REduced Basis Approximations of the Solutions to Fractional Diffusion Problems

Andrea Bonito, Diane Guignard, and Ashley R. Zhang

Abstract. We consider the numerical approximation of the fractional diffusion problem based on the so-called Balakrishnan representation. The latter consists of an improper integral approximated via quadratures. At each quadrature point, a reaction-diffusion problem must be approximated and is the method bottleneck. In this work, we propose to reduce the computational cost using a reduced basis strategy allowing for a fast evaluation of the reaction-diffusion problems. The reduced basis does not depend on the fractional power \(s\) for \(0 < s_{\min} \leq s \leq s_{\max} < 1\). It is built offline once for all and used online irrespectively of the fractional power. We analyze the reduced basis strategy and show its exponential convergence. The analytical results are illustrated with insightful numerical experiments.

1. Introduction

Nonlocal models have recently received a great attention due to their apparent ability to capture novel effects such as in mechanics [22], peridynamics [16], turbulence [8], biophysics [7] and image denoising [14], to mention a few.

In most of the applications, the type of nonlocal interactions are different and their scaling laws are unknown. Initiated by the work [2], an algorithm is proposed and analyzed in [1] to identify the fractional power \(s \in [s_{\min}, s_{\max}]\) governing the state equation in an optimization framework. As expected, the algorithm exploits the smoothness of the map \(s \mapsto (-\Delta)^{-s}f\) and requires many (costly) evaluations of \((-\Delta)^{-s}f\) for different \(s \in (0, 1)\). Here for \(f \in L^2(\Omega)\), \(\Omega\) a Lipschitz domain of \(\mathbb{R}^d, d = 1, 2, 3\), we set

\[
(1) \quad u(s) := (-\Delta)^{-s}f := \sum_{k=1}^{\infty} \lambda_k^{-s} f_k \psi_k,
\]

where \(\{\lambda_k, \psi_k\}_{k \in \mathbb{N}} \subset \mathbb{R}^+ \times H^1_0(\Omega)\) are the eigenpairs of \((-\Delta)\) \((\psi_k\) are orthogonal in \(H^1_0(\Omega)\), orthonormal in \(L^2(\Omega)\)) and \(f_k := \int_{\Omega} f \psi_k\). In (1), the fractional operator is referred to as the spectral fractional Laplacian and is chosen in this work as prototype for nonlocal operators. The methodology proposed is however not limited to the fractional Laplacian and can be easily extended to regularly accretive operators as in [6].
Several numerical methods are available to approximate \((-\Delta)^{-s}f\), we refer to the surveys [3, 17] for the description of different fractional Laplacians along with their numerical approximations. In this work, we follow the approach in [5], see also [6], based on the Dunford-Taylor-Balakrishnan representation

\[
u(s) = \sin(s\pi) \int_{-\infty}^{\infty} e^{(1-s)y} w(y) dy,\]

where \(w(y) \in H^1_0(\Omega)\) solves

\[
(e^y I - \Delta)w(y) = f.
\]

Originally introduced in [5] and later improved in [4], a sinc quadrature coupled with a standard finite element method is used for the approximation of the integration in the variable \(y\). For \(k > 0\), it reads

\[
u(s) \approx k \sin(s\pi) \sum_{l=-M_s}^{N_s} e^{(1-s)y_l} w_h(y_l)
\]

with \(y_l := lk\),

\[
M_s := \left\lceil \frac{\pi}{2(1-s)k^2} \right\rceil, \quad N_s := \left\lceil \frac{\pi^2}{sk^2} \right\rceil
\]

and where \(w_h(y_l) \in \mathbb{V}_h\) are standard finite element approximations of \(w(y_l)\).

The numerical approximation of \((-\Delta)^{-s}f\) requires \(M_s + N_s + 1\) finite element solves to determine \(w_h(y_l), y_l \in [-M_s k, N_s k]\). This can become prohibitive when the computation of \((-\Delta)^{-s}f\) is needed for many values of \(s\) such as within an optimization loop as mentioned above. The reduced basis method seems to be a natural approach to reduce the computational cost when approximating the parametrized reaction-diffusion problems (2). In fact, reduced basis method for this type of one dimensional parametric elliptic partial differential equation has already been partially analyzed in [19, 18] and recently in [11] from which part of our analysis is inspired.

A (weak) greedy strategy is advocated (offline stage) to iteratively select snapshots \(w_h(y_l), l = 1, ..., n \ll \text{dim}(\mathbb{V}_h)\), defining the \(s\)-independent reduced basis space \(\mathbb{V}_h^n = \text{span}(w_h(y_l))\). Galerkin approximations \(u^n_h(y_l) \in \mathbb{V}_h^n\) of \(w_h(y_l)\) can then be easily computed (online stage) to produce a reduced basis approximation of \(u_{h,k}(s)\)

\[
u^n_{h,k}(s) = k \sin(s\pi) \sum_{l=-M_s}^{N_s} e^{(1-s)y_l} w^n_h(y_l).
\]

We point out that one of the difficulty faced in this study is that the approximation of the parametric elliptic partial differential equation (9) is required for \(y\) in the parametric domain \([-M_s k, N_s k]\) whose length increases as the sinc quadrature parameter \(k\) decreases (improving the precision of the algorithm).

The proposed algorithm provides an approximation of the entire map \(s \mapsto u(s), s \in [s_{\min}, s_{\max}]\) using the same reduced basis space \(\mathbb{V}_h^n\). Our main results is Theorem 4 and guarantees the exponential convergence of the reduced basis approximation \(u^n_{h,k}(s)\) toward \(u_{h,k}(s)\) in a wide range of Sobolev norms, uniformly in \(s\).

