An Improved Convergence Analysis of Cyclic Block Coordinate Descent-type Methods for Strongly Convex Minimization

Tuo Zhao, Xingguo Li, Raman Arora, Han Liu and Mingyi Hong

Abstract

The cyclic block coordinate descent-type (CBCD-type) methods have shown remarkable computational performance for solving strongly convex minimization problems. Typical applications include many popular statistical machine learning methods such as elastic-net regression, ridge penalized logistic regression, and sparse additive regression. Existing optimization literature has shown that the CBCD-type methods attain iteration complexity of $O(p \cdot \log(1/\epsilon))$, where $\epsilon$ is a pre-specified accuracy of the objective value, and $p$ is the number of blocks. However, such iteration complexity explicitly depends on $p$, and therefore is at least $p$ times worse than those of gradient descent methods. To bridge this theoretical gap, we propose an improved convergence analysis for the CBCD-type methods. In particular, we first show that for a family of quadratic minimization problems, the iteration complexity of the CBCD-type methods matches that of the GD methods in terms of dependency on $p$ (up to a $\log^2 p$ factor). Thus our complexity bounds are sharper than the existing bounds by at least a factor of $p/\log^2 p$. We also provide a lower bound to confirm that our improved complexity bounds are tight (up to a $\log^2 p$ factor) if the largest and smallest eigenvalues of the Hessian matrix do not scale with $p$. Finally, we generalize our analysis to other strongly convex minimization problems beyond quadratic ones.

I. INTRODUCTION

We consider a class of convex minimization problems in statistical machine learning:

$$x^* = \arg\min_{x \in \mathbb{R}^d} L(x) + R(x),$$

(1)

where $L(\cdot)$ is a twice differentiable loss function and $R(\cdot)$ is a possibly nonsmooth and strongly convex penalty function. Typical applications of (1) include elastic-net regression [1], ridge penalized logistic regression [2], support vector machine [3] and many other statistical machine learning problems [2]. The penalty function $R(x)$ in these

applications is block coordinate decomposable. For notational simplicity, we assume that there exists a partition of $d$ coordinates such that

$$x = [x_1^T, \ldots, x_p^T]^T \in \mathbb{R}^d,$$

where $x_j \in \mathbb{R}^{d_j}$, $d = \sum_{j=1}^p d_j$, and $d_j \ll p$. Then we can rewrite the objective function in (1) as

$$\mathcal{F}(x) = \mathcal{L}(x_1, \ldots, x_p) + \sum_{j=1}^p \mathcal{R}_j(x_j).$$

Many algorithms such as gradient decent (GD) methods [4], [5], cyclic block coordinate descent-type (CBCD-type) methods [6], [7], [8], [9], [10], [11], [12], [13], and alternating direction method of multipliers (ADMM, [14], [15], [16]) have been proposed to solve (1). Among these algorithms, the CBCD-type methods have been immensely successful [8], [17], [18], [19]. One popular instance of the CBCD-type methods is the cyclic block coordinate minimization (CBCM) method, which minimizes (1) with respect to a single block of variables while holding the rest fixed. Particularly, at the $(t+1)$-th iteration, given $x^{(t)}$, we choose to solve a collection of optimization problems: For $j = 1, \ldots, p$,

$$x_j^{(t+1)} = \arg\min_{x_j} \mathcal{L}\left(x_{1:(j-1)}, x_j, x_{(j+1):p}\right) + \mathcal{R}_j(x_j),$$

(2)

where $x_{1:(j-1)}^{(t+1)}$ and $x_{(j+1):p}^{(t)}$ are defined as

$$x_{1:(j-1)}^{(t+1)} = [x_1^{(t+1)\top}, \ldots, x_{j-1}^{(t+1)\top}]^\top$$

and

$$x_{(j+1):p}^{(t)} = [x_{j+1}^{(t)\top}, \ldots, x_p^{(t)\top}]^\top.$$

For some applications (e.g. elastic-net penalized linear regression), we can obtain a simple closed form solution to (2), but for many other applications (e.g. ridge-penalized logistic regression), (2) does not admit a closed form solution and requires more sophisticated optimization procedures.

A popular alternative is to solve a quadratic approximation of (2) using the cyclic block coordinate gradient descent (CBCGD) method. For notational simplicity, we denote the partial gradient $\nabla_{x_j} \mathcal{L}(x)$ by $\nabla_j \mathcal{L}(x)$. Then the CBCGD method solves a collection of optimization problems: For $j = 1, \ldots, p$,

$$x_j^{(t+1)} = \arg\min_{x_j} (x_j - x_j^{(t)})^\top \nabla_j \mathcal{L}\left(x_{1:(j-1)}^{(t+1)}, x_j, x_{(j+1):p}^{(t)}\right) + \frac{1}{2\eta_j} \|x_j - x_j^{(t)}\|^2 + \mathcal{R}_j(x_j),$$

(3)

where $\eta_j > 0$ is a step-size parameter for the $j$-th block.

There have been many results on iteration complexity of block coordinate descent-type (BCD-type) methods, but most of them focus on the randomized BCD-type methods, where blocks are randomly chosen with replacement in each iteration [20], [21], [22]. In contrast, existing literature on cyclic BCD-type methods is rather limited. Specifically, one line of research focuses on minimizing smooth objective functions, and has shown that given a pre-specified accuracy $\epsilon$ for the objective value, the CBCGD method attains linear iteration complexity of $O(\log(1/\epsilon))$ for minimizing smooth and strongly convex problems, and sublinear iteration complexity of $O(1/\epsilon)$ for smooth and nonstrongly convex problems [23]. Another line of research focuses on minimizing nonsmooth composite objective functions such as (1), and has shown that the CBCM and CBCGD methods attain sublinear iteration complexity of $O(1/\epsilon)$, when the objective function is nonstrongly convex [24].
Here we are interested in establishing an improved iteration complexity of the CBCM and CBCGD methods, when the nonsmooth composite objective function is strongly convex. Particularly, [23] has shown that for smooth minimization, the CBCGD method attains linear iteration complexity of

$$O\left(\mu^{-1}L^2p\log(1/\epsilon)\right),$$

where $L$ is the Lipschitz constant of the gradient mapping $\nabla L(x)$ and $\mu$ is the strongly convex coefficient of the objective function. However, such iteration complexity explicitly depends on $p$ (the number of blocks), and therefore is at least $p$ times worse than those of the gradient descent (GD) methods. To bridge this theoretical gap, we propose an improved convergence analysis for the CBCD-type methods. Specifically, we show that for a family of quadratic minimization problems, the iteration complexity of the CBCD-type methods matches that of the GD methods in term of dependency on $p$ (up to a $\log^2 p$ factor). More precisely, when $L(x)$ is quadratic, the iteration complexity of the CBCD-type methods is

$$O\left(\mu^{-1}L^2 \log^2 p \log(1/\epsilon)\right).$$

As can be seen easily, (5) is better than (4) by a factor of $p/\log^2 p$. We also provide a lower bound analysis that confirms that our improved iteration complexity is tight (up to a $\log^2 p$ factor) if the largest and smallest eigenvalues of the Hessian matrix do not scale with $p$. Finally, we generalize our analysis to other strongly convex minimization problems beyond quadratic ones. Specifically, for smooth minimization, the iteration complexity of the BCGD method is

$$O\left(\mu^{-1}p \log(1/\epsilon) \cdot \min\{L^2, p\}\right)$$

As can be seen easily, (6) is better than (4) when $L^2$ is significantly larger than $p$ (e.g. ill-conditioned problems); for more details refer to Table I.\footnote{When $R(\cdot)$ is nonsmooth, the optimization problem is actually solved by the cyclic block coordinate proximal gradient (CBCPGD) method. For notational convenience in this paper, however, we simply call it the CBCGD method.} It is worth mentioning that all the above results on the CBCD-type methods can be used to establish the iteration complexity for popular permuted BCM (PBCM) and permuted BCGD (PBCGD) methods, in which the blocks are randomly sampled without replacement.

