig. 1(c), proportional to $c_E$ is written:

$$V_{3N}^{(ct)} = \sum_{i\neq j\neq k} \frac{c_E}{2 f_{\pi}^4 \Lambda_X} \tau_i \cdot \tau_j.$$

(5)

There are several different experimental observables commonly used for fitting the low-energy constants $c_D$ and $c_E$. Most approaches fit the binding energies of $A = 3$ nuclei together with one of the following observables: (a) the neutron-deuteron doublet scattering length [38, 39], (b) the radius of $^4$He [40], (d) the properties of light and medium-mass nuclei [41, 42], and (d) the triton lifetime [43, 44].

Since the three-nucleon force $V_{3N}$ is symmetric under the interchange of particle labels, there are only three independent terms from the $i, j, k$ permutations, which allows us to write $V_{3N} = W_1 + W_2 + W_3$. For instance, $W_1^{(ct)} = \frac{c_E}{2 f_{\pi}^4 \Lambda_X} \tau_2 \cdot \tau_3$. The antisymmetrized three-body interaction $\bar{V}_{3N}$ can be written in terms of two-body antisymmetrization operators $P_{ij}$ as follows:

$$\bar{V}_{3N} = (1 - P_{12})(1 - P_{13} - P_{23})V_{3N},$$

(6)

where

$$P_{ij} = \left(\frac{1 + \bar{\sigma}_i \cdot \bar{\sigma}_j}{2}\right) \left(\frac{1 + \tau_i \cdot \tau_j}{2}\right), \quad \vec{k}_i \leftrightarrow \vec{k}_j.$$  

(7)

**2.2 Density-dependent NN interaction at order N2LO**

In second quantization, a three-body force $V_{3N}$ can be written as

$$V_{3N} = \frac{1}{36} \sum_{123456} \langle 123 | \bar{V}_{3N} | 456 \rangle a_1^\dagger a_2^\dagger a_3^\dagger a_6 a_5 a_4$$

(8)
where $\bar{V}_3^{N}$ denotes the antisymmetrized three-body matrix element, and $a_i^\dagger$ ($a_i$) are the usual creation (annihilation) operators associated with state $|i\rangle$. A medium-dependent two-body interaction can then be constructed by normal ordering the three-body force with respect to a convenient reference state, such as the ground state of the noninteracting many-body system, rather than the true vacuum as in Eq. (8). Normal ordering with respect to the noninteracting ground state then produces a three-body force of the form

$$V_{3N} = \frac{1}{6} \sum_{ijk} \langle ijk | \bar{V}_3^{N} | ijk \rangle + \frac{1}{2} \sum_{ij14} \langle ij1 | \bar{V}_3^{N} | ij4 \rangle : a_1^\dagger a_4 \cdot + \frac{1}{4} \sum_{i1245} \langle i12 | \bar{V}_3^{N} | i45 \rangle : a_1^\dagger a_2^\dagger a_5 a_4 :$$

$$+ \frac{1}{36} \sum_{123456} \langle 123 | \bar{V}_3^{N} | 456 \rangle : a_1^\dagger a_2^\dagger a_3^\dagger a_6 a_5 a_4 :,$$

where $: \hat{O} :$ denotes normal ordering of operator $\hat{O}$. In practice the construction of the medium-dependent two-body force

$$\frac{1}{4} \sum_{i1245} \langle i12 | \bar{V}_3^{N} | i45 \rangle : a_1^\dagger a_2^\dagger a_5 a_4 :$$

then amounts to summing the third particle over the filled states in the noninteracting Fermi sea, involving spin and isospin summations as well as momentum integration:

$$\bar{V}_{\text{med}} = \sum_{s1t3} \int \frac{d^3k_3}{(2\pi)^3} \theta(k_f - k_3)(1 - P_{13} - P_{23}) V_{3N},$$

where $k_f$ is the Fermi momentum and we have absorbed the particle exchange operator $(1 - P_{12})$ into the definition of the antisymmetrized medium-dependent NN interaction $\bar{V}_{\text{med}}$. In general, there are nine different diagrams that need to be evaluated independently: $(1 - P_{13} - P_{23})(W_1 + W_2 + W_3)$, which correspond to different closings of one incoming and outgoing particle line.

As a simple example, we compute the density-dependent NN interaction arising from the three-body contact term at N2LO shown diagrammatically in Fig. 2(f). We begin by evaluating the spin and isospin
which gives a final result of

$$p = 0$$

where we have used the well known properties of Pauli matrices: \( \text{Tr} \sigma = 0, \text{Tr} \mathbb{1} = 2, \text{Tr}_3(\vec{r}_i \cdot \vec{r}_3)(\vec{r}_j \cdot \vec{r}_5) = 2\vec{r}_i \cdot \vec{r}_j, \) and \( \vec{r}_i \cdot \vec{r}_i = 3. \) The integration over filled momentum states is trivial:

$$\int \frac{d^3 k_3}{(2\pi)^3} \theta(k_f - k_3) \frac{c_E}{f_\chi^2} = \frac{1}{2\pi^2} \frac{k_f^3}{3} \frac{c_E}{f_\chi^2},$$

which gives a final result of

$$V^{(ct)}_{\text{med}} = -\frac{c_E k_f^3}{\pi^2 f_\chi^2}.$$  \hspace{1cm} (14)

This particularly simple three-body contact interaction gives rise to a momentum-independent effective two-body interaction. For the more complicated \(1\pi\) - and \(2\pi\)-exchange topologies, it is convenient to consider the on-shell scattering (\(|\vec{p}| = |\vec{p}'|\)) of two nucleons in the center-of-mass frame: \(N_1(\vec{p}) + N_2(-\vec{p}) \rightarrow N_1(\vec{p}'') + N_2(\vec{p}').\) This assumption results in a medium-dependent 2N interaction with the same isospin and spin structures as the free-space 2N potential, which allows for a simple decomposition of \(V_{\text{med}}\) into partial-wave matrix elements as we show in Section 4.1. In the more general case \(N_1(\vec{p}_1) + N_2(\vec{p}_2) \rightarrow N_1(\vec{p}_3) + N_2(\vec{p}_4),\) the in-medium 2N interaction will contain operator structures depending on the center-of-mass momentum \(\vec{P} = \vec{p}_1 + \vec{p}_2 = \vec{p}_3 + \vec{p}_4.\) Such contributions have been shown to be small in practice [45]. In the applications discussed below, higher-order perturbative contributions to the ground state energy and single-particle energies involve also off-shell matrix elements of the interaction \(|\vec{p}|V|\vec{p}'|\), where \(|\vec{p}| \neq |\vec{p}'|\). In such cases we use the approximation \(p^2 \rightarrow \frac{1}{2}(p^2 + p'^2)\) in the formulas derived below. The resulting interaction can then be straightforwardly implemented into modern nuclear structure codes. We will explicitly test some of the approximations noted above by comparing exact results at low order in perturbation theory using the full 3-body force to the results using instead the medium-dependent 2N interaction.

Note that in the above derivation of the density-dependent 2N interaction associated with \(V^{(ct)}_{\text{med}}\), we have not applied a high-momentum regulator, which would be necessary to eliminate the components of the nuclear interaction that lie beyond the breakdown scale of the effective field theory. In the case of nucleon-nucleon potentials, the cutoff scale is typically chosen \(\Lambda \lesssim 700\) MeV, beyond which the introduction of a new dynamical degree of freedom (the \(\rho\) meson with mass \(m_\rho = 770\) MeV) would be required. On the other hand, in order to fit empirical nucleon-nucleon scattering phase shift data up to laboratory energies of \(E_{\text{lab}} = 350\) MeV, the cutoff is normally chosen \(\Lambda \gtrsim 414\) MeV (the relative
momentum in the center-of-mass frame corresponding to $E_{\text{lab}} = 350 \text{ MeV}$). In practice, it is found that relatively low values of the momentum-space cutoff $\Lambda \lesssim 500 \text{ MeV}$ lead to perturbative nucleon-nucleon potentials, which are suitable for a wide range of methods to solve the quantum many-body problem. Such low-cutoff potentials, however, exhibit larger artifacts in calculations of the density-dependent ground state energy of nuclear matter and single-particle potential as we will discuss explicitly below. While the choice of cutoff scale is well motivated, the regulating function can take various forms. Traditionally, an exponential regulator in the incoming and outgoing relative momenta is chosen:

$$ f(p', p) = \exp\left[-(p'/\Lambda)^{2n} - (p/\Lambda)^{2n}\right], $$

(15)

where $\vec{p} = \frac{1}{2}(\vec{p}_1 - \vec{p}_2)$ and $\vec{p}' = \frac{1}{2}(\vec{p}_3 - \vec{p}_4)$ for the general two-body scattering process $N(\vec{p}_1) + N(\vec{p}_2) \to N(\vec{p}_3) + N(\vec{p}_4)$, and $n$ is an integer chosen such that the regulator affects only high powers in the chiral expansion. More recently [27,46], the pion-exchange components of the nucleon-nucleon interaction have been regularized in coordinate space according to

$$ V_{\pi}(\vec{r}) \left[1 - e^{-r^2/R^2}\right], $$

(16)

where $0.8 \text{ fm} \leq R \leq 1.2 \text{ fm}$, while the contact terms in the nuclear potential were regularized according to Eq. (15) above. In previous calculations [47,48] of the medium-dependent 2N force $V_{\text{med}}$, we have imposed the nonlocal regulating function above only after the momentum-space integration over $k_3$ is performed. This choice led to simplified analytical expressions for the density-dependent NN interaction in cold nuclear matter. A three-body regulator that treats all particles symmetrically can be defined by [49]

$$ W_3 \longrightarrow W_3 F(q_1, q_2) = W_3 \exp\left[-(q_1/\Lambda)^4 - (q_2/\Lambda)^4\right], $$

(17)

where $\vec{q}_1 = \vec{p}'_1 - \vec{p}_1$ and $\vec{q}_2 = \vec{p}'_2 - \vec{p}_2$ are the momentum transfers for particles 1 and 2 in $W_3$. Analogous expressions hold for the contributions $W_1 \longrightarrow W_1 F(q_2, q_3)$ and $W_2 \longrightarrow W_2 F(q_1, q_3)$. This choice of regulating function leads to more complicated expressions for the density-dependent 2N interaction since now the regulator in general can involve the momentum $k_3$ over which we integrate. More importantly, the local regulator in Eq. (17) leads to much stronger cutoff artifacts for the same choice of scale ($\Lambda_{\text{loc}} = \Lambda_{\text{nonloc}}$) as we will demonstrate in the following. Additional discussion regarding the role of cutoff artifacts on nuclear many-body calculations can be found in Ref. [50].