We end this introduction by noting that the idea of using the reduced basis method for fractional problems has been recently proposed in [11] and [13]. In [11]
the approximation of the map $s \mapsto (-\Delta)^s u$ is proposed for any $s \in [0, 1]$ and its exponential convergence in terms of the dimension of the reduced space is obtained. A reduced basis space based on a best rational approximations is constructed for the approximation of a reaction diffusion problem similar to the one satisfied by $u_h$. Worth mentioning, the numerical method is based on the extension method [20] but seemingly apply to other approximation technique. Actually, the method boils down to the approximation of several reaction diffusion problems as in [5]. In fact, we take advantage of the technology developed in [11] to derive an exponential decay in the approximation of (3) by (5). In [13], a similar approximation $u_{h,k}(s)$ is proposed for a different quadrature. Exponential decay of the reduced basis error is observed numerical but without analysis. In some sense, this work provides a mathematical justifications of the experimental observations in [13].

The rest of the paper is organized as follows. After describing the numerical approximation of $u(s)$ by $u_{h,k}(s)$ in Section 2, we discuss in Section 3 the construction of the reduced basis space along with its analysis. Numerical experiments are provided in Section 4 to illustrate the performance of the proposed methodology.

2. Spectral Fractional Laplacian and its Numerical Approximations

We start with some notations. Let $H^r(\Omega)$ be the interpolation space defined by

\begin{equation}
H^r(\Omega) := \left\{ \begin{array}{ll}
(L^2(\Omega), H^1_0(\Omega))_r & \text{for } r \in [0, 1] \\
H^1_0(\Omega) \cap H^r(\Omega) & \text{for } r \in (1, 2],
\end{array} \right.
\end{equation}

where $(\cdot, \cdot)_r$ denotes interpolation using the real method.

Notice that for the particular case $r = 1$, we have

$$
\|v\|_{H^1_0(\Omega)} := \|v\|_{H^1(\Omega)} = \|\nabla v\|_{L^2(\Omega)} \quad \forall v \in H^1_0(\Omega),
$$

which is equivalent to the $H^1(\Omega)$ norm thanks to the Poincaré inequality

\begin{equation}
\|v\|_{L^2(\Omega)} \leq C_P \|\nabla v\|_{L^2(\Omega)} \quad \forall v \in H^1_0(\Omega).
\end{equation}

To simplify the notation, we write when $r = 0$, $\|\cdot\| := \|\cdot\|_{L^2(\Omega)} = \|\cdot\|_{H^0}$.

Moreover, $a \lesssim b$ means that $a \leq Cb$ for a constant $C$ that does not depend on $a$, $b$ and the discretization parameters and whose value might change at each occurrence. Also, $a \approx b$ indicates $a \lesssim b$ and $b \lesssim a$.

2.1. Dunford-Taylor representation. The function $u(s) \in L^2(\Omega)$ in [1] has the following representation [24]

\begin{equation}
\frac{1}{2\pi i} \int_C \frac{z^s}{(z + \Delta)^{-1}} f dz,
\end{equation}

where $C$ is a Jordan curve oriented to have the spectrum of $-\Delta$ to its right. Deforming the contour $C$ to the negative real axis, we obtain the Balakrishnan formula, valid for $s \in (0, 1),

\begin{equation}
u(s) = \frac{\sin(s\pi)}{\pi} \int_0^\infty \mu^{-s}(\mu I - \Delta)^{-1} f d\mu.
\end{equation}

The numerical integration of the above improper integral relies on a sinc quadrature method after the change of variable $y = \ln(\mu)$, leading to

\begin{equation}
u(s) = \frac{\sin(s\pi)}{\pi} \int_{-\infty}^{\infty} e^{(1-s)y}(e^y I - \Delta)^{-1} f dy.
\end{equation}
2.2. **Finite element approximation.** We assume that $\Omega$ is a polyhedral domain and we consider a sequence \( \{T_h\}_{h>0} \) of conforming and shape-regular partitions of $\Omega$ into $d$-simplices with maximal mesh size $h < 1$. Let $V_h$ be the space of continuous and piecewise linear finite element functions associated to $T_h$. The finite element approximation of (10) reads
\[ u_h(s) := \frac{\sin(s\pi)}{\pi} \int_{-\infty}^{\infty} e^{(1-s)y} w_h(y) dy, \]
where $w_h(y) \in V_h$ is the solution of
\[ a(w_h(y), v_h; y) = F(v_h) \quad \forall v_h \in V_h. \]

Here we used the notation for $v \in H^1_0(\Omega)$ and
\[ F(v) := \int_{\Omega} f v, \]
for $v \in H^1_0(\Omega)$. The Poincaré inequality (7) imply that for $v, w \in H^1_0(\Omega)$,
\[ \|v\|^2_{H^1_0(\Omega)} \leq a(v, v; y) \quad \text{and} \quad a(v, w; y) \leq (1 + C_P e^y)\|v\|_{H^1_0(\Omega)} \|w\|_{H^1_0(\Omega)}, \]
which guarantees that (12) has a unique solution for any parameter $y \in \mathbb{R}$ thanks to the Lax-Milgram theory. We now collect estimates for $w_h(y)$ and note that (16)-left and (17) are favorable for negative $y$ while (16)-right, (18) and (19) for positive $y$. This will be used in the analysis below.