\section*{II. Notations and Assumptions}

We start with some notations used in this paper. Given a vector $v = (v_1, \ldots, v_d)^T \in \mathbb{R}^d$, we define vector norms: $\|v\|_1 = \sum_j |v_j|$, $\|v\|^2 = \sum_j v_j^2$, and $\|v\|_\infty = \max_j |v_j|$. Let $\{A_1, \ldots, A_p\}$ be a partition of all $d$ coordinates with $|A_j| = d_j$ and $\sum_j d_j = d$. We use $v_j$ to denote the subvector of $v$ with all indices in $A_j$. Given a matrix $A \in \mathbb{R}^{d \times d}$, we use $\lambda_{\max}(A)$ and $\lambda_{\min}(A)$ to denote the largest and smallest eigenvalues of $A$. We denote $\|A\|$ as the spectral norm of $A$ (i.e., the largest singular value). We denote $\otimes$ and $\odot$ as the Kronecker product and Hadamard (entrywise) product for two matrices respectively.

Before we proceed with our convergence analysis, we introduce some assumptions on $L(\cdot)$ and $R(\cdot)$.\footnote{When $R(\cdot)$ is nonsmooth, the optimization problem is actually solved by the cyclic block coordinate proximal gradient (CBCPGD) method. For notational convenience in this paper, however, we simply call it the CBCGD method.}
Assumption 1. \( \mathcal{L}(\cdot) \) is convex, and its gradient mapping \( \nabla \mathcal{L}(\cdot) \) is Lipschitz continuous and also blockwise Lipschitz continuous, i.e., there exist positive constants \( L \) and \( L_j \)’s such that for any \( x, x' \in \mathbb{R}^d \) and \( j = 1, \ldots, p \), we have
\[
\| \nabla \mathcal{L}(x') - \nabla \mathcal{L}(x) \| \leq L \| x - x' \| \quad \text{and} \quad \| \nabla_j \mathcal{L} \left( x_{1:(j-1)}, x'_j, x_{(j+1):p} \right) - \nabla_j \mathcal{L}(x) \| \leq L_j \| x_j - x'_j \|.
\]
Moreover, we define \( L_{\max} = \max_j L_j \) and \( L_{\min} = \min_j L_j \).

Assumption 2. \( \mathcal{R}(\cdot) \) is strongly convex and also blockwise strongly convex, i.e., there exist positive constants \( \mu \) and \( \mu_j \)’s such that for any \( x, x' \in \mathbb{R}^d \) and \( j = 1, \ldots, p \), we have
\[
\mathcal{R}(x) \geq \mathcal{R}(x') + (x - x')^\top \xi' + \frac{\mu}{2} \| x - x' \|^2 \quad \text{and} \quad \mathcal{R}_j(x_j) \geq \mathcal{R}_j(x'_j) + (x_j - x'_j)^\top \xi'_j + \frac{\mu_j}{2} \| x_j - x'_j \|^2,
\]
for any \( \xi' \) in the sub-differential of \( \mathcal{R}(x') \), i.e. \( \xi' \in \partial \mathcal{R}(x') \). Moreover, we define \( \mu_{\min} = \min_j \mu_j \).

For notational simplicity, we define auxiliary variables
\[
I_{\min}^\mu = \min_j L_j + \mu_j \quad \text{and} \quad y^{(t,j)} = \left[ x_{1:(j-1)}, x_{j:p}^{(t-1)} + (x_{j:p}^{(t-1)})^\top \right]^\top, \ j = 1, \ldots, p.
\]

Our analysis considers \( L_{\min}, L_{\max}, L_{\min}^\mu, \mu_{\min}, \mu, \) and \( d_{\max} = \max_j d_j \) as constants, which do not scale with the block size \( p \).

### III. Improved Convergence Analysis

Our analysis consists of the following three steps:

1. Characterize the successive descent after each CBCD iteration;
(2) Characterize the gap towards the optimal objective value after each CBCD iteration;
(3) Combine (1) and (2) to establish the iteration complexity bound.

We present our analysis under different specifications on $\mathcal{L}(\cdot)$ and $\mathcal{R}(\cdot)$.

A. Quadratic Minimization

We first consider a scenario, where $\mathcal{L}(\cdot)$ is a quadratic function. Particularly, we solve

$$x^* = \arg\min_{x \in \mathbb{R}^d} \mathcal{L}(x) + \mathcal{R}(x) = \arg\min_{x_j \in \mathbb{R}^{d_j}} \frac{1}{2} \left\| \sum_{j=1}^{p} A_{*j} x_j - b \right\|^2 + \sum_{j=1}^{p} \mathcal{R}_j(x_j), \quad (7)$$

where $A_{*j} \in \mathbb{R}^{n \times d_j}$ for $j = 1, \ldots, p$. Typical applications of (7) in statistical machine learning include ridge regression, elastic-net penalized regression, and sparse additive regression.

We first characterize the successive descent of the CBCGD method.

**Lemma 1.** Suppose that Assumptions 1 and 2 hold. We choose $\eta_j = L_j$ for the CBCGD method. Then for all $t \geq 1$, we have

$$\mathcal{F}(x(t)) - \mathcal{F}(x(t+1)) \geq \frac{L_{\text{min}}}{2} \| x^{(t)} - x^{(t+1)} \|^2.$$  

**Proof.** At $t$-th iteration, there exists a $\xi_j^{(t+1)} \in \partial \mathcal{R}_j(x_j^{(t+1)})$ satisfying the optimality condition:

$$\nabla_j \mathcal{L}(y^{(t+1,j+1)}) + \eta_j (x_j^{(t+1)} - x_j^{(t)}) + \xi_j^{(t+1)} = 0. \quad (8)$$

Then by definition of CBCGD (3), we have

$$\mathcal{F}(y^{(t+1,j)}) - \mathcal{F}(y^{(t+1,j+1)}) = (x_j^{(t)} - x_j^{(t+1)})^\top \nabla_j \mathcal{L}(y^{(t+1,j+1)}) + \mathcal{R}_j(x_j^{(t)}) - \frac{L_j}{2} \| x_j^{(t+1)} - x_j^{(t)} \|^2 - \mathcal{R}_j(x_j^{(t+1)}). \quad (9)$$

By Assumptions 2, we have

$$\mathcal{R}_j(x_j^{(t)}) - \mathcal{R}_j(x_j^{(t+1)}) \geq (x_j^{(t)} - x_j^{(t+1)})^\top \xi_j^{(t+1)} + \frac{\mu_j}{2} \| x_j^{(t)} - x_j^{(t+1)} \|^2. \quad (10)$$

Combining (8), (9) and (10), we have

$$\mathcal{F}(y^{(t+1,j)}) - \mathcal{F}(y^{(t+1,j+1)}) \geq \frac{L_j + \mu_j}{2} \| x_j^{(t)} - x_j^{(t+1)} \|^2. \quad (11)$$

We complete the proof via summation of (11) over $j = 1, \ldots, p$. \hfill $\square$

Next, we characterize the gap towards the optimal objective value.