To start, when we employ the local regulator in Eq. (17), we now find for the density-dependent NN interaction in isospin-symmetric nuclear matter:

$$ V_{\text{med}}^{(\text{ct})} = \frac{c F_{\pi}^4}{2\pi^2} \chi \left[\frac{4}{3} \int_{-1}^{1} dx \int_{0}^{k_f} dk \frac{k^3}{\Lambda} \cdot \tilde{F}(q^2, \Lambda) - 2 \tilde{F}(q^2, \Lambda) \tilde{\Gamma}_4(p) - 3 \tilde{\Gamma}_4'(p, q)\right], $$

(18)

where

$$ F(q^2, \Lambda) = e^{-q^4/\Lambda^4}, $$

(19)

$$ \tilde{\Gamma}_4(p) = \int_{0}^{k_f} dk \int_{-1}^{1} dx k^2 F(p^2 + k^2 + 2pkx, \Lambda), $$

(20)
\[
\Gamma_4'(p, q) = \int_{0}^{k_f} dk \int_{-1}^{1} dx \int_{0}^{2\pi} d\theta \frac{k^2}{2\pi} F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos\phi, \Lambda) \\
\times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} - qk\sqrt{1 - x^2}\cos\phi, \Lambda).
\] (21)

In the limit of large \( \Lambda \) we find that \( F(q^2, \Lambda) \to 1, \tilde{\Gamma}_4(p) \to \frac{2k^3}{3}, \) and \( \Gamma_4'(p, q) \to \frac{2k^3}{3} \). Thus, in this limit we clearly recover Eq. (14).

Previously, for the in-medium pion self-energy correction, Fig. 2(a), with no regulator we found

\[
V_{NN}^{\text{med},1} = g_A^2 k_f^3 3\pi f_\pi^4 \tilde{\tau}_1 \cdot \tilde{\tau}_2 \frac{\bar{q}_1 \cdot \bar{q}_2 \cdot \bar{q}}{(m_\pi^2 + q^2)^2} \left( 2c_1 m_\pi^2 + c_3 q^2 \right). \] (22)

With the local regulator in Eq. (17) we now find

\[
V_{NN}^{\text{med},1} = \frac{g_A^2 k_f^3}{3\pi f_\pi^4} \tilde{\tau}_1 \cdot \tilde{\tau}_2 \frac{\bar{q}_1 \cdot \bar{q}_2 \cdot \bar{q}}{(m_\pi^2 + q^2)^2} \left( 2c_1 m_\pi^2 + c_3 q^2 \right) F^2(q^2, \Lambda). \] (23)

Previously, for the Pauli-blocked vertex correction, Fig. 2(b), we found

\[
V_{NN}^{\text{med},2} = \frac{g_A^2}{8\pi f_\pi^4} \tilde{\tau}_1 \cdot \tilde{\tau}_2 \frac{\bar{q}_1 \cdot \bar{q}_2 \cdot \bar{q}}{m_\pi^2 + q^2} \left( -4c_1 m_\pi^2 \tilde{\Gamma}_0 + \tilde{\Gamma}_1 \right) \left( -c_3 + c_4 \right) \left( \tilde{\Gamma}_0 + 2\tilde{\Gamma}_1 + \tilde{\Gamma}_3 \right) + 4c_4 \left[ \frac{2k^3}{3} - m_\pi^2 \tilde{\Gamma}_0 \right]. \] (24)

When the local regulators are employed, we now find that the \( p \)-dependent auxiliary functions \( \Gamma_i \) must be replaced by

\[
\tilde{\Gamma}_0(p) = \int_{0}^{k_f} dk \int_{-1}^{1} dx \frac{k^2}{m_\pi^2 + p^2 + k^2 + 2pkx, \Lambda), \] (25)

\[
\tilde{\Gamma}_1(p) = \int_{0}^{k_f} dk \int_{-1}^{1} dx \frac{k^3 x / p}{m_\pi^2 + p^2 + k^2 + 2pkx, \Lambda), \] (26)

\[
\tilde{\Gamma}_2(p) = \int_{0}^{k_f} dk \int_{-1}^{1} dx \frac{k^4(1 - x^2)/2}{m_\pi^2 + p^2 + k^2 + 2pkx, \Lambda), \] (27)

\[
\tilde{\Gamma}_3(p) = \int_{0}^{k_f} dk \int_{-1}^{1} dx \frac{k^4(3x^2 - 1)/(2p^2)}{m_\pi^2 + p^2 + k^2 + 2pkx, \Lambda). \] (28)

where the unprimed versions of these functions in Eq. (24) can be obtained by setting \( \Lambda \to \infty \). In addition, the term \( 4c_4 \left[ \frac{2k^3}{3} \right] \) in \( V_{NN}^{\text{med},2} \) must be replaced with the quantity

\[
4c_4 \left[ \frac{2k^3}{3} \right] \rightarrow 4c_4 \int_{0}^{k_f} dk \int_{-1}^{1} dx k^2 F(p^2 + k^2 + 2pkx, \Lambda) \equiv 4c_4 \tilde{\Gamma}_4(p). \] (29)
Then the revised Pauli-blocked vertex correction has the form
\[ V_{NN}^{med,2} = \frac{g_A^2}{8\pi^2 f_F^2} \tilde{r}_1 \cdot \tilde{r}_2 \frac{\bar{q} \cdot \bar{q}}{m_n^2 + q^2} \left( -4c_1 m_n^2 [\tilde{\Gamma}_0 + \tilde{\Gamma}_1] - (c_3 + c_4)[q^2 (\tilde{\Gamma}_0 + 2\tilde{\Gamma}_1 + \tilde{\Gamma}_3) + 4\tilde{\Gamma}_2] + 4c_4 \left[ \tilde{\Gamma}_4 - m_n^2 \tilde{\Gamma}_0 \right] \right) F(q^2, \Lambda). \] (30)

Previously, we found for the Pauli-blocked two-pion-exchange interaction, Fig. 2c,
\[ V_{NN}^{med,3} = \frac{g_A^2}{16\pi^2 f_F^2} \left\{ -12c_1 m_n^2 [2\Gamma_0 - (2m_n^2 + q^2)G_0] - c_3[8k^3 - 12(2m_n^2 + q^2)\Gamma_0 - 6q^2 \Gamma_1 \right. \\
\left. + 3(2m_n^2 + q^2)^2 G_0] + 4c_4 \tilde{r}_1 \cdot \tilde{r}_2 (\bar{r}_1 \cdot \bar{r}_2 q^2 - \bar{r}_1 \cdot \bar{q} \bar{r}_2 \cdot \bar{q} G_2 - (3c_3 + c_4 \tilde{r}_1 \cdot \tilde{r}_2) i(\hat{r}_1 + \hat{r}_2) \cdot (\hat{q} \times \hat{p}) + [2\Gamma_0 + 2\Gamma_1 - (2m_n^2 + q^2)(G_0 + 2G_1)] - 12c_1 m_n^2 i(\bar{r}_1 + \bar{r}_2) \cdot (\bar{q} \times \bar{p})] G_0 + 2G_1 \right. \\
\left. + 4c_4 \tilde{r}_1 \cdot \tilde{r}_2 \bar{r}_1 \cdot (\bar{q} \times \bar{p}) \bar{r}_2 \cdot (\bar{q} \times \bar{p})] [G_0 + 4G_1 + 4G_3] \right\}. \] (31)

When substituting in the local regulator functions we obtain
\[ V_{NN}^{med,3} = \frac{g_A^2}{16\pi^2 f_F^2} \left\{ -12c_1 m_n^2 [2\Gamma_0' - (2m_n^2 + q^2)G_0'] - c_3[12 \Gamma_0' - 12(2m_n^2 + q^2)\Gamma_0' - 6q^2 \Gamma_1' \\
+ 3(2m_n^2 + q^2)^2 G_0'] + 4c_4 \tilde{r}_1 \cdot \tilde{r}_2 (\bar{r}_1 \cdot \bar{r}_2 q^2 - \bar{r}_1 \cdot \bar{q} \bar{r}_2 \cdot \bar{q} G_2' - (3c_3 + c_4 \tilde{r}_1 \cdot \tilde{r}_2) i(\hat{r}_1 + \hat{r}_2) \cdot (\hat{q} \times \hat{p}) + [2\Gamma_0' + 2\Gamma_1' - (2m_n^2 + q^2)(G_0' + 2G_1')] - 12c_1 m_n^2 i(\bar{r}_1 + \bar{r}_2) \cdot (\bar{q} \times \bar{p})] G_0' + 2G_1' \\
+ 4c_4 \tilde{r}_1 \cdot \tilde{r}_2 \bar{r}_1 \cdot (\bar{q} \times \bar{p}) \bar{r}_2 \cdot (\bar{q} \times \bar{p})] [G_0' + 4G_1' + 4G_3'] \right\}. \] (32)