**Lemma 2.1.** Let $C_P$ be the Poincaré constant in (7). For any $y, \tilde{y} \in \mathbb{R}$ we have
\[ \|\nabla w_h(y)\| \leq C_P \|f\|, \quad \|w_h(y)\| \leq e^{\tilde{y}} \|f\|, \]
(16)
\[ \|\nabla (w_h(y) - w_h(\tilde{y}))\| \leq C_P^2 e^{y - \tilde{y}} \|f\|, \]
(17)
\[ \|w_h(y) - w_h(\tilde{y})\| \leq e^{\tilde{y}} |e^{y - \tilde{y}} - 1| \|f\|, \]
(18)
\[ \|\nabla (w_h(y) - w_h(\tilde{y}))\| \leq \frac{1}{2} e^{-\frac{y}{2}} |e^{y - \tilde{y}} - 1| \|f\|. \]
(19)

**Proof.** Choosing $v_h = w_h(y)$ in (12) yields
\[ \left\| \nabla w_h(y) \right\|^2 + e^{\tilde{y}} \|w_h(y)\|^2 = \int_{\Omega} f w_h(y) \leq \|f\| \|w_h(y)\| \]
from which the two relations in (16) can be easily deduced.

Using (12) again for $y$ and $\tilde{y}$, we write
\[ \int_{\Omega} \nabla (w_h(y) - w_h(\tilde{y})) \cdot \nabla v_h e^{y} \int_{\Omega} (w_h(y) - w_h(\tilde{y})) v_h = (e^{y} - e^{\tilde{y}}) \int_{\Omega} w_h(\tilde{y}) v_h \quad \forall v_h \in V_h. \]

We now chose $v_h = w_h(y) - w_h(\tilde{y})$ to get
\[ \|\nabla (w_h(y) - w_h(\tilde{y}))\|^2 + e^{\tilde{y}} \|w_h(y) - w_h(\tilde{y})\|^2 \leq |e^{y} - e^{\tilde{y}}| \|w_h(\tilde{y})\| \|w_h(y) - w_h(\tilde{y})\|. \]
(20)
This, the Poincaré inequality (7) and (16) with $y = \tilde{y}$ yield (17).
The estimate (18) follows from (20) together with (16) with \( y = \tilde{y} \). For (19), we invoke a Young inequality to estimate the right hand side of (20) and write

\[
\| \nabla (w_h(y) - w_h(\tilde{y})) \| \leq \frac{1}{2} e^{-\frac{\pi}{2}} |e^{\tilde{y}} - e^y| \| w_h(\tilde{y}) \|.
\]

It remains to invoke (16) with \( y = \tilde{y} \) to derive the desired result and ends the proof.

We end this section by stating the error in the finite element method derived and analyzed in [6]. Before doing this, we define \( \alpha \in (0, 1] \) to be the elliptic pick-up regularity index, i.e. \( \alpha \) is the largest number in \( (0, 1] \) such that \( (-\Delta) \) is an isomorphism from \( H^r(\Omega) \) to \( H^{r+1}(\Omega) \) for all \( r \in [0, \alpha] \). Notice that \( \alpha > 0 \) for Lipschitz domains and \( \alpha = 1 \) when \( \Omega \) is convex.

**Theorem 1.** Let \( f \in L^2(\Omega) \), \( \alpha > 0 \) denote the elliptic regularity pick-up and \( \alpha^* := \frac{\alpha + \min\{\alpha, 1 - r\}}{2} \). Then for any \( r \in [0, 1] \), we have

1. If \( r + 2\alpha^* - 2s \geq 0 \) and \( f \in H^{r+2\alpha^*-2s}(\Omega) \) then

\[
\|u - u_h\|_{H^r(\Omega)} \lesssim \ln(h^{-1}) h^{2\alpha^*} \|f\|_{H^{r+2\alpha^*-2s}(\Omega)}.
\]

2. If \( r + 2\alpha^* - 2s \geq 0 \) and \( f \in H^{r+2\alpha^*-2s+2\varepsilon}(\Omega) \) with \( r + 2\alpha^* - 2s + 2\varepsilon \leq 1 + \alpha \) then

\[
\|u - u_h\|_{H^r(\Omega)} \lesssim h^{2\alpha^*} \|f\|_{H^{r+2\alpha^*-2s+2\varepsilon}(\Omega)}.
\]

3. If \( r + 2\alpha^* - 2s < 0 \) then

\[
\|u - u_h\|_{H^r(\Omega)} \lesssim h^{2\alpha^*} \|f\|_{L^2(\Omega)}.
\]

**2.3. Sinc quadrature approximation.** We next discuss the sinc quadrature approximation leading to the fully discrete approximation \( u_{h,k} \) given by (3). Recall that \( k > 0 \) is the sinc quadrature parameter and that \( M_s, N_s \) are given by (4). This choice is dictated from the analysis of the sinc quadrature error, which is the subject of the following theorem; we refer to [4] for its proof.

**Theorem 2.** Let \( f \in L^2(\Omega) \) and \( r \in [0, 1] \).

1. If \( s > r/2 \) then

\[
\|u_h(s) - u_{h,k}(s)\|_{H^r(\Omega)} \lesssim \left( e^{-\frac{2s}{r}} + e^{-(1-s)M_s k} + e^{-sN_s k} \right) \| f \|_{L^2(\Omega)}.
\]

2. If \( s \leq r/2 \) and \( f \in H^{r-2s+\varepsilon}(\Omega) \) with \( r - 2s + \varepsilon \in [0, 1 + \alpha] \) then

\[
\|u_h(s) - u_{h,k}(s)\|_{H^r(\Omega)} \lesssim \left( e^{-\frac{2s}{r}} + e^{-(1-s)M_s k} + e^{-sN_s k} \right) \| f \|_{H^{r-2s+\varepsilon}(\Omega)}.
\]