**Lemma 2.** Suppose that Assumptions 1 and 2 hold. Then for all $t \geq 1$, we have

$$\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \leq \frac{L^2 \log^2(2p \cdot d_{\text{max}})}{2\mu} \| x^{(t+1)} - x^{(t)} \|^2.$$  

Due to space limit, we only provide a proof sketch of Lemma 2, and the detailed proof can be found in Appendix VI-A.
Proof sketch. Since $\mathcal{L}(x)$ is quadratic, its second order Taylor expansion is tight, i.e.
\[
\mathcal{L}(x^*) = \mathcal{L}(x^{(t+1)}) + \langle \nabla \mathcal{L}(x^{(t+1)}), x^{(t+1)} - x^* \rangle + \frac{1}{2} \| A(x^{(t+1)} - x^*) \|^2,
\]
where $A = [A_1, \ldots, A_p] \in \mathbb{R}^{n \times d}$.

Consider matrices $\tilde{P}$ and $\tilde{A}$, defined as
\[
\tilde{P} = \left[ \begin{array}{cccc}
L_1 & 0 & 0 & \cdots & 0 \\
0 & L_2 & 0 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 0 & L_p
\end{array} \right] \in \mathbb{R}^{p \times p}, \quad \tilde{A} = \left[ \begin{array}{cccc}
A_{1+} & 0 & 0 & \cdots & 0 \\
0 & A_{2+} & 0 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 0 & A_{p+}
\end{array} \right] \in \mathbb{R}^{np \times d},
\]
which gives us the following inequality
\[
\tilde{P} \otimes I_m \succeq \tilde{A}^\top \tilde{A}.
\]
To characterize the gap towards the optimal objective value based on the strong convexity of $\mathcal{R}(\cdot)$, we exploit the tightness of the second order Taylor expansion of quadratic $\mathcal{L}(\cdot)$ in (12), the optimality condition of subproblems and a symmetrization technique involving Kronecker product, to show that
\[
\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \leq (x^{(t+1)} - x^{(t)})^\top B (x^{(t+1)} - x^*) - \frac{\mu}{2} \| x^{(t+1)} - x^* \|^2,
\]
where $B = (A^\top A - \tilde{A}^\top \tilde{A}) \odot D_d + \tilde{A}^\top \tilde{A} - \tilde{P} \otimes I_m$. By minimizing the R.H.S. of (14) w.r.t. $x^*$, we have
\[
\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \leq \frac{1}{2\mu} \| B (x^{(t+1)} - x^{(t)}) \|^2 \leq \frac{\lambda_{\max}^2(B)}{2\mu} \| x^{(t+1)} - x^{(t)} \|^2
\]
Finally, we obtain the desired result by bounding the spectral norm of $B$ using the result for triangular truncation operation, i.e.,
\[
\lambda_{\max}(B) \leq \lambda_{\max}(A^\top A - \tilde{A}^\top \tilde{A}) \log(2d) \leq L \log(2p \cdot d_{\max}),
\]
which completes the proof. \hfill \Box

Using Lemmas 1 and 2, we establish the iteration complexity bound of the CBCGD method for minimizing (7) in the next theorem.

**Theorem 3.** Suppose that Assumptions 1 and 2 hold. We choose $\eta_j = L_j$ for the CBCGD method. Given a pre-specified accuracy $\epsilon$ of the objective value, we need at most
\[
\left[ \frac{\mu L_{\min}^\mu + L^2 \log^2(2p \cdot d_{\max})}{\mu L_{\min}^\mu} \log \left( \frac{\mathcal{F}(x^{(0)}) - \mathcal{F}(x^*)}{\epsilon} \right) \right]
\]
iterations for the CBCGD method such that $\mathcal{F}(x^{(t)}) - \mathcal{F}(x^*) \leq \epsilon$

**Proof.** Combining Lemmas 1 and 2, we obtain
\[
\mathcal{F}(x^{(t)}) - \mathcal{F}(x^*) = [\mathcal{F}(x^{(t)}) - \mathcal{F}(x^{(t+1)})] + [\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*)]
\geq \frac{L_{\min}^\mu}{2} \| x^{(t)} - x^{(t+1)} \|^2 + [\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*)]
\geq \left( 1 + \frac{L_{\min}^\mu}{L^2 \log^2(2p \cdot d_{\max})} \right) \| \mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \|
\]
Recursively applying the above inequality for \( t \geq 1 \), we obtain

\[
\frac{F(x^{(t)}) - F(x^*)}{F(x^{(0)}) - F(x^*)} \leq \left(1 - \frac{\mu \mu_{\min}}{\mu \mu_{\min} + L^2 \log^2 (2p \cdot d_{\max})}\right)^t.
\]

To secure \( F(x^{(t)}) - F(x^*) \leq \epsilon \), we only need a large enough \( t \) such that

\[
\left(1 - \frac{\mu \mu_{\min}}{\mu \mu_{\min} + L^2 \log^2 (2p \cdot d_{\max})}\right)^t \left[F(x^{(0)}) - F(x^*)\right] \leq \epsilon.
\]

We complete the proof by the above inequality, and the basic inequality \( \kappa \geq \log^{-1} \left(\frac{\kappa}{\kappa - 1}\right) \).

As can be seen in Theorem 3, the iteration complexity depends on \( p \) only in the order of \( \log^2 p \), which is generally mild in practice. The iteration complexity of the CBCM method can be established in a similar manner.

**Theorem 4.** Suppose that Assumptions 1 and 2 hold. Given a pre-specified accuracy \( \epsilon \), we need at most

\[
\left[\frac{\mu \mu_{\min} + 4L^2 \log^2 (2p \cdot d_{\max})}{\mu \mu_{\min}} \log \left(\frac{F(x^{(0)}) - F(x^*)}{\epsilon}\right)\right]
\]

iterations for the CBCM method such that \( F(x^{(t)}) - F(x^*) \leq \epsilon \)

Theorem 4 establishes that the iteration complexity of the CBCM method matches that of the CBCGD method. To the best of our knowledge, Theorems 3 and 4 are the sharpest iteration complexity analysis of the CBCD-type methods for minimizing (7). Due to space limitations, we defer the proof of Theorem 4 to Appendix VI-B.

**B. The Tightness of the Iteration Complexity for Quadratic Problems**

We next provide an example to establish the tightness of the above result. We consider the following optimization problem

\[
\min_x \mathcal{H}(x) := \|Bx\|^2,
\]

where \( B \in \mathbb{R}^{p \times p} \) is a tridiagonal Toeplich matrix defined as follows:

\[
B = \begin{bmatrix}
3 & 1 & 0 & 0 & \ldots & 0 & 0 & 0 \\
1 & 3 & 1 & 0 & \ldots & 0 & 0 & 0 \\
0 & 1 & 3 & 1 & \ldots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \ldots & 1 & 3 & 1 \\
0 & 0 & 0 & 0 & \ldots & 0 & 1 & 3
\end{bmatrix}.
\]