In the above expressions we encounter the \( p \)- and \( q \)-dependent functions
\[ G_{0,*,**}(p, q) = \int_{-1}^{1} dk \int_{0}^{2\pi} dx \int_{0}^{2\pi} d\phi \frac{\{k^2, k^4, k^6\}/(2\pi)}{A^2 - B^2 \cos^2 \phi} F\left(p^2 + k^2 + kx \sqrt{4p^2 - q^2}\right) + qk \sqrt{1 - x^2 \cos \phi, \Lambda}) F\left(p^2 + k^2 + kx \sqrt{4p^2 - q^2}\right) - qk \sqrt{1 - x^2 \cos \phi, \Lambda}), \] (33)

where \( A = m_n^2 + p^2 + k^2 + kx \sqrt{4p^2 - q^2} \) and \( B = qk \sqrt{1 - x^2} \). In Eq. (31), the functions \( G_{0,*,**}(p, q) \) are obtained from Eq. (33) by substituting \( \Lambda \to \infty \). In addition we encounter the following \( p \)- and \( q \)-dependent functions
\[ G_1'(p, q) = \frac{\Gamma_0' - (m_n^2 + p^2)G_0' - G_*'}{4p^2 - q^2}, \] (34)
\[ G_1'(p, q) = \frac{3\Gamma_2' + p^2 \Gamma_3' - (m_n^2 + p^2)G_*' - G_{**}'}{4p^2 - q^2}, \] (35)
\[ G_2(p, q) = (m_n^2 + p^2)G_1' + G_*' + G_{1*}', \] (36)
\[ G_3(p, q) = \frac{1}{2}\Gamma_1' - 2(m_n^2 + p^2)G_1' - 2G_{1*}' - G_*', \] (37)
where

\[
\Gamma_0'(p,q) = \int_0^{k_f} dk \int_{-1}^{1} dx \int_0^{2\pi} d\phi \frac{k^2/(2\pi)}{m_\pi^2 + p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos \phi} \times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos \phi, \Lambda) \times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} - qk\sqrt{1 - x^2}\cos \phi, \Lambda),
\]

\[
\Gamma_1'(p,q) = \int_0^{k_f} dk \int_{-1}^{1} dx \int_0^{2\pi} d\phi \frac{k^2|x\sqrt{4p^2 - q^2} + q\sqrt{1 - x^2}\cos \phi|/(4\pi p^2)}{m_\pi^2 + p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos \phi} \times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos \phi, \Lambda) \times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} - qk\sqrt{1 - x^2}\cos \phi, \Lambda),
\]

\[
\Gamma_2'(p,q) = \int_0^{k_f} dk \int_{-1}^{1} dx \int_0^{2\pi} d\phi \frac{k^4\left[4p^2 - \left(x\sqrt{4p^2 - q^2} + q\sqrt{1 - x^2}\cos \phi\right)^2\right]/(16\pi p^4)}{m_\pi^2 + p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos \phi} \times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos \phi, \Lambda) \times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} - qk\sqrt{1 - x^2}\cos \phi, \Lambda),
\]

\[
\Gamma_3'(p,q) = \int_0^{k_f} dk \int_{-1}^{1} dx \int_0^{2\pi} d\phi \frac{k^4\left[3\left(x\sqrt{4p^2 - q^2} + q\sqrt{1 - x^2}\cos \phi\right)^2 - 4p^2\right]/(16\pi p^4)}{m_\pi^2 + p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos \phi} \times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} + qk\sqrt{1 - x^2}\cos \phi, \Lambda) \times F(p^2 + k^2 + kx\sqrt{4p^2 - q^2} - qk\sqrt{1 - x^2}\cos \phi, \Lambda),
\]

Additionally, we have replaced the quantity $8k_f^3$ in Eq. (31) with $12\Gamma'_4$ defined in Eq. (21). The term $8k_f^3$ in Eq. (31) as well as all unprimed $\Gamma$ and $G$ functions can be obtained by setting $\Lambda \to \infty$. For the $c_D$ vertex correction to one-pion exchange, Fig. 2(d), we previously had

\[
V_{NN}^{\text{med.4}} = -\frac{g_{ACD}k_f^3}{12\pi^2 f_\pi^4 \Lambda_\chi} \frac{\bar{\sigma}_1 \cdot \vec{q} \bar{\sigma}_2 \cdot \vec{q}}{m_\pi^2 + q^2} \vec{r}_1 \cdot \vec{r}_2.
\]

Including the local regulators we find

\[
V_{NN}^{\text{med.4}} = -\frac{g_{ACD}}{8\pi^2 f_\pi^4 \Lambda_\chi} \frac{\bar{\sigma}_1 \cdot \vec{q} \bar{\sigma}_2 \cdot \vec{q}}{m_\pi^2 + q^2} \vec{r}_1 \cdot \vec{r}_2 \left(\frac{4}{3} k_f^3 \mathcal{F}(q^2, \Lambda) - \Gamma'_4\right).
\]
For the $c_D$ vertex correction to the $2N$ contact term, Fig. 2(e), we previously had

\[
V_{NN}^\text{med,5} = \frac{g A c D}{16 \pi^2 f_\pi^4 \Lambda_x} \left\{ \vec{r}_1 \cdot \vec{r}_2 \left[ 2 \vec{\sigma}_1 \cdot \vec{\sigma}_2 \Gamma_2 + \left( \vec{\sigma}_1 \cdot q \vec{\sigma}_2 \cdot \vec{q} \left( 1 - \frac{2 p^2}{q^2} \right) \right) \right. \\
- \left. \frac{2}{q^2} \vec{\sigma}_1 \cdot \left( \vec{q} \times \vec{p} \right) \vec{\sigma}_2 \cdot \left( \vec{q} \times \vec{p} \right) \right) \left( \Gamma_0 + 2 \Gamma_1 + \Gamma_3 \right) \right\}. \tag{44}
\]

Including the local regulators we obtain

\[
V_{NN}^\text{med,5} = \frac{g A c D}{16 \pi^2 f_\pi^4 \Lambda_x} \left\{ \vec{r}_1 \cdot \vec{r}_2 \left[ 2 \vec{\sigma}_1 \cdot \vec{\sigma}_2 \Gamma_2 + \left( \vec{\sigma}_1 \cdot q \vec{\sigma}_2 \cdot \vec{q} \left( 1 - \frac{2 p^2}{q^2} \right) \right) \right. \\
- \left. \frac{2}{q^2} \vec{\sigma}_1 \cdot \left( \vec{q} \times \vec{p} \right) \vec{\sigma}_2 \cdot \left( \vec{q} \times \vec{p} \right) \right) \left( \tilde{\Gamma}_0 + 2 \tilde{\Gamma}_1 + \tilde{\Gamma}_3 \right) \right\} F(q^2, \Lambda). \tag{45}
\]

We reiterate that the above expressions are obtained in the center-of-mass frame assuming on-shell scattering conditions. In all cases, the expressions for the in-medium 2N interaction above are well behaved (no poles) and involve only elementary integrations.

3 APPLICATIONS OF DENSITY-DEPENDENT 2N INTERACTIONS TO NUCLEAR MANY-BODY SYSTEMS

3.1 Equation of state of cold nuclear matter

The equation of state of nuclear matter gives important insights into many properties of finite nuclei, including the volume and symmetry energy contributions to the binding energy in the semi-empirical mass formula, the saturated central density of medium-mass and heavy nuclei, as well as nuclear collective excitation modes and giant resonances. The equation of state is also essential for modeling neutron stars \cite{51, 52, 53, 54, 55, 56, 57, 58, 59}, including their birth in core-collapse supernovae, their radii as a function of mass, their tidal deformabilities in the presence of compact binary companions, and their moments of inertia. For relatively soft equations of state, the central densities of typical neutron stars with mass $M \simeq 1.4 M_\odot$ reach $n \simeq 3 n_0$ \cite{60}, where $n_0 = 0.16$ fm$^{-3}$ is the nucleon number density in the saturated interior of heavy nuclei. At such densities, three-body forces give a large contribution to the pressure and are therefore critical for understanding neutron star structure.

The first-order perturbative contribution (Hartree-Fock approximation) to the ground state energy of isospin-symmetric nuclear matter is given by

\[
E_{2N}^{(1)} = \frac{1}{2} \sum_{12} \langle 12 | \tilde{V}_{2N} | 12 \rangle n_1 n_2, \tag{46}
\]

for the antisymmetrized two-body force $\tilde{V}_{2N}$ and

\[
E_{3N}^{(1)} = \frac{1}{6} \sum_{123} \langle 123 | \tilde{V}_{3N} | 123 \rangle n_1 n_2 n_3, \tag{47}
\]
for the antisymmetrized three-body force $\bar{V}_{3N}$. In the above equations, $n_i = \theta(k_f - |\vec{k}_i|)$ is the zero-temperature Fermi-Dirac distribution function with Fermi momentum $k_f$, and the sum is taken over the momentum, spin, and isospin of the occupied states in the Fermi sea.

In Fig. 3 we show the density-dependence of the Hartree-Fock contribution to the ground state energy of isospin-symmetric nuclear matter from the N2LO chiral three-nucleon force in different approximations. As a representative example, we consider the low-energy constants $c_1 = -0.81$ GeV$^{-1}$, $c_3 = -3.4$ GeV$^{-1}$, $c_4 = 3.4$ GeV$^{-1}$, $c_D = -0.24$, and $c_E = -0.106$ obtained in Ref. [61] and associated with the N3LO NN chiral interaction with cutoff scale $\Lambda = 450$ MeV. We see that in all cases the first-order perturbative contribution from three-body forces in isospin-symmetric matter is strongly repulsive. The exact treatment of the Hartree-Fock contribution to the ground state energy arising from the N2LO three-nucleon force is shown in Fig. 3 as the thick black line labeled “$V_{3N,\text{exact}}^{A\to\infty}$”. Employing instead the density-dependent NN interaction $V_{\text{med}}$ with $\Lambda \to \infty$ we obtain the contribution shown with the thin blue line and labeled “$V_{\text{med}}^{A\to\infty}$”. Note that in order to avoid triple-counting when the density-dependent NN interaction $V_{\text{med}}$ is used in Eq. (46), we must replace $V_{3N} \to \frac{1}{2}V_{\text{med}}$. From Fig. 3 we observe that at the Hartree-Fock level the density-dependent NN interaction accurately reflects the physics encoded in the full three-body force. This is not a trivial observation since several approximations were employed to derive the density-dependent NN interaction from $V_{3N}$. In Fig. 3 we see that the largest deviation in the two curves is only 1 MeV (or $\approx 3\%$) at $n = 0.32$ fm$^{-3}$.