**3. Reduced Basis Approximation**

The computation of \( u_{h,k} \) in (3) involves the finite element solution \( w_h(y) \) to the reaction diffusion problem (12) for \( M_s + N_s + 1 \) different values of the parameter \( y \in \mathcal{D}_s := [-M_s k, N_s k] \). We propose to use the reduced basis technology to approximate the entire map \( y \mapsto w_h(y) \). Notice that the bilinear form \( a(\cdot, \cdot; y) \) defining \( w_h(y) \) in (12) is not affine in \( y \). However, it becomes affine for \( \mu := c^2 \).
3.1. Construction for a fix \( s \). The reduced basis space
\[ V_h^m := \text{span}(w_h(y^1), ..., w_h(y^m)) \subset V_h \]
is constructed using a greedy strategy. Starting with \( y^1 = 0 \), \( y^{m+1} \in D_s \) is selected iteratively as to maximize the error
\[ (21) \quad W_m(y) := \|w_h(y) - P_{V_h^m} w_h(y)\|_{H^1_0(\Omega)} \]
on \( D_s \), i.e.
\[ y^{m+1} := \arg\max_{y \in D_s} W_m(y). \]
Here \( P_{V_h^m} w_h(y) \in V_h^m \) is the unique solution (from Lax-Milgram theory) to
\[ (22) \quad a(P_{V_h^m} w_h(y), v) = a(w_h(y), v) \quad \forall v \in V_h^m. \]
Notice that in view of the definition \([12]\) of \( w_h(y) \), the above relation is equivalent to
\[ a(P_{V_h^m} w_h(y), v_m; y) = F(v_m) \quad \forall v_m \in V_h^m. \]
The enrichment of the reduced basis space ends when
\[ (23) \quad \max_{y \in D_s} W_m(y) \leq \varepsilon \|f\| \]
for a prescribed accuracy \( \varepsilon > 0 \) or when a maximum number of basis functions \( N_{\text{max}} \) is reached.

The error \( W_m(y) \) defined in \((21)\) is not a computable quantity and is usually replaced by an equivalent computable quantity leading to the so-called weak greedy algorithm. In this work, we use the residual based \textit{a posteriori} error estimate
\[ (24) \quad \|r_m(; y)\|_{H^{-1}(\Omega)} := \sup_{v \in H^1_0(\Omega)} \frac{r_m(v; y)}{\|v\|_{H^1_0(\Omega)}}, \]
where
\[ r_m(v; y) := F(v) - a(P_{V_h^m} w_h(y), v; y) \]
and \( H^{-1}(\Omega) \) is the dual space of \( H^1_0(\Omega) \). The coercivity and continuity \([15]\) yield the following equivalence relation between the error \( W_m(y) \) and its surrogate
\[ (25) \quad (1 + C_p e^y)^{-1} \|r_m(; y)\|_{H^{-1}(\Omega)} \leq W_m(y) \leq \|r_m(; y)\|_{H^{-1}(\Omega)} \]
for all \( y \in \mathbb{R} \). Hence, selecting the samples using \( \|r_m(; y)\|_{H^{-1}(\Omega)} \) as surrogate for the error \( W_m(y) \) yields
\[ W_m(y^{m+1}) \geq \gamma_s \max_{y \in D_s} W_m(y) \]
with
\[ (26) \quad \gamma_s := \left( \max_{y \in D_s} (1 + C_p e^y) \right)^{-1} = (1 + C_p e^{N_s k})^{-1}. \]
The parameter \( \gamma_s \) corresponds to the constant in the weak greedy algorithm and will appear in our estimate below.

The dual norm can be computed using the Riesz representation theorem, see for instance \([21]\) for more details. However, evaluating \( \|r_m(; y)\|_{H^{-1}(\Omega)} \) for every \( y \) in \( D_s \) remains unfeasible. In practice, the maximization is performed over a finite dimensional \textit{training set} \( \Theta_s \subset D_s \), either chosen sufficiently fine to retain the performance of the algorithm, see for instance \([10]\), or based on a random selection of moderate size as recently introduced and analyzed in \([9]\).
The reduced basis space is constructed offline and give the following online approximation of \( u_{h,k}(s) \)

\[
\begin{align*}
  u_{h,k}^n(s) := \frac{k \sin(s\pi)}{\pi} \sum_{l=-M_s}^{N_s} e^{(1-s)\pi} u_h^n(y_l), \quad w_h^n(y_l) := P_{V_n} w_h(y_l).
\end{align*}
\]

3.2. Error analysis for a fix \( s \). We now analyze the distortion between \( u(s) = (-\Delta)^{-s} f \) and its reduced basis approximation \( u_{h,k}^n(s) \) given by (27) in the \( \mathbb{H}^r(\Omega) \) norm. In order to avoid unnecessary technicalities, we assume from now on that \( r \in [0,1] \) is chosen such that \( r < 2s \), which include the natural choice \( r = s \) leading to the energy error and \( r = 0 \) for the \( L^2(\Omega) \) error. The discussion below can be readily extended to the case \( r \geq 2s \) by accounting for the begin log factor in the finite element approximation (see Theorem 1).