Note that the minimizer to (15) is \( x^* = [0, 0, \ldots, 0]^\top \), and the eigenvalues of \( B \) are given by \( 3 + 2 \cos(i\pi/(j + 1)) \) for \( j = 1, \ldots, p \). Since the Hessian matrix of (15) is \( 2B^\top B \), we have

\[
L = \lambda_{\max}(2B^\top B) \leq 50, \mu = \lambda_{\min}(2B^\top B) \geq 2, \mu_{\min} = 10.
\]
Clearly, for this problem the largest and smallest eigenvalues of the Hessian matrix, as well as \( L/\gamma \) do not scale with \( p \). We consider each coordinate \( x_j \in \mathbb{R} \) as a block. Then the problem can be rewritten as \( \min \| \sum_{j=1}^{p} B_{*j} x_j \| \), where \( B_{*j} \) denotes the \( j \)-th column of \( B \). Given an initial solution \( x^{(0)} \), we can show that \( x^{(1)} \) is generated by

\[
x_1^{(1)} = -\frac{1}{4} \left( 4x_2^{(0)} + 2x_3^{(0)} \right), \quad (16)
\]

\[
x_2^{(1)} = -\frac{1}{5} \left( 4x_1^{(1)} + 4x_3^{(0)} + 4x_4^{(0)} \right), \quad (17)
\]

\[
x_3^{(1)} = -\frac{1}{5} \left( x_1^{(1)} + 4x_2^{(1)} + x_4^{(0)} + x_5^{(0)} \right), \quad (18)
\]

\[
x_2^{(1)} = -\frac{1}{5} \left( x_1^{(1)} + 4x_2^{(1)} + x_4^{(0)} + x_5^{(0)} \right), \quad (19)
\]

\[
x_3^{(1)} = -\frac{1}{5} \left( x_1^{(1)} + 4x_2^{(1)} + x_4^{(0)} + x_5^{(0)} \right), \quad (20)
\]

\[
x_x^{(1)} = -\frac{1}{5} \left( x_1^{(1)} + 4x_2^{(1)} + x_4^{(0)} + x_5^{(0)} \right), \quad (21)
\]

Now we choose the initial solution

\[ x^{(0)} = \left[ 1, \frac{9}{32}, \frac{7}{8}, 1, \ldots, 1, 1 \right]^T. \]

Then by (16)–(21), we obtain

\[ x^{(1)} = \left[ -\frac{1}{2}, -\frac{1}{2}, \ldots, -\frac{1}{2}, -\frac{3}{10}, -\frac{17}{40} \right], \]

which yields

\[ \mathcal{H}(x^{(1)}) - \mathcal{H}(x^*) \geq \frac{25}{4} (p - 3), \]

\[ \| x^{(0)} - x^* \|^2 \leq p - 2 + \left( \frac{9}{32} \right)^2 + \left( \frac{7}{8} \right)^2 \leq p - 1. \]

Therefore, we have

\[ \frac{\mathcal{H}(x^{(1)}) - \mathcal{H}(x^*)}{\| x^{(0)} - x^* \|^2} \geq \frac{25(p - 3)}{4p} \geq \frac{22}{4}. \]

This implies that when the largest and smallest eigenvalues of the Hessian matrix do not scale with \( p \) (the number of blocks), the iteration complexity is independent of \( p \), and cannot be further improved.

**C. General Smooth Minimization**

We next consider general strongly convex smooth minimization, which includes \([23]\) as a special case. Here we require \( \mathcal{R}(x) \) to be smooth and strongly convex.

**Assumption 3.** \( \mathcal{R}(\cdot) \) is smooth and also blockwise smooth, i.e., there exist positive constants \( \beta \) and \( \beta_j \)'s such that for \( x, x' \in \mathbb{R}^d \) and \( j = 1, \ldots, p \), we have

\[
\mathcal{R}(x) \leq \mathcal{R}(x') + (x - x')^T \nabla \mathcal{R}(x') + \frac{\beta}{2} \| x - x' \|^2 \] \text{ and }

\[
\mathcal{R}_j(x_j) \leq \mathcal{R}_j(x_j') + (x_j - x_j')^T \nabla_j \mathcal{R}(x') + \frac{\beta_j}{2} \| x_j - x_j' \|^2.
\]

Moreover, we define \( \beta_{\text{max}} = \max_j \beta_j \).
Moreover, we assume that the Hessian matrix $H$ of the objective function $F$ exists, which is denoted as $H_{ij}(x) = \frac{\partial^2 F(x)}{\partial x_i \partial x_j}$.

Since the objective function is globally smooth, the CBCGD method can directly take: For $j = 1, \ldots, p$,

$$x_j^{(t+1)} = x_j^{(t)} - \eta_j \left( \nabla_j L_j^{(t+1,j)} + \nabla_j R_j^{(x_j^{(t)})} \right),$$

where $\eta_j > 0$ is a step-size parameter for the $j$-th block.

Typical applications of the general strongly convex smooth minimization in statistical machine learning includes ridge penalized logistic regression, and ridge penalized multinomial regression. It is worth mentioning that our analysis for general case is applicable to smooth quadratic minimization, but is very different from the analysis in previous sections for quadratic minimization. For simplicity, we only consider $d_{\text{max}} = d_1 = \ldots = d_p = 1$, and leave the generalization to $d_{\text{max}} > 1$ to future work.

We first characterize the successive descent after each coordinate gradient descent (CGD) iteration.

**Lemma 5.** Suppose that Assumption 1 and 3 hold. We choose $\eta_j = L_j + \beta_j$ for the CBCGD method. Then for all $t \geq 1$, there exists $z^{(t,j)}$ in the line segment of $(x_j^{(t)}, y^{(t,j)})$ for each $j \in \{1, \ldots, p\}$ such that

$$F(x_j^{(t)}) - F(x_j^{(t+1)}) \geq \frac{\| \nabla F(x_j^{(t)}) \|^2}{2 \left( L_{\beta}^{\text{max}} + \| H \|^2 / L_{\beta}^{\text{min}} \right)},$$

where $H$ is defined as

$$H \equiv \begin{bmatrix}
0 & 0 & 0 & \ldots & 0 & 0 \\
H_{21} & 0 & 0 & \ldots & 0 & 0 \\
H_{31} & H_{32} & 0 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
H_{p1} & H_{p2} & H_{p3} & \ldots & H_{p,p-1} & 0
\end{bmatrix},$$

with $H_{j,i} \equiv H_{j,i}(z^{(t,j)}) = \frac{\partial F(z^{(t,j)})}{\partial x_i \partial x_j}$, and $L_{\beta}^{\text{min}}$ and $L_{\beta}^{\text{max}}$ defined as

$$L_{\beta}^{\text{min}} = \min\{L_j + \mu_j, j = 1, \ldots, p\},$$

$$L_{\beta}^{\text{max}} = \max\{L_j + \mu_j, j = 1, \ldots, p\}.$$
where $\tilde{H}$ is a matrix with $\tilde{H}_{jj} = \sqrt{L_j^2}$ and $\tilde{H}_{ji} = H_{ji}/\sqrt{L_j^2}$. The desired result can be obtained by further providing a upper bound of $\|\tilde{H}\|^2$ as

$$\|\tilde{H}\|^2 \leq 2 \left( \frac{L_{j_{\text{max}}}^2 + \|H\|^2_{\text{max}}}{L_{j_{\text{min}}}^2} \right),$$

which completes the proof by combining the results above.

We now characterize the gap towards the optimal objective value after each CGD iteration.

**Lemma 6.** Suppose that Assumption 1 and 2 hold. Then for all $t \geq 1$, we have

$$F(x^{(t)}) - F(x^*) \leq \frac{\|\nabla F(x^{(t)})\|^2}{2\mu}.$$

**Proof.** From the convexity of $L(\cdot)$ and strong convexity of $R(\cdot)$, we have

$$F(x^{(t)}) - F(x^*) \leq (x^{(t)} - x^*)^\top \nabla F(x^{(t)}) - \frac{\mu}{2} \|x^{(t)} - x^*\|^2.$$

Minimizing the right hand side over $x^*$, we have $x^* = x^{(t)} - \frac{\nabla F(x^{(t)})}{\mu}$ and the desired result.