Implying the nonlocal regulator in Eq. (15) leads to the red dot-dashed line labeled “$V_{\text{med, nonloc}}^{A\to\infty}$”. As expected, the presence of the momentum-space cutoff reduces the Hartree-Fock contribution to the ground-state energy, particularly at high densities. However, the cutoff artifacts introduced are rather small and amount to only 0.8 MeV (or $\approx 2\%$) relative to the result from $V_{\text{med}}^{A\to\infty}$ at $n = 0.32$ fm$^{-3}$. We note that since the Hartree-Fock contribution to the ground state energy $E/A$ is always finite and probes only the characteristic physical energy scale of the system, the differences between $V_{\text{med}}^{A\to\infty}$ and $V_{\text{med, nonloc}}^{A\to\infty}$ are true regulator artifacts. We next impose the local regulator in Eq. (17), which is shown as the dotted green line in Fig. 3 and labeled “$V_{\text{med, loc}}^{A\to\infty}$”. For this choice of regulator we find severe cutoff artifacts, even at low densities where one would expect the role of the regulating function to be minimal. For example, at $n = 0.10$ fm$^{-3}$, there is a 19% relative error between $V_{\text{med}}^{A\to\infty}$ and $V_{\text{med, loc}}^{A\to\infty}$. From Eq. (17) we expect the regulator to introduce corrections at order $(Q/\Lambda)^4 \sim (k_f/\Lambda)^4$. The Fermi momentum at this density is $k_f = 225$ MeV, which for the $\Lambda = 450$ MeV chiral potential implies an error of $(k_f/\Lambda)^4 \approx 6\%$. One key difference between the nonlocal and local regulators of Eqs. (15) and (17) is that the relative momentum ranges from $0 < k < k_f$ while the momentum transfer ranges from $0 < q < 2k_f$. Therefore, one naturally expects larger cutoff artifacts for the local regulating function in Eq. (17). Indeed, when the value of the momentum-space cutoff is increased to $2\Lambda$, as can be seen from the dashed green curve of Fig. 3, the results from employing the local regulator are now comparable to those using the nonlocal regulator.

In Fig. 4 we show the density-dependence of the Hartree-Fock contribution to the ground state energy of pure neutron matter from the N2LO chiral three-nucleon force in different approximations. Again we consider the low-energy constants $c_1 = -0.81$ GeV$^{-1}$, $c_3 = -3.4$ GeV$^{-1}$, $c_4 = 3.4$ GeV$^{-1}$, $c_D = -0.24$, and $c_E = -0.106$ associated with the N3LO NN chiral interaction with cutoff scale $\Lambda = 450$ MeV. However, in pure neutron matter the Hartree-Fock contribution from three-body forces is independent of $c_4$, $c_D$, and $c_E$. We show as the thick black line labeled “$V_{3N,\text{exact}}^{A\to\infty}$” in Fig. 4 the Hartree-Fock contribution to the ground-state energy of pure neutron matter. Employing the density-dependent NN interaction $V_{\text{med}}$ with $\Lambda \to \infty$ we obtain the contribution shown with the thin blue line labeled “$V_{\text{med}}^{A\to\infty}$”. Again, at the
Hartree-Fock level the density-dependent NN interaction very accurately reproduces the result from the full three-body force.

Inserting the nonlocal regulator in Eq. (15) we find the red dot-dashed line labeled “$V_{\text{med, nonloc}}^\Lambda$”. The nonlocal regulator preserves the property that none of the three-body force terms proportional to $c_4$, $c_D$, and $c_E$ contribute to the ground-state energy of pure neutron matter. We find that the momentum-space cutoff reduces the Hartree-Fock contribution to the ground-state energy even more than that in isospin-symmetric nuclear matter. This is due to the larger neutron Fermi momentum (compared to the nucleon Fermi momentum in isospin-symmetric nuclear matter at the same density). The cutoff artifacts introduced are nevertheless relatively small and amount to 2 MeV at $n = 0.32 \text{ fm}^{-3}$. Finally, we impose the local regulator in Eq. (17) to obtain the dotted green line labeled “$V_{\text{med, loc}}^\Lambda$” in Fig. 4. Again, the cutoff artifacts are very large. For example, at $n = 0.10 \text{ fm}^{-3}$, there is now a 34% relative error between $V_{\text{med, loc}}^\Lambda$ and $V_{\text{med}}$. At this density, the maximum momentum transfer is $q = 2k_f \approx 570 \text{ MeV}$, which is clearly problematic for the chosen cutoff $\Lambda = 450 \text{ MeV}$. In addition to larger artifacts, the local regulator also induces contributions to the density-dependent NN interaction in pure neutron matter that now depend on the low-energy constants $c_4$, $c_D$, and $c_E$. In the case of pure neutron matter, diagrams (d), (e), and (f) in Fig. 2 produce $V_{NN}^{\text{med, } 4} = V_{NN}^{\text{med, } 5} = V_{NN}^{\text{med, } 6} = 0$ with either the nonlocal regulator or no regulator at all. Instead, for the local regulator we find

$$V_{NN}^{\text{med, } 4} = -\frac{g_A c_D}{8\pi^2 f_\pi^4 \Lambda_X} \frac{\vec{\sigma}_1 \cdot \vec{q} \vec{\sigma}_2 \cdot \vec{q}}{m_N^2 + q^2} \left( \frac{2}{3} k_f^3 F(q^2, \Lambda) - \Gamma_4' \right),$$

(48)
Holt et al. Implementing chiral three-body forces

Figure 4. Hartree-Fock contribution to the ground-state energy of pure neutron matter as a function of density due to the N2LO chiral three-nucleon force with cutoff scale $\Lambda = 450$ MeV.

which indeed vanishes when the local regulators are replaced by 1. For the $c_D$ vertex correction to the $2N$ contact term with local regulators we obtain

$$V_{NN}^{\text{med},5} = \frac{g_{ACD}}{16\pi^2 f_\pi^2 \Lambda} \left\{ 2\vec{\sigma}_1 \cdot \vec{\sigma}_2 \tilde{\Gamma}_2 + \left( \vec{\sigma}_1 \cdot \vec{\sigma}_2 \left( 2p^2 - \frac{q^2}{2} \right) + \vec{\sigma}_1 \cdot q \vec{\sigma}_2 \cdot q \left( 1 - \frac{2p^2}{q^2} \right) \right) \tilde{\Gamma}_0 + 2\tilde{\Gamma}_1 + 3\tilde{\Gamma}_3 \right\} F(q^2, \Lambda),$$

(49)

where $\tilde{\Gamma}_4(p)$ is defined in Eq. (20). Finally, the three-body contact term with the local regulator leads to

$$V_{NN}^{\text{med},6} = \frac{c_E}{2\pi^2 f_\pi^2 \Lambda} \left[ \frac{2}{3} k^2 F^2(q^2, \Lambda) - 2F(q^2, \Lambda)\tilde{\Gamma}_4(p) - \Gamma'_4(p, q) + \frac{4}{3} k^2 F(q^2, \Lambda) \right].$$

(50)

Again, this term vanishes when the regulating functions are set to 1. These additional terms have been included in the present of calculation of the dotted green line in Fig. 4. Substituting $\Lambda \to 2\Lambda$ into the nonlocal regulator again reduces the cutoff artifacts, as seen in the dashed green curve of Fig. 4.

The inclusion of three-body forces in the nuclear equation of state beyond the Hartree-Fock approximation remains challenging. While several recent works [62, 33] have computed the exact second-order contribution to the equation of state from three-body forces, the use of derived density-dependent two-body interactions allows for an approximate treatment up to third order in perturbation theory [61, 63]:

$$E^{(2)} = -\frac{1}{4} \sum_{\text{1234}} \langle 12 | \tilde{V}_{\text{eff}} | 34 \rangle^2 \frac{n_1 n_2 \bar{n}_3 \bar{n}_4}{e_3 + e_4 - e_1 - e_2},$$

(51)

$$E^{(3)}_{pp} = \frac{1}{8} \sum_{\text{123456}} \langle 12 | \tilde{V}_{\text{eff}} | 34 \rangle \langle 34 | \tilde{V}_{\text{eff}} | 56 \rangle \langle 56 | \tilde{V}_{\text{eff}} | 12 \rangle \frac{n_1 n_2 \bar{n}_3 \bar{n}_4 \bar{n}_5 \bar{n}_6}{(e_3 + e_4 - e_1 - e_2)(e_5 + e_6 - e_1 - e_2)},$$

(52)
A figure showing the equation of state of isospin-symmetric nuclear matter from chiral two- and three-body forces with different choices of the momentum-space cutoff $\Lambda$ and at different orders in many-body perturbation theory. The label $E^{(i)}$ denotes the $i$-th order in perturbation theory, and $\Sigma^{(n)}$ denotes the $n$-th order treatment of the self-energy. The shaded region below $n = 0.08 \text{ fm}^{-3}$ represents the approximate location of the spinodal instability.