For \( u(s) \in \mathbb{H}^r(\Omega) \), we decompose the error into three parts

\[
\begin{align*}
  \|u(s) - u_{h,k}^n(s)\|_{\mathbb{H}^r(\Omega)} &\leq \|u(s) - u_h(s)\|_{\mathbb{H}^r(\Omega)} + \|u_h(s) - u_{h,k}(s)\|_{\mathbb{H}^r(\Omega)} \\
&\quad + \|u_{h,k}(s) - u_{h,k}^n(s)\|_{\mathbb{H}^r(\Omega)}
\end{align*}
\]

corresponding to the finite element error, the sinc quadrature error and the reduced basis error, respectively. Given a target tolerance \( \varepsilon > 0 \), we construct the reduced basis space such that (23) holds. In view of Theorems 1 and 2, we select the space discretization and sinc quadrature parameters \( h \) and \( k \) to balance the finite element and sinc quadrature errors, i.e.

\[
C_{\text{FEM}} h^{2s^*} = C_{\text{SINC}} e^{-\frac{\pi^2}{h^2}} = \varepsilon
\]

for some absolute constants \( C_{\text{FEM}} \) and \( C_{\text{SINC}} \).

We now assess the error in the reduced basis modeling by analyzing the behavior of \( \|u_{h,k}(s) - u_{h,k}^n(s)\|_{\mathbb{H}^r(\Omega)} \) as \( n \) increases. From the definitions (3) and (27) of \( u_{h,k}(s) \) and \( u_{h,k}^n(s) \), respectively, we have

\[
\begin{align*}
  \|u_{h,k}(s) - u_{h,k}^n(s)\|_{\mathbb{H}^r(\Omega)} &\leq \frac{k \sin(s\pi)}{\pi} \sum_{l=-M_s}^{N_s} e^{(1-s)\pi} \|w_h(y_l) - w_h^n(y_l)\|_{\mathbb{H}^r(\Omega)}.
\end{align*}
\]

Key ingredients in our analysis are estimates for reduced basis errors \( \|w_h(y_l) - w_h^n(y_l)\|_{\mathbb{H}^r(\Omega)} \) in approximating the inner problems. We discuss this now and bound

\[
\begin{align*}
  \sup_{y \in D_s} \|\nabla(w_h(y) - w_h^n(y))\| = \sup_{y \in D_s} \|\nabla(w_h(y) - P_{V_n} w_h(y))\|.
\end{align*}
\]

The Kolmogorov \( n \)-width

\[
\begin{align*}
  d_n := \inf_{\dim(Y_n) \leq n} \sup_{y \in D_s} \inf_{v_n \in Y_n} \|\nabla(w_h(y) - v_n)\|, \quad n \geq 1,
\end{align*}
\]

is the benchmark for the best achievable decay. By convention, we set

\[
\begin{align*}
  d_0 := \sup_{y \in D_s} \|\nabla w_h(y)\|.
\end{align*}
\]

It is quite remarkable that the linear space \( V_n \) constructed by the (weak) greedy selection discussed in Section 3.1 leads to an error (31) equivalent to \( d_n \). In particular an exponential decay of the Kolmogorov \( n \)-width guarantees an exponential decay of the (weak) greedy error. In order to prove that the error in (31) decays exponentially with \( n \), see Lemma 3.1 below, we will thus show that the Kolmogorov \( n \)-width exhibits an exponential decay.
To facilitate the analysis of $d_n$, we use the notations in \cite{13} and provide a representation of the finite element functions $w_h(y)$ in term of the eigenpairs $\{\mu_i, \varphi_i\}_{i=1}^{N_h} \subset \mathbb{R}^+ \times \mathcal{V}_h$, $N_h := \dim(\mathcal{V}_h)$, of the generalized eigenvalue problem
\[
a_1(\varphi_i, v_h) = \mu_i a_0(\varphi_i, v_h), \quad \forall v_h \in \mathcal{V}_h.
\]
Without loss of generality, we assume that the $\varphi_i$ are $H^1_0$-orthonormal, i.e.
\[
a_0(\varphi_i, \varphi_j) = \delta_{ij}, \quad 1 \leq i, j \leq N_h.
\]
Thanks to the Poincaré inequality \cite{17} and the inverse inequality
\[
\|\nabla v_h\| \leq C_i h^{-1} \|v_h\|, \quad \forall v_h \in \mathcal{V}_h,
\]
we find that
\[
C_i^{-2} h^2 \leq \mu_i \leq C_P^2, \quad 1 \leq i \leq N_h.
\]
With these notations, we can rewrite $w_h(y)$ in \cite{12} as
\[
w_h(y) = \sum_{i=1}^{N_h} \frac{f_i \varphi_i}{1 + e^{y \mu_i}}, \quad f_i := F(\varphi_i).
\]

We are now in position to assess the reduced basis approximation property.

**Lemma 3.1.** For any $n \geq 1$ we have
\[
\sup_{y \in D_s} \|\nabla (w_h(y) - P_n w_h(y))\| \leq \gamma_s^{-1} C_1 e^{-C_2(h)n} \|f\|,
\]
where $\gamma_s$ is given by \cite{26}, $C_1$ is a constant only depending on $C_P$ and
\[
C_2(h) \approx \frac{1}{\ln(C_P^2 C_i^2 h^{-2})} \quad \text{when } h \to 0.
\]