Combining the two lemmas above, we establish the iteration complexity bound of CGD.

**Theorem 7.** Suppose that Assumption 1, 2 and 3 hold. We choose $\eta_j = L_j + \beta_j$. Then given a pre-specified accuracy $\epsilon$, we need at most

$$\left\lfloor \frac{\mu + L_{\text{max}} + \min\{pL^2_2, p^2L_{\text{max}}^2\}}{L_{\text{min}}} \log \left( \frac{\|F(x^{(0)}) - F(x^*)\|}{\epsilon} \right) \right\rfloor$$

iterations such that $F(x^{(t)}) - F(x^*) \leq \epsilon$.

**Proof.** We first bound $\|H\|$. From the fact that $|H_{ji}| \leq \sqrt{L_j L_i}$, we have

$$\|H\|^2 \leq \|H\|_F^2 = \sum_{j=2}^{p} \left( \sum_{i=1}^{j-1} |H_{ji}|^2 \right) \leq \sum_{j=2}^{p} \sum_{i=1}^{j-1} L_j L_i \leq p^2L_{\text{max}}^2.$$

An alternative bound is

$$\|H\|^2 \leq \|H\|_F^2 = \sum_{j=1}^{p} \left( \sum_{i=1}^{p} H_{ji}^2 \right) \leq \sum_{j=1}^{p} L^2 \leq pL^2.$$

Thus we have $\|H\| \leq \min\{p^2L_{\text{max}}^2, pL^2\}$. Then we only need to combine Lemmas 5 and 6, and follow similar lines to the proof of Theorem 3 to complete the proof.

As can be seen from Theorem 7, the established iteration complexity bound is shaper than that in [23] for ill-conditioned optimization problems, in which we often observe $L^2 \gg p$. 

\[\text{January 16, 2016 DRAFT}\]
D. General Nonsmooth Minimization

We provide an iteration complexity bound of the CBCM and CBCGD methods for a general $\mathcal{L}(\cdot)$ and a nonsmooth $\mathcal{R}(\cdot)$. Due to space limitations, we simply state the main result here; see Appendix VI-D for a detailed proof.

**Theorem 8.** Suppose that Assumptions 1 and 2 hold. We choose $\eta_j = L_j$ for the CBCGD method. Then given a pre-specified accuracy $\epsilon$ of the objective value, we need at most

$$\left\lceil \frac{\mu L_{\min}^p + 4pL^2}{\mu L_{\min}^p} \log \left( \frac{\mathcal{F}(x^{(0)}) - \mathcal{F}(x^*)}{\epsilon} \right) \right\rceil$$

iterations for the CBCGD method and at most

$$\left\lceil \frac{\mu\mu_{\min} + 4\sigma^2}{\mu\mu_{\min}} \log \left( \frac{\mathcal{F}(x^{(0)}) - \mathcal{F}(x^*)}{\epsilon} \right) \right\rceil$$

iterations for the CBCM method to guarantee $\mathcal{F}(x^{(t)}) - \mathcal{F}(x^*) \leq \epsilon$.

Theorem 8 is a general result for general nonsmooth minimization. In contrast, [23] only covers general smooth minimization.

E. Extensions to Nonstrongly Convex Minimization

For nonstrongly convex minimization, we only need to add a strongly convex perturbation to the objective function

$$\tilde{x} = \arg\min \ F(x) + \frac{\sigma}{2} \|x\|^2,$$

(23)

where $\sigma > 0$ is a perturbation parameter. Then, the results above can be used to analyze the CBCD-type methods for minimizing (23). Eventually, by setting $\sigma$ as a reasonable small value, we can establish $O(1/\epsilon)$-type iteration complexity bounds up to a $\log(1/\epsilon)$ factor. See [25] for more details.

IV. Numerical Results

![Comparison among different methods under different settings. “RBCGD” and “PBCGD” denote the randomized BCD-type and permuted BCD-type methods respectively. The vertical axis corresponds to the gap towards the optimal objective value, $\log[\mathcal{F}(x) - \mathcal{F}(x^*)]$; the horizontal axis corresponds to the number of passes over $p$ blocks of coordinates. Though all methods attain linear iteration complexity, their empirical behaviors are different from each others. Note that in plot (b) the curves for the CBCGD method and the RBCGD methods overlap.](image)
We consider two typical statistical machine learning problems $\Sigma$ as examples to illustrate our analysis.

(I) Elastic-net Penalized Linear Regression: Let $A \in \mathbb{R}^{n \times d}$ be the design matrix, and $b \in \mathbb{R}^n$ be the response vector. We solve the following optimization problem

$$\min_{x \in \mathbb{R}^d} \frac{1}{2n} \|b - Ax\|^2 + \lambda_1 \|x\|^2 + \lambda_2 \|x\|_1,$$

where $\lambda$ is the regularization parameter. We set $n = 10,000$ and $d = 20,000$. We simply treat each coordinate as a block (i.e., $d_{\text{max}} = 1$). Each row of $A$ is independently sampled from a 20,000-dimensional Gaussian distribution with mean 0 and covariance matrix $\Sigma$. We randomly select 2,500 entries of $x$, each of which is independently sampled from a uniform distribution over support $(-2, +2)$. The response vector $b$ is generated by the linear model $b = Ax + \epsilon$, where $\epsilon$ is sampled from an $n$-variate Gaussian distribution $N(0, I_n)$. We set $\lambda_1 = 1/\sqrt{n} = 0.01$ and $\lambda_2 = \sqrt{\log d/n} \approx 0.0315$. We normalize $A$ to have $\|A_{\ast j}\| = \sqrt{n}$ for $j = 1, \ldots, d$, where $A_{\ast j}$ denotes the $j$-th column of $A$. For the BCGD method, we choose $\eta_j = 1$. For the gradient descent method, we either choose $\eta = \lambda_{\text{max}} \left(\frac{1}{\pi} A^\top A\right)$, or adaptively select $\eta$ by backtracking line search.

(II) Ridge Penalized Logistic Regression: We solve the following optimization problem

$$\min_{x \in \mathbb{R}^d} \frac{1}{n} \sum_{i=1}^n \left[\log(1 + \exp(x^\top A_{i\ast})) - b_i x^\top A_{i\ast}\right] + \lambda \|x\|^2.$$

We generate the design matrix $A$ and regression coefficient vector $x$ using the same scheme as sparse linear regression. Again we treat each coordinate as a block (i.e., $d_{\text{max}} = 1$). The response $b = [b_1, \ldots, b_n]^\top$ is generated by the logistic model $b_i = \text{Bernoulli}(1 + \exp(-x^\top A_{i\ast})^{-1})$. We set $\lambda = \sqrt{1/n}$. For the BCGD method, we choose $\eta_j = \frac{1}{4}$. For gradient descent methods, we choose either the step size $\eta = \frac{1}{4} \lambda_{\text{max}} \left(\frac{1}{\pi} A^\top A\right)$ or adaptively select $\eta$ by backtracking line search.

We evaluate the computational performance using the number of passes over $p$ blocks of coordinates (normalized iteration complexity). For the CBCGD method, we count one iteration as one pass (all $p$ blocks). For the randomized BCGD (RBCGD) method, we count $p$ iterations as one pass (since it only updates one block in each iteration). Besides the CBCGD and RBCGD methods, we also consider a variant of the CBCGD method named the permuted BCGD (PBCGD) method, which randomly permutes all indices for the $p$ blocks in each iteration. Since the RBCGD and PBCGD methods are inherently stochastic, we report the objective values averaged over 20 different runs. Moreover, for the RBCGD method, the block of coordinates is selected uniformly at random in each iteration.