The intermediate-state single-particle energies $e_i$ in Eqs. (53)-(54) can be treated in several different approximations. In the simplest case, they are taken as the free-space energies: $e(k) = k^2/2M$. More generally, they can be dressed with interaction lines in which case $e(k) = k^2/2M + \text{Re} \Sigma(e(k), k)$, where $\Sigma(e(k), k)$ is the self-consistent energy- and momentum-dependent nucleon self energy.

Third-order diagrams and fourth-order diagrams are found to give rather small contributions ($\sim 2 \text{ MeV}$) to the equation of state up to $n = 1.5n_0$ for potentials with momentum-space cutoffs $\Lambda \simeq 400 - 500 \text{ MeV}$. However, the intermediate-state energies in Eqs. (53)-(54) should be treated at least to second order in a perturbative expansion of the self-energy. In Fig. we plot the equation of state of isospin-symmetric nuclear matter for several different choices of the cutoff scale $\Lambda = 414, 450, 500 \text{ MeV}$ (represented by red, blue, and green colors respectively) and orders in many-body perturbation theory (denoted by the symbol). In all cases we employ an N3LO chiral nucleon-nucleon interaction with only the N2LO chiral three-body force with low-energy constants fitted to the binding energies of $^3\text{H}$ and $^3\text{He}$ as well as the beta-decay lifetime of $^3\text{H}$. For the density-dependent three-body force we use the nonlocal regulator in Eq. (15). From Figs. 3 and 4 we see that the local regulator in Eq. (17) would be highly constraining and only allow for a meaningful calculation of the nuclear equation of state below saturation density. In Fig. 5 the dotted lines denote the inclusion of second-order ground-state energy diagrams...
(\(E^{(2)}\)) with first-order self energies (\(\Sigma^{(1)}\)) for the intermediate-state propagators. The dashed lines denote the inclusion of second-order ground-state energy diagrams (\(E^{(2)}\)) with second-order self energies (\(\Sigma^{(2)}\)) for the intermediate-state propagators. From Fig. 5 we see that the second-order self energy diagrams contribute \(2 - 3\) MeV to the ground state energy per particle for densities \(n \geq 0.16\) fm\(^{-3}\). Finally, the solid lines denote the inclusion of third-order ground-state energy diagrams (\(E^{(3)}\)) with second-order self energies (\(\Sigma^{(2)}\)) for the intermediate-state propagators. In general, the sum of all third-order diagrams gives a relatively small contribution to the equation of state around saturation density. However, below the critical density for the spinodal instability (\(n_c \approx 0.08\) fm\(^{-3}\)) [65], denoted by the blue shaded region in Fig. 5, the third-order diagrams give somewhat large effects due to the breakdown of perturbation theory. Nevertheless, the saturation of nuclear matter is robust and both the empirical saturation density and energy are within the uncertainties predicted from chiral nuclear forces. We note that the ground state energy from the N3LO-414 and N3LO-450 chiral potentials are very similar in all approximations. Both potentials are known to converge very rapidly in perturbation theory compared to the N3LO-500 potential [63], which may partly explain the similarity of their results.

### 3.2 Nucleon-nucleus optical potentials

The theoretical description of nucleon-nucleus scattering and reactions can be greatly simplified through the introduction of optical model potentials, which replace the complicated two- and many-body interactions between projectile and target with an average one-body potential. In many-body perturbation theory, the optical potential can be identified as the nucleon self-energy, which in general is complex, nonlocal, and energy dependent:

\[
V(\vec{r}, \vec{r}'; E) = U(\vec{r}, \vec{r}'; E) + iW(\vec{r}, \vec{r}'; E). \tag{55}
\]

While phenomenological optical potentials [66] are fitted to a great amount of differential elastic scattering, total cross section, and analyzing power data, microscopic optical potentials can be constructed from high-precision two-nucleon and three-nucleon forces [67, 68, 69, 70, 71]. In chiral effective field theory, three-nucleon forces in particular have been shown [64, 72] to give rise to an overall repulsive single-particle potential at all projectile energies that increases strongly with the density of the medium. Three-nucleon forces are therefore essential for an accurate description of nucleon-nucleus scattering at moderate energies where the projectile penetrates the target nucleus.

In the Hartree-Fock approximation, the contribution to the nonlocal (but energy-independent) nucleon self energy is given by

\[
\Sigma^{(1)}_{2N}(q) = \sum_{1}\langle \vec{q}\,\vec{h}_1ss_1tt_1|\bar{V}_{2N}|\vec{q}\,\vec{h}_1ss_1tt_1\rangle n_1, \tag{56}
\]

where \(\bar{V}_{2N}\) denotes the antisymmetrized NN potential, \(n_1 = \theta(k_f - |\vec{h}_1|)\) is the zero-temperature Fermi-Dirac distribution function, and the sum is taken over the momentum, spin, and isospin of the intermediate hole state \(|\vec{h}_1, s_1, t_1\rangle\). The Hartree-Fock contribution from three-body forces is given by

\[
\Sigma^{(1)}_{3N}(q) = \frac{1}{2}\sum_{12}\langle \vec{q}\,\vec{h}_1\vec{h}_2; ss_1s_2; tt_1t_2|\bar{V}_{3N}|\vec{q}\,\vec{h}_1\vec{h}_2; ss_1s_2; tt_1t_2\rangle n_1n_2, \tag{57}
\]

where \(\bar{V}_{3N}\) is the fully-antisymmetrized three-body interaction. We have computed the Hartree-Fock contribution to the single-particle energy exactly [64] from Eq. (57) as well as from Eq. (56) using the density-dependent NN interaction \(V_{\text{med}}\). Note that in order to avoid double-counting we must replace \(\bar{V}_{2N} \to \frac{1}{2}V_{\text{med}}\) in Eq. (56).
Figure 6. Hartree-Fock contribution to the nucleon self energy in symmetric nuclear matter at saturation density $n_0$ from the N2LO chiral three-nucleon force with cutoff scale $\Lambda = 450$ MeV. Results are shown for an exact treatment as well as from the density-dependent interaction $V_{\text{med}}$ with different choices of regulating function (see text).

In Fig. 6 we demonstrate the accuracy of using the density-dependent NN interaction in place of the full three-body force when computing the Hartree-Fock contribution to the nucleon self energy. Specifically, we plot the momentum-dependent nucleon self-energy (note that both the 2N and 3N Hartree-Fock contributions are real and energy independent) in isospin-symmetric nuclear matter at saturation density $n_0$. The thick black curve labeled “$V_{3N,\text{exact}}$” is the exact result without a high-momentum regulator. The thin blue curve labeled “$V_{\Lambda \to \infty \text{med}}$” is obtained from the density-dependent NN interaction without regulator. We see that there is a systematic difference of $1−2$ MeV (or about 5%) between the two results across all momenta. This difference represents the inherent error introduced through the approximations employed in constructing the density-dependent NN interaction. Except for this systematic reduction in the nucleon self energy, we see that overall $V_{\text{med}}$ faithfully reproduces the exact Hartree-Fock self-energy across all momenta.

Introducing the nonlocal regulator in Eq. (15) results in the red dash-dotted line of Fig. 6. The artifacts associated with the nonlocal regulator grow rapidly for momenta beyond $p \simeq 400$ MeV and by $p \simeq 600$ MeV the three-nucleon force contribution to the self energy is reduced by $\sim 25\%$. This corresponds to a lab energy of about $E_{\text{lab}} \simeq 175$ MeV [72] beyond which a description of nucleon-nucleus scattering in terms of chiral optical potentials becomes highly questionable. Introducing the local regulator in Eq. (17) leads to the dotted green curve in Fig. 6. We see that this regulator generates artifacts (of at least 15%) even for low-momentum particles in isospin-symmetric nuclear matter at saturation density. This is due to the already large nucleon Fermi momentum $(k_f \simeq 270$ MeV) in nuclear matter at this density. Finally, if we double the value of the momentum-space cutoff in the local regulating function, we find the results given by the dashed green curve in Fig. 6. Again, this choice of cutoff leads to artifacts that are on par with those from the nonlocal regulator but which are noticeably smaller at the largest momenta considered.

In Fig. 7 we plot the value of the Hartree-Fock single-particle potential at the Fermi momentum $(p = k_f)$ from chiral three-body forces for densities up to $n \simeq 2n_0$. This contribution to the single-particle
energy from the chiral 3NF grows approximately quadratically with the density. Again we find that the density-dependent NN interaction from the leading chiral three-nucleon force reproduces well the exact Hartree-Fock result. The artifacts introduced through the nonlocal regulator in Eq. (15), the local regulator in Eq. (17), and the local regulator with $\Lambda_{\text{loc}} = 2\Lambda_{\text{nonloc}}$ follow the same trends already observed in the Hartree-Fock contribution to the equation of state.

Recently, several works [64, 72] have included the second-order contributions to the nucleon self energy (both in isospin-symmetric and asymmetric nuclear matter):

$$\Sigma^{(2a)}_{2N}(q, \omega) = \frac{1}{2} \sum_{123} |\langle \vec{p}_1 \vec{p}_3 s_1 s_3 t_1 t_3 | \tilde{V}_{\text{eff}} | \vec{q} \vec{p}_2 s_2 t_2 \rangle|^2 \frac{\omega + e_2 - e_1 - e_3 + i\eta}{\bar{n}_1 n_2 \bar{n}_3}$$

and

$$\Sigma^{(2b)}_{2N}(q, \omega) = \frac{1}{2} \sum_{123} |\langle \vec{h}_1 \vec{h}_3 s_1 s_3 t_1 t_3 | \tilde{V}_{\text{eff}} | \vec{q} \vec{p}_2 s_2 t_2 \rangle|^2 \frac{\omega + e_2 - e_1 - e_3 - i\eta}{n_1 \bar{n}_2 n_3},$$

with the antisymmetrized potential $\tilde{V}_{\text{eff}} = \tilde{V}_{2N} + \tilde{V}_{\text{med}}$ that includes the density-dependent interaction from the N2LO chiral three-body force. The single-particle energies in Eqs. (58) and (59) are computed self-consistently according to

$$e(q) = \frac{q^2}{2M} + \text{Re} \Sigma(e(q), q).$$

Generically, Eqs. (58) and (59) give rise to complex and energy-dependent single-particle potentials. This allows for the construction of nucleon-nucleus optical potentials that have been shown [73] to reproduce well differential elastic scattering cross sections for proton projectiles on a range of calcium targets up to about $E = 150$ MeV.