**Proof.** We follow \cite{11} to construct a linear space $\mathcal{W}_n \subset \mathcal{V}_h$ with $\dim(\mathcal{W}_n) \leq n$ such that for some constants $c_1, c_2$ and $n \geq 1$ we have
\[
d_n \leq \sup_{y \in D_s} \inf_{v_h \in \mathcal{W}_n} \|\nabla (w_h(y) - v_h)\| \leq c_1 e^{-c_2n} \|f\|.
\]
Let $\mathcal{W}_h := \text{span}\{w_h(y_j) : j = 1, \ldots, n\}$ where the $y_j$ are chosen such that the $e^{y_j}$ are the transformed Zolotarëv points $[C_P^2, C_i^2 h^{-2}]$ as in \cite{11}, see also \cite{15, 29}. Notice that this interval is dictated by the lower and upper bound of the eigenvalues $\mu_i$, see \cite{14}. Now, given $y \in D_s$, we define the approximation
\[
v_h^n(y) := \sum_{j=1}^{n} \alpha_j(y) w_h(y_j) \in \mathcal{W}_h,
\]
where the coefficients $\alpha_j(y)$ are such that
\[
\frac{1}{1 + e^{y \mu_i}} = \sum_{j=1}^{n} \alpha_j(y) \frac{1}{1 + e^{y_j \mu_i}}, \quad k = 1, \ldots, n.
\]
The above system is a particular rational interpolation problem and has a unique solution according to Lemma 5.13 in \cite{11}. Furthermore, thanks to Lemma 5.17 in \cite{11}, we have
\[
\left| \frac{1}{1 + e^{y \mu_i}} - \sum_{j=1}^{n} \alpha_j(y) \frac{1}{1 + e^{y_j \mu_i}} \right| \leq \frac{1}{1 + e^{y \mu_i}} e^{-C^* n}, \quad i = 1, \ldots, N_h,
\]
where
\[ C^* = C^*(h) \approx \frac{1}{\ln(C_P^* C_2^* h^{-2})}. \]

Hence, the error between \( w_h(y) \) in (35) and \( v_h^n(y) \) in (39) satisfies
\[
\| w_h(y) - v_h^n(y) \|_{H^1_0}^2 = \sum_{i=1}^{N_h} f_i^2 \left( \frac{1}{1 + e^{y_i \mu_i}} - \sum_{j=1}^{n} \alpha_j(y) \frac{1}{1 + e^{y_j \mu_i}} \right)^2 \lesssim e^{-2C^* n} \sum_{i=1}^{N_h} f_i^2 \left( \frac{1}{1 + e^{y_i \mu_i}} \right)^2 \lesssim e^{-2C^* n} \| \nabla w_h(y) \|^2,
\]

where we have used the \( H^1_0 \)-orthonormality of the \( \{ \varphi_i \}_{i=1}^{N_h} \). With the help of (16), this implies
\[
\| w_h(y) - v_h^n(y) \|_{H^1_0}^2 \lesssim e^{-2C^* n} C^*_P \| f \|^2.
\]

The above estimate is (38) with \( c_2 = C^* \) and where \( c_1 \) only depends on \( C_P \) and the hidden constant in (40). Moreover, thanks to (16) we also have \( d_0 \leq C_P \| f \| \), where \( d_0 \) is defined in (33). Therefore, we have shown that the Kolmogorov \( n \)-width (see (32) and (33)) satisfies
\[
d_n \leq c_1 e^{-c_2 n} \| f \|, \quad n \geq 0.
\]

To conclude, it remains to relate the error decay of the reduced basis generated by the weak greedy algorithm with parameter \( \gamma_s \) (see (26)) and the Kolmogorov \( n \)-width \( d_n \). Corollary 8.4 in [10], see also Corollary 3.3 in [12], guarantees that (41) implies (36) with \( C_2 = c_2/6 = C^*/6 \) and \( C_1 = c_1 \max(\sqrt{2}, \gamma_s e^{C_2}) \lesssim c_1 \). \( \square \)

**Remark 1.** We mention that an exponential decay for the reduced basis error for one dimensional parametric problem of the form (12) has already been obtained in [13] [18]. However, the exponential decay is guaranteed for \( n \geq n_{\text{crit}} \) for some integer \( n_{\text{crit}} \) depending on the length of the parameter interval \([-M_s k, N_s k]\). We did not pursue this route as the latter restriction seems prohibitive to take full advantage of the performances of the reduced basis method.

We now use the exponential decay of the reduced basis error for \( w_h \) obtained in Lemma 3.1 to estimate the error for \( u_{h,k} \) defined in (30).

**Lemma 3.2.** Let \( h \) and \( k \) be the finite element and sinc quadrature parameters. Let \( r \in [0, 1] \). For \( n \geq 1 \), we have
\[
\| u_{h,k}(s) - u_{h,k}^n(s) \|_{H^r(\Omega)} \leq \frac{\sin(s\pi)}{(1-s)^{1-r}} C_1 e^{-C_2(h)n} \left( e^{(1-s)N_s k} - e^{-(1-s)M_s k} \right) \| f \|,
\]

where \( C_1 \) and \( C_2(h) \) are the constants in (36).

**Proof.** Because \( H^r(\Omega) \) are interpolation spaces between \( L^2(\Omega) \) and \( H^1_0(\Omega) \), see (6), the Poincaré inequality (7) yields
\[
\| w_h(y) - w_h^n(y) \|_{H^r(\Omega)} \leq \| w_h(y) - w_h^n(y) \|^{1-\tau} \| \nabla (w_h(y) - w_h^n(y)) \|^{\tau} \leq C_P^{1-r} \| \nabla (w_h(y) - w_h^n(y)) \|.
\]
Therefore, using the estimate \( (30) \) for the error and invoking Lemma 3.1, we get
\[
\| u_{h,k}(s) - u_{h,k}^n(s) \|_{H^r(\Omega)} \leq k \sin(s\pi) \frac{C_1}{\pi} \left( C_2e^{-C_2(h)n} \sum_{l=-M,N} e^{(1-s)y_l} \right) \| f \|_{N_{k}^{s}} \leq \sin(s\pi) \frac{C_1}{\pi} \left( C_2e^{-C_2(h)n} \right) \| f \|_{N_{k}^{s}} - \frac{1}{(1-s)\pi} C_1 \frac{C_2}{\pi} e^{-C_2(h)n} \| f \|_{N_{k}^{s}} - \frac{1}{(1-s)\pi} C_1 \frac{C_2}{\pi} e^{-C_2(h)n} \| f \|_{N_{k}^{s}} \leq \sin(s\pi) \frac{C_1}{\pi} \left( C_2e^{-C_2(h)n} \right) \| f \|_{N_{k}^{s}} - \frac{1}{(1-s)\pi} C_1 \frac{C_2}{\pi} e^{-C_2(h)n} \| f \|_{N_{k}^{s}} \leq \sin(s\pi) \frac{C_1}{\pi} \left( C_2e^{-C_2(h)n} \right) \| f \|_{N_{k}^{s}} - \frac{1}{(1-s)\pi} C_1 \frac{C_2}{\pi} e^{-C_2(h)n} \| f \|_{N_{k}^{s}}
\]
which is the claimed estimate.