We consider three different settings: Setting (I) is the sparse linear regression, where the covariance matrix for generating the design matrix has $\Sigma_{jj} = 1$ and $\Sigma_{jk} = 0.5$ for any $k \neq j$; Setting (II) is the sparse linear regression, where the covariance matrix for generating the design matrix has $\Sigma_{jk} = 0.5^{j-k}$ for any $j$ and $k$; Setting (III) is the sparse logistic regression, where the covariance matrix for generating the design matrix is the same as Setting (II). Note that the condition number of the Hessian matrix depends on $\Sigma$. Setting (I) tends to yield a badly conditioned Hessian matrix whereas Settings (II) and (III) tend to yield well-conditioned Hessian matrices.

Figure 1 plots the gap between the objective value and the optimal as a function of number of passes for different methods. Our empirical findings can be summarized as follows: (1) All BCD-type methods attain better performance than the GD methods; (2) When the Hessian matrix is badly conditioned (i.e., in Setting (I)), the CBCGD performs
worse than the RBCGD and PBCGD methods. (3) When the Hessian matrix is well conditioned (e.g. in Settings (II) and (III)), all three BCD-type methods attain good performance, and the CBCGD method slightly outperforms the PBCGD method; (4) The CBCGD method outperforms the RBCGD method in Setting (III).

V. DISCUSSIONS

Existing literature has established an iteration complexity of \( O(\mu^{-1}L \cdot \log(1/\epsilon)) \) for the gradient descent methods when solving strongly convex composite problems. However, our analysis shows that the CBCD-type methods only attain an iteration complexity of \( O(\mu^{-1}pL^2 \cdot \log(1/\epsilon)) \). Even though our analysis further shows that the iteration complexity of the CBCD-type methods can be further improved to \( O(\mu^{-1} \log^2 pL^2 \cdot \log(1/\epsilon)) \) for a quadratic \( \mathcal{L}(\cdot) \), there still exists a gap of factor \( L \log^2 p \). As our numerical experiments show, however, the CBCD-type methods can actually attain a better computational performance than the gradient methods regardless of whether \( \mathcal{L}(\cdot) \) is quadratic or not, thereby suggesting that perhaps there is still room for improvement in the iteration complexity analysis of the CBCD-type methods.

It is also worth mentioning that though some literature claims that the CBCD-type methods works as well as the randomized BCD-type methods in practice, there do exist some counter examples, e.g. our experiment in Setting (I), where the CBCD-type methods fail significantly. This suggests that the CBCD-type methods do have some possible disadvantages in practice. To the best of our knowledge, we are not aware of any similar experimental results reported in existing literature.

Furthermore, our numerical results show that the permuted BCD-type methods, which can be viewed as a hybrid of the cyclic and the randomized BCD-type (RBCD-type) methods, has a stable performance irrespective of the problem being well conditioned or not. But to the best of our knowledge, no iteration complexity result has been established for the permuted BCD-type (PBCD-type) methods. We leave these problems for future investigation.

VI. APPENDIX

A. Proof of Lemma 2

For simplicity, we assume that $d_1 = \ldots = d_p = m = d/p$. For any $s \in \mathbb{Z}^+$, we define the lower triangular matrix $D_s \in \mathbb{R}^{s \times s}$ as

$$
D_s = \begin{bmatrix}
1 & 0 & 0 & \ldots & 0 & 0 \\
1 & 1 & 0 & \ldots & 0 & 0 \\
1 & 1 & 1 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
1 & 1 & 1 & \ldots & 1 & 1
\end{bmatrix}
$$

By the definition of $L_j$, we have

$$L_j \geq \lambda_{\text{max}}(A_j^\top A_j), \forall j.$$

Then we have

$$
F(x^{(t+1)}) - F(x^{*})
\leq (\nabla L(x^{(t+1)}), x^{(t+1)} - x^{*}) + R(x^{(t+1)}) - R(x^{*})
\leq (\nabla L(x^{(t+1)}), x^{(t+1)} - x^{*}) + \xi^{(t+1)}, x^{(t+1)} - x^{*} - \frac{\mu}{2} \|x^{(t+1)} - x^{*}\|^2
\leq \sum_{j=1}^p \left( \sum_{k \geq j} A_k(x^{(t+1)}_k - x^{(t)}_k), A_j(x^{(t+1)}_j - x^{*}_j) \right) - (x^{(t+1)} - x^{(t)})^\top (\tilde{P} \otimes I_m)(x^{(t+1)} - x^{*}) - \frac{\mu}{2} \|x^{(t+1)} - x^{*}\|^2
\leq (x^{(t+1)} - x^{(t)})^\top \tilde{A}^\top (D_p \otimes I_m) \tilde{A}(x^{(t+1)} - x^{*}) - (x^{(t+1)} - x^{(t)})^\top (\tilde{P} \otimes I_m)(x^{(t+1)} - x^{*}) - \frac{\mu}{2} \|x^{(t+1)} - x^{*}\|^2
\leq (x^{(t+1)} - x^{(t)})^\top \left( \tilde{A}^\top (D_p \otimes I_m) \tilde{A} \otimes D_d + \tilde{A}^\top \tilde{A} \otimes \tilde{P} \otimes I_m \right)(x^{(t+1)} - x^{*}) - \frac{\mu}{2} \|x^{(t+1)} - x^{*}\|^2,
$$

where (i) is from (12), (ii) is from Assumption 2, (iii) is from the optimality condition to the subproblem associated with $x_j$,

$$
\langle \nabla_j L(x^{(t)}), L_j(x^{(t+1)}_j - x^{(t)}_j) + \xi^{(t+1)}_j, x_j - x^{(t+1)}_j \rangle \geq 0 \text{ for any } x_j \in \mathbb{R}^m,
$$

and (iv) comes from the fact that

$$
\tilde{A}^\top (D_p \otimes I_m) \tilde{A} = \left( A^\top A - \tilde{A}^\top \tilde{A} \right) \otimes D_d + \tilde{A}^\top \tilde{A},
$$

where $\otimes$ denotes the Hadamard product and $1_n \in \mathbb{R}^{n \times n}$ is a matrix with all entries as 1.

Let us define

$$
B = \left( A^\top A - \tilde{A}^\top \tilde{A} \right) \otimes D_d + \tilde{A}^\top \tilde{A} \otimes \tilde{P} \otimes I_m,
$$
then we have
\[ F(x^{t+1}) - F(x^*) \leq (x^{t+1} - x^{(t)})^\top B(x^{t+1} - x^*) - \frac{\mu}{2} ||x^{t+1} - x^*||^2, \] (24)

Maximizing R.H.S. of the above inequality over \( x^* \), we obtain
\[ -\mu(x^* - x^{(t+1)}) - B^\top (x^{t+1} - x^{(t)}) = 0. \]
which implies
\[ x^* = -\frac{B^\top (x^{t+1} - x^{(t)})}{\mu} + x^{(t+1)}. \] (25)