---

**Figure 7.** Hartree-Fock contribution to the nucleon self energy at the Fermi momentum ($p = k_f$) in symmetric nuclear matter as a function of density from the N2LO chiral three-nucleon force with cutoff scale $\Lambda = 450$ MeV. Results are shown for an exact treatment as well as from the density-dependent interaction $V_{\text{med}}$ with different choices of regulating function (see text).
The general form of phenomenological optical potentials for nucleon-nucleus scattering is given by

\[
U(r, E) = V_V(r, E) + iW_V(r, E) + iW_D(r, E) + V_{SO}(r, E) \vec{\ell} \cdot \vec{s} + iW_{SO}(r, E) \vec{\ell} \cdot \vec{s} + V_C(r),
\]

consisting of a real volume term, an imaginary volume term, an imaginary surface term, a real spin-orbit term, an imaginary spin-orbit term, and finally a central Coulomb interaction. In Eq. (61), \( \vec{\ell} \) and \( \vec{s} \) are the single-particle orbital angular momentum and spin angular momentum, respectively. To construct a microscopic nucleon-nucleus optical potential from the nuclear matter approach, one can employ the local density approximation (LDA):

\[
V(E; r) + iW(E; r) = V(E; \kappa^p(r), \kappa^n(r)) + iW(E; \kappa^p(r), \kappa^n(r)),
\]

where \( \kappa^p(r) \) and \( \kappa^n(r) \) are the local proton and neutron Fermi momenta. This approach can be improved by taking account of the finite range of the nuclear force through the improved local density approximation (ILDA):

\[
V(E; r)_{ILDA} = \frac{1}{(t\sqrt{\pi})^3} \int V(E; r') e^{-\frac{|r-r'|^2}{t^2}} d^3r',
\]

which introduces an adjustable length scale \( t \) taken to be the typical range of the nuclear force. In previous works [74,73] this Gaussian smearing factor was chosen to be \( t \approx 1.2 \) fm and varied in order to estimate the introduced theoretical uncertainties.

The ILDA approach starts by defining the isoscalar and isovector density distributions for a given target nucleus. In our previous works [73,75], we have employed for this purpose Skyrme energy density functionals fitted to the equation of state of isospin-asymmetric nuclear matter [76] calculated from the same chiral two- and three-body forces used to compute the nucleon self energy in Eqs. (56)–(59). The Gaussian smearing factor \( t \) in the ILDA was chosen in the range \( 1.15 \) fm \( \leq t \leq 1.25 \) fm. The real part of the optical potential is found [73] to be in excellent agreement with that from phenomenological optical potentials [66], however, the microscopic imaginary part exhibits a surface peak that is too small and a volume contribution that grows too strongly with energy. This leads to larger total reaction cross sections [73] compared to phenomenology and experiment. This is in fact a general feature of the microscopic nuclear matter approach [77,78] independent of the choice of nuclear potential, and previous works [74,79] have attempted to mitigate this deficiency by introducing scaling factors for the imaginary part.

In Fig. 8, we plot the differential elastic scattering cross sections for proton projectiles on \(^{40}\)Ca and \(^{48}\)Ca isotopes from microscopic optical potentials derived in chiral effective field theory. In this study we employ the N3LO nucleon-nucleon potential with momentum-space cutoff \( \Lambda = 450 \) MeV together with the density-dependent NN interaction using the nonlocal regulator in Eq. (15). From Fig. 8 we see that the predictions from chiral effective field theory (shown in blue) reproduce well the elastic scattering cross section data (red dots) from \( E = 25 - 45 \) MeV. The small uncertainty band associated with the blue curve is due entirely to variations in the ILDA Gaussian smearing factor. In some cases, the results from chiral nuclear optical potentials give better agreement with experiment than the Koning-Delaroche phenomenological optical potential (shown as the green dashed line in Fig. 8). In contrast to semi-microscopic approaches [74,79] that introduce energy-dependent scaling factors for the real and imaginary parts of the optical potential, our calculations are not fitted in any way to scattering data. Qualitatively similar results have been found [73] for proton energies as low as \( E \approx 2 \) MeV and as high as \( E \approx 160 \) MeV. Moreover, the construction of neutron-nucleus optical potentials is in progress [75] and preliminary results for differential elastic scattering cross sections are found to be of similar quality to the case of proton-nucleus scattering.
3.3 Quasiparticle interaction in nuclear matter

Landau’s theory of normal Fermi liquids [80, 81, 82] remains a valuable theoretical framework for understanding the excitations, response, and transport coefficients of nuclear many-body systems [83, 84]. Fermi liquid theory is based on the concept of quasiparticles, i.e., dressed single-particle excitations of a (potentially) strongly-interacting many-body system that retain key properties of the bare particles in the analogous non-interacting system. In this way, Fermi liquid theory allows for a convenient description of the low-energy excitations of the interacting system and in the context of the nuclear many-body problem helps justify the nuclear shell model and the independent-particle description of nuclei and nuclear matter. The theory is made quantitative through the introduction of the quasiparticle interaction $F$, defined as the second functional derivative of the energy with respect to the quasiparticle distribution function $n(\vec{p})$:

$$E = E_0 + \sum_i e_{\vec{p}_i} \delta n_{\vec{p}_is_1t_1} + \frac{1}{2\Omega} \sum_{12} F(\vec{p}_1s_1t_1; \vec{p}_2s_2t_2) \delta n_{\vec{p}_is_1t_1} \delta n_{\vec{p}_2s_2t_2} ,$$  \hspace{1cm} (64)

where $E_0$ is the ground state energy, $\Omega$ is a normalization volume, and $\delta n_{\vec{p}_is_1t_1}$ is the change in occupation number of state $i$. In Eq. (64) the quasiparticle interaction $F$ in momentum space has units $\text{fm}^2$, $s_i$ labels
Implementing chiral three-body forces

Figure 9. Diagrammatic contributions to the quasiparticle interaction up to second order in perturbation theory. Wavy lines denote the antisymmetrized nuclear interaction.

the spin quantum number of quasiparticle $i$, and $t_i$ labels the isospin quantum number. Enforcing the symmetries of the strong interaction and assuming that the quasiparticles lie exactly on the Fermi surface leads to the general form of the quasiparticle interaction:

$$\mathcal{F}(\vec{p}_1, \vec{p}_2) = \mathcal{A}(\vec{p}_1, \vec{p}_2) + \mathcal{A}'(\vec{p}_1, \vec{p}_2) \vec{\tau}_1 \cdot \vec{\tau}_2,$$

where $\mathcal{A}(\vec{p}_1, \vec{p}_2) = f(\vec{p}_1, \vec{p}_2) + g(\vec{p}_1, \vec{p}_2) \vec{\sigma}_1 \cdot \vec{\sigma}_2 + h(\vec{p}_1, \vec{p}_2) S_{12}(\hat{\vec{p}}) + k(\vec{p}_1, \vec{p}_2) S_{12}(\hat{\vec{p}})$

$$+ \ell(\vec{p}_1, \vec{p}_2) (\vec{\sigma}_1 \times \vec{\sigma}_2) \cdot (\hat{\vec{p}} \times \hat{\vec{P}}),$$

and likewise for $\mathcal{A}'$ except with the replacement $\{f, g, h, k, \ell\} \rightarrow \{f', g', h', k', \ell'\}$. The relative momentum is given by $\vec{p} = \vec{p}_1 - \vec{p}_2$, the center-of-mass momentum is defined by $\vec{P} = \vec{p}_1 + \vec{p}_2$, and the tensor operator has the form $S_{12}(\hat{\vec{v}}) = 3\vec{\sigma}_1 \cdot \hat{\vec{v}} \vec{\sigma}_2 \cdot \hat{\vec{v}} - \vec{\sigma}_1 \cdot \vec{\sigma}_2$.

For two quasiparticle momenta on the Fermi surface ($|\vec{p}_1| = |\vec{p}_2| = k_f$), the scalar functions $\{f, g, h, k, \ell, f', g', h', k', \ell'\}$ depend only the angle $\theta$ between and $\vec{p}_1$ and $\vec{p}_2$. The quasiparticle interaction can therefore be written in terms of Legendre polynomials:

$$f(\vec{p}_1, \vec{p}_2) = \sum_{L=0}^{\infty} f_L(k_f) P_L(\cos \theta), \quad f'(\vec{p}_1, \vec{p}_2) = \sum_{L=0}^{\infty} f'_L(k_f) P_L(\cos \theta), \ldots$$

where $\cos \theta = \hat{\vec{p}}_1 \cdot \hat{\vec{p}}_2$, $q = 2k_f \sin(\theta/2)$, and $P = 2k_f \cos(\theta/2)$. The coefficients $f_L, f'_L, \ldots$ are referred to as the Fermi liquid parameters. Dimensionless Fermi liquid parameters $F_L, F'_L, \ldots$ can be defined by multiplying $f_L, f'_L, \ldots$ by the density of states, e.g., for symmetric nuclear matter:

$$N_0 = 2M^* k_f / \pi^2,$$

where $M^*$ the effective nucleon mass.