\[\square\]

**Remark 2.** From \( (37) \), we see that the constant \( C_2(h) \) that appears in \( (36) \) and \( (42) \) tends to 0 as \( h \) tends to 0. In other words, the reduced basis performances deteriorate as the target accuracy \( \varepsilon \) tends to 0. This phenomenon is observed in the numerical experiments reported in Figure 4 of Section 4.

Using Lemma 3.2, we directly derive the following result providing a sufficient condition on the dimension \( n \) of the reduced space to achieve an error under a specified tolerance \( \delta > 0 \).

**Theorem 3.** (offline construction of the reduced space) Let \( \varepsilon > 0 \) be a given tolerance. Assume that \( h \) and \( k \) are chosen so that \( (29) \) holds and that the reduced basis space is constructed such that \( (23) \) holds. Then, for any \( \delta \geq \varepsilon \) we have
\[
\| u_{h,k}(s) - u_{h,k}^n(s) \|_{H^r(\Omega)} \leq \delta \| f \| _{N_{k}^{s}}
\]
provided
\[
n \approx \ln(C\delta \varepsilon \frac{2-s}{\pi}) \ln(\varepsilon^{1/\alpha^*})
\]
where \( C \) is a constant only depending on \( s \) and \( r \) and \( \alpha^* \) is as in Theorem 1. In particular
\[
n \approx \ln(\varepsilon)^2
\]
when \( \delta = \varepsilon \).

**Proof.** The claims directly follow from Lemma 3.2 together with \( (29) \). \[\square\]

### 3.3. Universal reduced basis space.

In the previous section we constructed a reduced basis space \( V_n^\gamma \) to approximate \( u_{h,k}(s) \) for a fixed \( s \in (0,1) \). We now show that it is possible to take real advantage of the offline work and construct reduced basis spaces approximating the map \( s \mapsto u_{h,k}(s) \) for \( s \in [s_{\text{min}}, s_{\text{max}}] \), with \( 0 < s_{\text{min}} \leq s_{\text{max}} < 1 \) fixed.

To see this, it suffices to adjust the constant depending on \( s \) as follows. First, we let
\[
M := \left( \frac{\pi^2}{(1-s_{\text{max}})k^2} \right) \quad \text{and} \quad N := \left( \frac{\pi^2}{s_{\text{min}}k^2} \right).
\]

Then, we define the domain \( D := [-Mk, Nk] \) containing \( D_s \) for all \( s \in [s_{\text{min}}, s_{\text{max}}] \) and, similarly to \( (26) \), we introduce the parameter
\[
\gamma := \left( \max_{y \in D} (1+Ce^y) \right)^{-1} = (1+Ce^{Nk})^{-1}.
\]
Finally, for all \( y \in \mathcal{D} \) we approximate \( w_h(y) \) by \( w^n_h(y) = P^n_h w_h(y) \), where the reduced basis space \( \mathcal{V}^n_h \) is constructed as detailed in Section 3.1 upon replacing \( M_s, N_s, D_s \) and \( \gamma_s \) by \( M, N, D \) and \( \gamma \), respectively.

With this uniform construction, we directly obtain the universal version of Lemma 3.2 and Theorem 3.

**Lemma 3.3.** Let \( h \) and \( k \) be the finite element and sinc quadrature parameters. Let \( r \in [0, 1] \). For \( n \geq 1 \) and any \( s \in [s_{\text{min}}, s_{\text{max}}] \) we have

\[
\|u_{h,k}(s) - u^n_{h,k}(s)\|_{H^r(\Omega)} \leq \frac{\sin(s\pi)}{(1-s)\pi} C_{1}^{1-r} C_{2}^{-1} e^{-C_{2} h} \left( e^{(1-s)Nk} - e^{-(1-s)Mk} \right) \|f\|,
\]

where \( C_1 \) and \( C_2 \) are the constants in (36).

**Theorem 4.** (offline construction of the universal reduced space) Let \( \varepsilon > 0 \) be a given tolerance. Assume that \( h \) and \( k \) are chosen so that (23) holds and that the reduced basis space is constructed such that (23) holds. Then, for any \( \delta \geq \varepsilon \) we have

\[
\max_{s \in [s_{\text{min}}, s_{\text{max}}]} \|u_{h,k}(s) - u^n_{h,k}(s)\|_{H^r(\Omega)} \leq \delta \|f\|
\]

provided

\[
n \approx \ln(C\delta e^{2^{-s_{\text{min}}}}) \ln(e^{1/\alpha^*}),
\]

where \( C \) is a constant only depending on \( s_{\text{min}}, s_{\text{max}} \) and \( r \), and \( \alpha^* \) is as in Theorem 3. In particular

\[
n \approx \ln(\varepsilon)^2
\]

when \( \delta = \varepsilon \).