Plugging (25) into (24), we obtain
\[ F(x^{t+1}) - F(x^*) \leq \frac{1}{2\mu} \|B(x^{t+1} - x^{(t)})\|^2 \leq \frac{\lambda_{\max}^2(B)}{2\mu} \|x^{t+1} - x^{(t)}\|^2 \]
\[ \leq \frac{\lambda_{\max}^2 \left( A^\top A - \tilde{A}^\top \tilde{A} \right)}{2\mu} \|x^{t+1} - x^{(t)}\|^2 \]
\[ \leq \frac{\lambda_{\max}^2 \left( A^\top A - \tilde{A}^\top \tilde{A} \right) 1 + \frac{1}{\pi} + \frac{\log(d)}{\pi}}{2\mu} \|x^{t+1} - x^{(t)}\|^2 \]
\[ \leq \frac{\lambda_{\max}^2 \left( A^\top A - \tilde{A}^\top \tilde{A} \right) \log^2(2d)}{2\mu} \|x^{t+1} - x^{(t)}\|^2 \]
\[ \leq \frac{L^2 \log^2(2d)}{2\mu} \|x^{t+1} - x^{(t)}\|^2, \]
where (i) comes from (13), which indicates that \( \lambda_{\max}(\tilde{A}^\top \tilde{A} - \tilde{P} \otimes I_m) \leq 0 \), (iii) is true if \( d \geq 3 \), and (iv) comes from \( d \leq p \cdot d_{\max} \) and the fact that
\[ \lambda_{\max} \left( A^\top A - \tilde{A}^\top \tilde{A} \right) \leq \lambda_{\max} \left( A^\top A \right) + \lambda_{\max} \left( -\tilde{A}^\top \tilde{A} \right) \leq \lambda_{\max} \left( A^\top A \right) \leq L. \]

Inequality (ii) follows from the result on the spectral norm of the triangular truncation operator in [26]. More specifically, let us define
\[ L_d = \max \left\{ \frac{\|A \odot D_d\|}{\|A\|} : A \in \mathbb{R}^{d \times d}, A \neq 0 \right\}. \]
Then we have
\[ \left| \frac{L_d}{\log d} - \frac{1}{\pi} \right| \leq \frac{(1 + \frac{1}{\pi})}{\log d}. \]
The final claim holds by the fact that \( d \leq p \cdot d_{\max} \).

**B. Proof of Theorem 4**

The overall proof also consists of three major steps: (i) successive descent, (ii) gap towards the optimal objective value, and (iii) iteration complexity.

**Successive Descent:** At \( t \)-th iteration, there exists a \( \xi_j^{(t+1)} \in \partial R_j(x_j^{(t+1)}) \) satisfying the optimality condition:
\[ \nabla_j L(y^{(t+1,j+1)}) + \xi_j^{(t+1)} = 0. \] (26)
Then we have

\[
\mathcal{F}(y^{(t+1,j)}) - \mathcal{F}(y^{(t+1,j+1)}) \geq (x_j^{(t)} - x_j^{(t+1)})^\top \nabla_j \mathcal{L}(y^{(t+1,j+1)}) + \mathcal{R}_j(x_j^{(t)}) - \mathcal{R}_j(x_j^{(t+1)}) \\
\geq \left(\nabla_j \mathcal{L}(y^{(t+1,j+1)}) + \xi_j^{(t+1)}\right)^\top (x_j^{(t)} - x_j^{(t+1)}) + \frac{\mu_j}{2} \|x_j^{(t)} - x_j^{(t+1)}\|^2
\]

\[
\geq \frac{\mu_j}{2} \|x_j^{(t)} - x_j^{(t+1)}\|^2,
\]

(27)

where (i) is from the convexity of \(\mathcal{L}(\cdot)\), (ii) is from Assumptions 2 and \(\eta_j \geq L_j\), and (iii) is from (8). By summation of (11) over \(j = 1, \ldots, p\), we have

\[
\mathcal{F}(x^{(t)}) - \mathcal{F}(x^{(t+1)}) \geq \frac{\mu_{\min}}{2} \|x^{(t)} - x^{(t+1)}\|^2.
\]

**Gap towards the Optimal Objective Value:** The proof follows the same arguments with the proof of Lemma 2, with a few differences.

First, with the optimality condition to the subproblem associated with \(x_j\),

\[
\langle \nabla_j \mathcal{L}(x^{(t)}) + \xi_j^{(t+1)}, x_j - x_j^{(t+1)} \rangle \geq 0 \text{ for any } x_j \in \mathbb{R}^m,
\]

we have

\[
\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \leq (x^{(t+1)} - x^{(t)})^\top B(x^{(t+1)} - x^*) - \frac{\mu}{2} \|x^{(t+1)} - x^*\|^2,
\]

where \(B = \left(A^\top A - \tilde{A}^\top \tilde{A}\right) \odot D_d + \tilde{A}^\top \tilde{A}\).

Then, using the same technique to bound the eigenvalues for matrices with Hadamard product, we have

\[
\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \leq \frac{L^2 \log^2(2d) + L_{\max}^2 \|x^{(t+1)} - x^{(t)}\|^2}{\mu} \leq \frac{2L^2 \log^2(2d)}{\mu} \|x^{(t+1)} - x^{(t)}\|^2.
\]

**Iteration Complexity:** The analysis follows from that of Theorem 3.

**C. Proof of Lemma 5**

We have that \(y^{(t,j)}\) and \(y^{(t,k+1)}\) only differ at the \(k\)-th coordinate, and \(\nabla_j \mathcal{F}(y^{(t,k)})\) has Lipschitz gradient with Lipschitz constant \(F_j\), which implied

\[
\mathcal{F}(y^{(t,j+1)}) \leq \mathcal{F}(y^{(t,j)}) + (y^{(t,j+1)} - y^+)^\top \nabla_j \mathcal{F}(y^{(t,j)}) + \frac{F_j}{2} \|y^{(t,j+1)} - y^{(t,j)}\|^2
\]

\[
\begin{aligned}
&\overset{(i)}{=} \mathcal{F}(y^{(t,j)}) - \frac{2L_j^2 - F_j}{2(L_j^2)^2} \|\nabla_j \mathcal{F}(y^{(t,j)})\|^2 \overset{(ii)}{\leq} \mathcal{F}(y^{(t,j)}) - \frac{1}{2L_j^2} \|\nabla_j \mathcal{F}(y^{(t,j)})\|^2,
\end{aligned}
\]

where (i) is from that \(x_j^{(t+1)} = x_j^{(t)} - \nabla_j \mathcal{F}(y^{(t,j)}) L_j^\beta\), and (ii) is from the fact that \(L_j^\beta \geq F_j\). Then the decrease of the objective is

\[
\mathcal{F}(x^{(t)}) - \mathcal{F}(x^{(t+1)}) = \sum_{k=1}^{p} \mathcal{F}(y^{(t,j)}) - \mathcal{F}(y^{(t,j+1)}) \geq \sum_{k=1}^{p} \frac{1}{2L_j^\beta} \|\nabla_j \mathcal{F}(y^{(t,j)})\|^2.
\]