Originally, Fermi liquid theory was treated as a phenomenological model [83] in which the lowest-order Fermi liquid parameters would be constrained by select experimental data. From the Brueckner-Goldstone linked diagram expansion for the ground-state energy, see e.g., Eqs. (46)–(54), a diagrammatic expansion for the quasiparticle interaction in terms of the nuclear potential can be obtained [86] by performing functional derivatives with respect to the occupation probabilities. Up to second order in perturbation
theory one obtains for a general two-body interaction $V_{2N}$:

$$\mathcal{F}_{2N}^{(1)}(\vec{p}_1 s_1 t_1; \vec{p}_2 s_2 t_2) = \langle 12 | \tilde{V}_{2N} | 12 \rangle$$ (69)

$$\mathcal{F}_{2N}^{(2pp)}(\vec{p}_1 s_1 t_1; \vec{p}_2 s_2 t_2) = \frac{1}{2} \sum_{mn} \frac{|\langle 12 | \tilde{V}_{2N} | mn \rangle|^2 n_m \bar{n}_n}{e_1 + e_2 - e_m - e_n}$$ (70)

$$\mathcal{F}_{2N}^{(2hh)}(\vec{p}_1 s_1 t_1; \vec{p}_2 s_2 t_2) = \frac{1}{2} \sum_{ij} \frac{|\langle ij | \tilde{V}_{2N} | 12 \rangle|^2 n_i n_j}{e_i + e_j - e_1 - e_2}$$ (71)

$$\mathcal{F}_{2N}^{(2ph)}(\vec{p}_1 s_1 t_1; \vec{p}_2 s_2 t_2) = -2 \sum_{jn} \frac{|\langle 1j | \tilde{V}_{2N} | 2n \rangle|^2 n_j \bar{n}_n}{e_1 + e_j - e_2 - e_n},$$ (72)

which correspond respectively to diagrams (a), (b), (c), and (d) in Fig. 9. The first-order contribution in Eq. (69) is just the antisymmetrized two-body potential for two nucleons restricted to the Fermi surface. It contains only the four central terms $f, f', g, g'$ as well as the two relative momentum tensor interactions $h, h'$. The second-order contributions in Eqs. (70)–(72) give rise generically to the center-of-mass tensor interactions $k, k'$, but only the particle-hole term Eq. (72) can generate the cross-vector interactions $l, l'$ through the interference of a spin-orbit interaction with any other non-spin-orbit component in the bare nucleon-nucleon potential [87].

The expressions in Eqs. (69)–(72) can be decomposed into partial wave matrix elements of the bare nucleon-nucleon potential or the derived medium-dependent 2N interaction. In Section 4.1 below, we give explicit expressions for the partial-wave matrix elements of the density-dependent 2N interaction derived from the N2LO [47] and N3LO [88, 89] chiral three-body force. To date, the contributions from the N2LO chiral three-body force have been included [87, 90, 91] exactly in the calculation of the quasiparticle interaction in isospin-symmetric nuclear matter and pure neutron matter. At first order in perturbation theory, the second functional derivative of Eq. (47) leads to

$$\mathcal{F}_{3N}^{(1)}(\vec{p}_1 s_1 t_1, \vec{p}_2 s_2 t_2) = \sum_i n_i \langle i | \tilde{V}_{3N} | i 12 \rangle,$$ (73)

where $\tilde{V}_{3N}$ is the fully antisymmetrized three-body force. This is equivalent to the definition of the density-dependent NN interaction in Eq. (11) but restricted by the kinematics of quasiparticles lying on the Fermi surface. Moreover, the use of the in-medium 2N interaction constructed assuming on-shell scattering in the center-of-mass frame is not appropriate (in particular, it would give no center-of-mass dependence at leading order in Eq. (73)). Explicit and exact expressions (in the absence of a momentum-space cutoff) for the Landau Fermi liquid parameters in Egs. (65)–(67) from the N2LO chiral three-nucleon force have therefore been derived in Ref. [91]. Only the higher-order perturbative contributions to the quasiparticle interaction (where medium effects are included through normal Pauli blocking of intermediate states) utilize the in-medium 2N interaction derived in the center-of-mass frame. In the following we highlight their qualitative significance on the different terms of the quasiparticle interaction.

In Fig. 10 we plot the dimensionless Fermi liquid parameters associated with the $L = 0, 1$ Legendre polynomials (black and red dotted lines respectively) in isospin-symmetric nuclear matter from the N2LO chiral three-body force as a function of the nucleon density (up to $n = 0.4 \text{fm}^{-3}$). Although one may be skeptical of results from chiral effective field theory beyond $n \approx 2n_0$, the Landau parameters must obey
Figure 10. Density-dependent dimensionless Fermi liquid parameters in isospin-symmetric nuclear matter. Dotted lines symbolize the first-order perturbative contribution from three-body forces, while solid lines represent the sum of all second-order contributions including two- and three-body forces.

stability inequalities, e.g.,

\[ Q_L > -(2L + 1), \]  

(74)
where $Q \in \{F, F', G, G'\}$, for the central components of the quasiparticle interaction. Therefore we find it informative to speculate on the high-density behavior of the Landau parameters, since they might give hints toward possible instability mechanisms in dense matter. We note that complete stability conditions involving all spin-dependent interactions $H, K, L$ (and $H', K', L'$) that couple to $G$ (and $G'$) have not yet been worked out. To date only the effect of the relative tensor quasiparticle interaction has been considered \[92\]. We have found that in the presence of such Pomeranchuk instabilities, perturbation theory itself can be poorly behaved. For instance, in symmetric nuclear matter with density $n \lesssim n_0/2$ (where $F_0 < -1$ and nuclear matter is unstable to density fluctuations), we have computed also the third-order particle-particle contributions to the Fermi liquid parameters and found that $F_0$ is of comparable size to the second-order particle-particle diagrams. For other Fermi liquid parameters, however, the third-order particle-particle contributions are generally small at low densities.

The dotted lines in Fig. [10] are obtained from only the leading contribution due to three-body forces in Eq. (73). The solid lines represent the Fermi liquid parameters obtained from the sum of two- and three-body forces up to second order in perturbation theory. For the second-order contributions in Eqs. (70)−(72) we have replaced the two-body interaction $V_{2N}$ with $V_{2N} + V_{\text{med}}$, where $V_{2N}$ is the N3LO-450 potential and $V_{\text{med}}$ is the consistent density-dependent interaction constructed from the N2LO three-body force with nonlocal regulator. For several Fermi liquid parameters, we see that three-body forces provide the dominant contribution at high density. For instance, the strong increase in the $F_0$ Landau parameter (top left panel of Fig. 10) as a function of density is a direct result of the first-order contribution from three-body forces. The nuclear matter incompressibility $K = \frac{9\partial P}{\partial \rho}$, where $P = \rho^2 \frac{\partial (E/A)}{\partial \rho}$, is related to the $F_0$ Landau parameter through

$$K = \frac{3k_f^2}{M^*} (1 + F_0),$$  \quad (75)

where $M^*$ is the nucleon effective mass, and therefore three-body forces play a central role in the saturation mechanism \[7\] of nuclear matter with chiral nuclear forces. On the other hand, in some cases three-body forces play only a minor role, such as for the Landau parameters $F_1$ and $F'_0$. The former is related to the nucleon effective mass through

$$\frac{M^*}{M} = 1 + \frac{F_1}{3},$$ \quad (76)

and the latter is related to the nuclear isospin-asymmetry energy through

$$S_2 = \frac{k_f^2}{6M^*} (1 + F'_0),$$ \quad (77)

where $S_2$ is defined as the first term in a power series expansion of the nuclear equation of state about the isospin-symmetric configuration:

$$E \frac{A}{A}(n, \delta_{np}) = E \frac{A}{A}(n, 0) + S_2(n)\delta_{np}^2 + \cdots$$ \quad (78)

with $\delta_{np} = \frac{n_n - n_p}{n_n + n_p}$.

In general, we see from Fig. [10] that the noncentral components $K$ and $L$ of the quasiparticle interaction that depend explicitly on the center-of-mass momentum $\vec{P}$ are small at nuclear saturation density. However, several of the associated Fermi liquid parameters, such as $K'_0$, $L_0$, and $L'_1$ begin to grow rapidly for higher densities. Therefore, even though there has been little motivation to include such terms in modern energy
density functionals fitted to the properties of finite nuclei, such novel interactions may become more relevant in applications related to neutron star physics. The full quasiparticle interaction in pure neutron matter has already been computed [87] with modern chiral two- and three-nucleon forces. One finds again an enhanced role of three-body forces on the incompressibility of pure neutron matter and therefore the stability of neutron stars against gravitational collapse. The more general case of the quasiparticle interaction in nuclear matter at arbitrary isospin-asymmetry is in progress.

4 CHIRAL THREE-NUCLEON FORCE AT NEXT-TO-NEXT-TO-NEXT-TO-LEADING ORDER

Up to now we have considered only the chiral three-body force at N2LO. At order N3LO in the chiral power counting, additional three- and four-nucleon forces arise without any additional undetermined low-energy constants. However, except in the case of pure neutron matter, the inclusion of the N3LO three-body contributions requires a refitting of the three-body low-energy constants \( c_D \) and \( c_E \). The N3LO three-body force is written schematically as

\[
V^{(4)}_{3N} = V^{(4)}_{1\pi - \text{cont.}} + V^{(4)}_{2\pi - \text{cont.}} + V^{(4)}_{1/M} + V^{(4)}_{2\pi} + V^{(4)}_{2\pi - 1\pi} + V^{(4)}_{\text{ring}},
\]

(79)
corresponding to the \( 1\pi - \text{contact} \), \( 2\pi - \text{contact} \), relativistic \( 1/M \), \( 2\pi \), \( 2\pi - 1\pi \), and ring topologies, respectively. All contributions have been worked out and presented in Refs. [28, 29, 30]. Although we will not consider their specific effects in the present work, we note that the leading four-nucleon forces have been calculated in Ref. [31]. In deriving the density-dependent 2N interaction at N3LO, we take the expressions from Refs. [29, 30] based on the method of unitary transformations.