4. Numerical Experiments

We present numerical results to illustrate the performances of the reduced basis approach analyzed in the previous section. Since the focus of this paper is on the reduced basis approximation, unless otherwise specified the finite element meshsize \( h \) and the sinc quadrature parameter \( k \) are chosen sufficiently small not to influence the overall error. Recall that the space \( \mathcal{V}^n_h \) is built using the weak greedy algorithm on \([-Mk,Nk]\) starting with the snapshot \( w_h(0) \). The training set \( \Theta \) consists of 10000 uniformly distributed points in \([-Mk,Nk]\). In all numerical examples, we set \( f = 1 \).

4.1. 1D example. We consider the case \( \Omega = (0,1) \). The subdivision \( \mathcal{T}_h \) of \( \Omega \) consists of a uniform partition of \([0,1]\) with subintervals of length \( h = 2^{-12} \). The sinc quadrature parameter is fixed to \( k = 0.5 \) and the fractional power \( s \) varies from \( s_{\text{min}} = 0.1 \) to \( s_{\text{max}} = 0.9 \). In this setting, we have \( N = M = 395 \) and \([-Mk,Nk] = [-197.5,197.5] \).

4.1.1. Reduced basis error for \( w_h \). We provide in Figure 1-left the evolution of

\[
e_w(n) := \sup_{y \in \Theta} \|w_h(y) - P^n_h w_h(y)\|_{H^r(\Omega)}
\]

versus \( n \geq 1 \) as indicator of the error

\[
\sup_{y \in [-Mk,Nk]} \|w_h(y) - P^n_h w_h(y)\|_{H^r(\Omega)}.
\]

The observed exponential decay matches the estimate of Lemma 3.1.
Moreover, Figure 1-right reports the values of the selected parameters $y^n$ by the weak greedy procedure. We observe that except for $y^2$ they are all located in the interval $[0, 20]$. This behavior can be in part explained by the estimates provided in Lemma 2.1 indicating the robustness of $w_h(y)$ for small values of $y$ and the smallness of $\|w_h(y)\|$ for $y$ large.

![Figure 1](image1.png)

**Figure 1.** Left: reduced basis error $e_w(n)$ versus $n$. Right: parameters $y^n$ selected by the weak greedy procedure during the construction of the reduced basis space.

We comment on the use of an a posteriori error estimate (weak greedy) in place of the true error (greedy), see (25). For this, we compare in Figure 2 the performance of both algorithms and conclude that very little efficiency is lost in using the computable a posteriori error estimator.

![Figure 2](image2.png)

**Figure 2.** Comparison of the greedy and weak greedy strategies. Right: error $e_w(n)$ associated with the greedy and weak greedy strategies. The dashed line represents the equivalent quantity $\max_{y \in \Theta} \|r_n(\cdot, y)\|_{H^{-1}(\Omega)}$, see (25). Left: selected parameters $y$ for both strategies.

4.1.2. Reduced basis error for $u_{h,k}$. We now turn our attention to the approximation of $u_{h,k}(s)$ by $u_{h,k}^n(s)$. Figure 3 depicts the evolution of

$$e_u(s)(n) := \|u_{h,k}(s) - u_{h,k}^n(s)\|$$

for various values of fractional power. In agreement with Theorem 4, exponential decay is observed in all cases when using the universal reduced basis space. Notice
that in this experiment the sinc quadrature requires 440 points for $s = 0.1, 0.9, 190$ points for $s = 0.3, 0.7$ and 159 points for $s = 0.5$ to guarantee a sinc quadrature error of the order $e^{-\pi^2/k} \approx 2.7 \times 10^{-9}$ for $k = 0.5$. A comparable reduced basis accuracy in the $L^2(\Omega)$ norm is achieved for only $n = 20$ for $0.5 \leq s \leq 0.9$.

Finally, we study numerically the behavior of the constant $C_2(h)$ given by (37). We set $s = 0.1$ and consider a sequence of uniform partitions of $[0, 1]$ with subintervals of length $h = 2^{-k}$ for $k = 6, 8, 10, 12$. The reduced basis error $e_{u(0.1)}(n)$ versus $n$ is reported in Figure 4 for each finite element discretization. As predicted by Theorem 4, the exponential decay encoded in $C_2 = C_2(h)$ deteriorate when $h \to 0$. The $L^2(\Omega)$ norm of the error behaves like $e^{-1.4n}$ for $h = 2^{-6}$ and $e^{-0.7n}$ for $h = 2^{-12}$.

4.2. 2D examples. We now consider two dimensional domains: a square domain $\Omega = (0, 1)^2$ and a L-shaped domain $\Omega = (0, 1)^2 \setminus ([0, 0.5] \times [0.5, 1])$. The space discretization consists of a Delaunay triangulation with 22968 for $\Omega = (0, 1)^2$ and 17190 elements for $\Omega = (0, 1)^2 \setminus ([0, 0.5] \times [0.5, 1])$. In both cases, the elements in
the triangulation have diameters between 0.005 and 0.01. All the other parameters are as in Section 4.1.

The evolution of the reduced basis error $e_{u(s)}(n)$ for different values of $s$ is reported in Figure 5. As for the one dimensional case, exponential decays are observed for all values of $s \in [0.1, 0.9]$ and irrespectively of the shape of the domain.

Figure 5. Error $e_{u(s)}(n)$ with respect to $n$ for various values of $s$ in $[0.1, 0.9]$. Left: unit square domain. Right: $L$-shape domain.