(28)
There exists $z^{(t,j)}$ such that

$$\nabla_j F(x^{(t)}) = \nabla_j F(x^{(t)}) - \nabla_j F(y^{(t,j)}) + \nabla_j F(y^{(t,j)})$$

$$\overset{(i)}{=} \nabla(\nabla_j F(z^{(t,j)})) - \nabla_j F(y^{(t,j)}) + \nabla_j F(y^{(t,j)})$$

$$= \left[ \frac{\partial F(z^{(t,j)})}{\partial z_1}, \ldots, \frac{\partial F(z^{(t,j)})}{\partial z_{j-1}}, 0, \ldots, 0 \right] \left[ \begin{array}{cccc} \frac{x_1^{(t)} - x_1^{(t+1)}}{L_1^\beta}, & \ldots, & \frac{x_{j-1}^{(t)} - x_{j-1}^{(t+1)}}{L_{j-1}^\beta}, & 0, \ldots, 0 \end{array} \right]^\top + \nabla_j F(y^{(t,j)})$$

$$= \left[ \frac{H_{1}}{\sqrt{L_1^\beta}}, \ldots, \frac{H_{j-1}}{\sqrt{L_{j-1}^\beta}}, 0, \ldots, 0 \right] \left[ \begin{array}{cccc} \frac{x_1^{(t)} - x_1^{(t+1)}}{L_1^\beta}, & \ldots, & \frac{x_{j-1}^{(t)} - x_{j-1}^{(t+1)}}{L_{j-1}^\beta}, & 0, \ldots, 0 \end{array} \right]^\top + \nabla_j F(y^{(t,j)})$$

$$= \left[ \frac{H_{1}}{\sqrt{L_1^\beta}}, \ldots, \frac{H_{j-1}}{\sqrt{L_{j-1}^\beta}}, \frac{L_j^\beta}{\sqrt{L_j^\beta}}, 0, \ldots, 0 \right] \left[ \begin{array}{cccc} \nabla_1 F(y^{(t,1)}), & \ldots, & \nabla_p F(y^{(t,p)}) \end{array} \right]^\top$$

$$= h_j^\top f$$

where (i) is from the mean-value theorem, $h_j = \left[ \frac{H_{1}}{\sqrt{L_1^\beta}}, \ldots, \frac{H_{j-1}}{\sqrt{L_{j-1}^\beta}}, \frac{L_j^\beta}{\sqrt{L_j^\beta}}, 0, \ldots, 0 \right]$ and $f = \left[ \frac{\nabla_1 F(y^{(t,1)})}{\sqrt{L_1^\beta}}, \ldots, \frac{\nabla_p F(y^{(t,p)})}{\sqrt{L_p^\beta}} \right]$.

Let $\bar{H}$ be

$$\bar{H} = \begin{bmatrix} h_1^\top \\
\vdots \\
h_p^\top \end{bmatrix} = \begin{bmatrix} \sqrt{L_1^2} & 0 & 0 & \ldots & 0 & 0 \\
\frac{H_{11}(z^{(t,2)})}{\sqrt{L_2^\beta}} & \sqrt{L_2^\beta} & 0 & \ldots & 0 & 0 \\
\frac{H_{12}(z^{(t,3)})}{\sqrt{L_3^\beta}} & \frac{H_{22}(z^{(t,3)})}{\sqrt{L_3^\beta}} & 0 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \ddots & \ddots \\
\frac{H_{1p}(z^{(t,p)})}{\sqrt{L_p^\beta}} & \frac{H_{2p}(z^{(t,p)})}{\sqrt{L_p^\beta}} & \frac{H_{3p}(z^{(t,p)})}{\sqrt{L_p^\beta}} & \ldots & \frac{H_{p-1}(z^{(t,p)})}{\sqrt{L_{p-1}^\beta}} & \sqrt{L_p^\beta} \end{bmatrix}$$

Then we have

$$\|\nabla F(x^{(t)})\|^2 = \sum_{j=1}^P \|\nabla_j F(x^{(t)})\|^2 = \sum_{j=1}^P \|h_j^\top f\|^2 = \|\bar{H} f\|^2 \leq \|\bar{H}\|^2 \|f\|^2 = \|H\|^2 \sum_{k=1}^P \frac{1}{2L_j^\beta} \|\nabla_j F(y^{(t,j)})\|^2$$

(29)

Let $\tilde{P}$ be defined as in the proof of Lemma 2. Then we have

$$\|\bar{H}\|^2 = \|\tilde{P}^{1/2} + H \tilde{P}^{-1/2}\|^2 \leq 2 \left( \|\tilde{P}^{1/2}\|^2 + \|H \tilde{P}^{-1/2}\|^2 \right) \leq 2 \left( L_\beta^\max + \frac{\|H\|^2}{L_\beta^\min} \right)$$

(30)

Combining (28), (29) and (30), we have

$$F(x^{(t)}) - F(x^{(t+1)}) \geq \sum_{k=1}^P \frac{1}{2L_j^\beta} \|\nabla_j F(y^{(t,j)})\|^2 \geq \frac{\|\nabla F(x^{(t)})\|^2}{\|\bar{H}\|^2} \geq \frac{\|\nabla F(x^{(t)})\|^2}{2 \left( L_\beta^\max + \frac{\|H\|^2}{L_\beta^\min} \right)}.$$

D. Proof of Theorem 8

Successive Descent: For CBCGD, using the same analysis of Lemma 1, we have that for all $t \geq 1$,

$$F(x^{(t)}) - F(x^{(t+1)}) \geq \frac{L_\beta}{2} \|x^{(t)} - x^{(t+1)}\|^2.$$
For CBCM, using the same analysis of Theorem 4, we have that for all \( t \geq 1 \),
\[
\mathcal{F}(x(t)) - \mathcal{F}(x(t+1)) \geq \frac{\mu_{\min}}{2} \|x(t) - x(t+1)\|^2.
\]

**Gap towards the Optimal Objective Value:** By the strong convexity of \( R(\cdot) \), we have
\[
\mathcal{F}(x) - \mathcal{F}(x(t+1)) \geq \frac{\mu}{2} \|x - x(t+1)\|^2 + (x - x(t+1))^\top (\nabla L(x(t+1)) + \xi_t),
\]
where \( \xi_t \in \partial R_j(x^{(t+1)}) \). We then minimize both sides of (31) with respect to \( x \) and obtain
\[
\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \leq \frac{\|\nabla L(x(t+1)) + \xi_t\|^2}{2\mu}, \tag{32}
\]
For CBCGD, we have
\[
\|\nabla L(x^{(t+1)}) + \xi_t\|^2 (i) \leq \sum_{j=1}^p \|\nabla L(x^{(t+1)}) - \nabla_j L(y^{(t+1,j+1)}) - L_j(x^{(t+1)} - x_j^{(t)})\|^2
\]
\[
\leq \sum_{j=1}^p 2\|\nabla L(x^{(t+1)}) - \nabla_j L(y^{(t+1,j+1)})\|^2 + 2L_j^2 \|x_j^{(t+1)} - y_j^{(t+1,j)}\|^2
\]
\[
\leq 4pL^2 \|x^{(t+1)} - x^{(t)}\|^2, \tag{33}
\]
where (i) comes from the optimality condition
\[
\nabla_j L(y^{(t+1,j+1)}) + L_j(x_j^{(t+1)} - x_j^{(t)}) + \xi_j^{(t+1)} = 0.
\]
Combining (32) and (33), we have
\[
\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \leq \frac{2pL^2 \|x^{(t+1)} - x^{(t)}\|^2}{\mu}.
\]
For CBCM, we have
\[
\|\nabla L(x^{(t+1)}) + \xi_t\|^2 (i) \leq \sum_{j=1}^p \|\nabla L(x^{(t+1)}) - \nabla_j L(y^{(t+1,j+1)})\|^2
\]
\[
\leq pL^2 \|x^{(t+1)} - x^{(t)}\|^2, \tag{34}
\]
where (i) comes from the optimality condition
\[
\nabla_j L(y^{(t+1,j+1)}) + \xi_j^{(t+1)} = 0.
\]
Combining (32) and (34), we have
\[
\mathcal{F}(x^{(t+1)}) - \mathcal{F}(x^*) \leq \frac{pL^2 \|x^{(t+1)} - x^{(t)}\|^2}{2\mu}.
\]
**Iteration Complexity:** The analysis follows from that of Theorem 3.