The density-dependent 2N interaction from the short-range terms and relativistic corrections, shown diagrammatically in Fig. 11(a) and (b), was computed first in Ref. [88]. Results were derived in the absence of a regulating function depending explicitly on the value of the intermediate-state momentum \( k_\| \) in Eq. (11). The resulting expressions for \( V_{\text{med}} \) obtained from the N3LO 3N force could therefore be simplified to analytical expressions involving at most a one-dimensional integration. In Ref. [88] it was found that the \( 1\pi - \text{exchange contact topology proportional to the 2N low-energy constant} \ C_T \) gives rise to a vanishing contribution to \( V_{\text{med}} \) in isospin-symmetric nuclear matter. The density-dependent 2N interaction derived from the long-range contributions to the N3LO three-body force, shown diagrammatically in Fig. 11(c), (d), and (e), was calculated in Ref. [89]. Again, the integration over the three-dimensional filled Fermi sphere could be performed up to at most one remaining integration. The formulas for the density-dependent
NN interaction from the N3LO three-body force are quite lengthy, and we refer the reader to Refs. [88, 89] for additional details.

4.1 Partial-wave decomposition

The analytical expressions for the medium-dependent 2N potential \( V_{\text{med}} \) obtained from the N3LO chiral three-body force [88, 89] can be conveniently understood by examining their attractive or repulsive effects in various partial waves. For comparison we will show also the lowest-order partial-wave contributions from the N2LO chiral three-body force, however, we note that the values of the three-body contact terms will need to be refitted in order to make a consistent comparison. In all cases, we choose the values \( c_D = 1.00 \) and \( c_E = -0.106 \), which have been used in other calculations presented in this work. We recall that the low-energy constants \( c_D \) and \( c_E \) of the N2LO chiral 3N force are fitted (including the N3LO chiral 2N interaction with cutoff scale \( \Lambda = 450 \text{ MeV} \)) to the binding energies of \( ^2\text{H} \) and \( ^3\text{He} \) as well as the beta-decay lifetime of \( ^3\text{H} \). Comparing to the values of \( c_D \) and \( c_E \) fitted in combination with the N2LO two-body force (see Table II of Ref. [12]), we do not expect qualitative differences in the results below coming from these two different choices in the chiral order. For the leading-order (LO) contact term \( C_T \) that appears in the \( 1\pi \) and \( 2\pi \)-contact topologies, we use the value \( C_T = -2.46491 \text{ GeV}^{-2} \) from the N3LO-450 2N potential.

We follow the description in Ref. [93] to obtain the diagonal momentum-space partial-wave matrix elements of the density-dependent NN interaction. With start with the form of a general nucleon-nucleon potential:

\[
V(\vec{p}, \vec{q}) = V_C + i \cdot \vec{r}_2 W_C + [V_S + \vec{r}_1 \cdot \vec{r}_2 W_S] \vec{\sigma}_1 \cdot \vec{\sigma}_2 + [V_T + \vec{r}_1 \cdot \vec{r}_2 W_T] \vec{\sigma}_1 \cdot (\vec{q} \times \vec{p}) + \left[ V_{SO} + \vec{r}_1 \cdot \vec{r}_2 W_{SO} \right] i(\vec{\sigma}_1 \cdot \vec{\sigma}_2) \cdot (\vec{q} \times \vec{p}) + \left[ V_Q + \vec{r}_1 \cdot \vec{r}_2 W_Q \right] \vec{\sigma}_1 \cdot \vec{q} \vec{\sigma}_2 \cdot (\vec{q} \times \vec{p}),
\]

where the subscripts refer to the central (C), spin-spin (S), tensor (T), spin-orbit (SO), and quadratic spin orbit (Q) components, each with an isoscalar (V) and isovector (W) version. The diagonal (in momentum space) partial-wave matrix elements for different spin and orbital angular momentum channels are then given in terms of the functions \( U_K = V_K + (4I - 3)W_K \), where \( K \in \{C, S, T, SO, Q\} \) and the total isospin quantum number takes the values \( I = 0, 1 \). Explicit expressions can be found in Ref. [47].

In Fig. [12] we show the \( ^1S_0, ^3S_1, ^3D_1, ^3S_1 - ^3D_1 \) diagonal momentum-space matrix elements of \( V_{\text{med}} \) from the N2LO (blue circles) and N3LO (red diamonds) chiral three-nucleon force in isospin-symmetric nuclear matter at the density \( n = n_0 \). Note that we have multiplied the matrix elements by the nucleon mass \( M \) to obtain dimensions of [fm]. Interestingly, we observe that the total N3LO three-body force in these partial-wave channels is roughly equal in magnitude but opposite in sign compared to the N2LO three-body force. Whereas the N2LO three-body force is largely repulsive in symmetric nuclear matter at saturation density, the N3LO three-body force is strongly attractive, except in the case of the coupled \( ^3S_1 - ^3D_1 \) tensor channel. One should keep in mind, however, that the low-energy constants \( c_D \) and \( c_E \) must be refitted after the introduction of the N3LO three-body force. One might expect from the above observations that the N2LO three-body force would be enhanced in order to offset the opposite behavior introduced from the N3LO three-body force in the lowest partial-wave channels.

In Fig. [13] we show the \( ^1P_1, ^3P_0, ^3P_1, \) and \( ^3P_2 \) diagonal momentum-space matrix elements of \( V_{\text{med}} \) from the N2LO (blue circles) and N3LO (red diamonds) chiral three-nucleon force in isospin-symmetric nuclear matter at the density \( n = n_0 \). In both the \( ^1P_1 \) and \( ^3P_0 \) channels, the N2LO and N3LO contributions are approximately equal in magnitude but opposite in sign. In the \( ^3P_1 \) channel, which is repulsive in the bare
Figure 12. Diagonal momentum-space matrix elements of $V_{\text{med}}$ associated with the total N2LO and N3LO three-body force in the $1S_0$ and $3S_1 - 3D_1$ partial-wave channels at $n = n_0$ in isospin-symmetric nuclear matter.

The long-range parts of the N3LO chiral three-body force are expected [97] to give larger contributions to the equation of state than the relativistic $1/M$ corrections and the $2\pi - 1\pi$ -contact topologies. Due to the large number of contributions to $V_{\text{med}}$ at N3LO, we only show selected results for individual topologies. In Fig. 14, we plot several of the dominant pion-ring contributions to the $1S_0$ partial-wave matrix elements for the density-dependent NN interaction derived from the N3LO chiral three-body force. We see that individual long-range contributions are large, but sizable cancellations lead to an overall reduced attractive $1S_0$ partial-wave channel at low momenta. In Fig. 15, we plot several of the important $2\pi$, $2\pi - 1\pi$, and ring topology contributions to the $3P_0$ partial-wave matrix elements of the density-dependent NN interaction derived from the N3LO chiral three-body force. We again find large cancellations among individual terms, but the sum produces significant attraction in this partial-wave channel.
Figure 13. Diagonal momentum-space matrix elements of $V_{\text{med}}$ associated with the total N2LO and N3LO three-body force in the $^1P_1$, $^3P_0$, $^3P_1$, and $^3P_2$ partial-wave channels at $n = n_0$ in isospin-symmetric nuclear matter.

5 SUMMARY AND CONCLUSIONS

We have reviewed the construction and implementation of density-dependent two-body interactions from three-body forces at N2LO and N3LO in the chiral expansion. We showed that at leading order in many-body perturbation theory, the in-medium 2N interaction reproduces very well the exact contributions to
the nuclear equation of state and nucleon self energy from the complete three-body force. The standard nonlocal high-momentum regulator used in our previous works leads to simpler analytical expressions for the density-dependent 2N interaction, consistency with the bare 2N potential, and relatively small artifacts in both the equation of state up to twice saturation density and the single-particle potential up to $p \simeq 400 - 500$ MeV at nuclear matter saturation density. Local 3N regulators with the same value of the cutoff, $\Lambda_{\text{loc}} = \Lambda_{\text{nonloc}}$, have been commonly used in previous studies of nuclear few-body systems, but these are shown to produce very large artifacts, even in the nuclear equation of state at saturation density. This could be remedied by choosing a local regulating function with $\Lambda_{\text{loc}} = 2\Lambda_{\text{nonloc}}$, which is well motivated since the momentum transfer $q$ can reach values twice as large as the relative momentum for two particles on the Fermi surface.

The use of medium-dependent two-body interactions has been shown to facilitate the implementation of three-body forces in higher-order perturbative calculations of the nuclear equation of state, single-particle potential, and quasiparticle interaction. In particular, nuclear matter was shown to saturate at the correct binding energy and density within theoretical uncertainties when computed up to third-order in perturbation theory. Moreover, microscopic nucleon-nucleus optical potentials derived from chiral two- and three-body forces have been shown to accurately predict proton elastic scattering cross sections on calcium isotopes up to projectile energies of $E \simeq 150$ MeV. The use of medium-dependent NN potentials derived from the N3LO chiral three-body force for calculations of the nuclear equation of state, single-particle potential, and quasiparticle interaction remain a topic of future research. As a first step, we have performed a partial-wave decomposition of $V_{\text{inel}}$ at N3LO in the chiral expansion and shown that the effective interaction is expected to be attractive in symmetric nuclear matter around saturation density.

**CONFLICT OF INTEREST STATEMENT**

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.
FUNDING

Work of J. W. H. is supported by the National Science Foundation under Grant No. PHY1652199 and by the U.S. Department of Energy National Nuclear Security Administration under Grant No. DE-NA0003841. The work of M. K. was supported in part by JSPS Grant-in-Aid for JSPS Research Fellow No. 18J15329. The work of N. K. has been supported in part by DFG and NSFC (CRC110).

ACKNOWLEDGMENTS

Portions of this research were conducted with the advanced computing resources provided by Texas A&M High Performance Research Computing. This manuscript has been released as a Pre-Print at [98].
