Abstract

Background and Objective: The WHO has stressed to regularly monitor the mental health of populations during the COVID-19 pandemic. As a result, we conducted this study to examine anxiety and depression among recovered and recovering COVID-19 patients.

Methods: An online survey was conducted using a social media platform from 31/05/2020 to 24/06/2020. The study participants were COVID-19 infected individuals who had recovered or still were in the recovery phase from COVID-19. We collected information on demographics, clinical characteristics and physical complications of COVID-19. Anxiety and depressive symptoms were assessed using previously validated tools. Descriptive statistics and logistic regression were applied to analyze the data.

Results: 53.4% of respondents reported that they had a fear of getting COVID-19 again. Anxiety and depressive symptoms were present in 71.7% and 97.6% of respondents respectively. Both disorders were present in 71.3% of respondents. The respondents with shorter durations of physical symptoms (< 2 weeks) demonstrated less anxiety (OR = 0.19; 95% CI: 0.05 - 0.67) and depression (OR = 0.03; 95% CI: 0.01 - 0.37).

Conclusion: Anxiety and depression appear as common psychological complications in COVID-19 recovering and recovered patients. Longer durations of COVID-19 related physical symptoms were associated with an increased likelihood of anxiety and depression.

Key Points

- Depression and severe anxiety were present in the majority of COVID-19 patients.
- 98% of COVID-19 infected respondents had at least one psychological disorder.
- 71.3% of COVID-19 infected respondents had both depression and anxiety disorder.
- Longer infection durations of the physical symptoms of COVID-19 significantly increases the likelihood of the incidence of depression and anxiety.

Introduction

Since the beginning of the 21st century, humanity has encountered and contained two major viral outbreaks of Coronavirus, namely Severe Acute Respiratory Syndrome (SARS) emerging in 2002 and Middle East Respiratory Syndrome (MERS) in 2012 (Desforges et al., 2020). COVID-19 is a novel infectious disease of the same Coronavirus family caused by a virus called SARS-COV-2 (WHO, 2020). Starting in December 2019, COVID-19 spread very rapidly over the globe and was declared a pandemic by the World Health Organization (WHO) (WHO, 2020). As of 12:01 PM, 8th of August 2020, the total number of COVID-19 infections had surpassed a figure of 19 million cases, resulting in more than seven hundred thousand deaths globally. These infections are still increasing (WHO, 2020). A substantial number of COVID-19 patients are recovering and being discharged from hospital (WHO, 2020). Despite
recovering from the infection, the patients experience a wide range of physical and mental health complications (Rajkumar, 2020). Other than the delirium experienced during the quarantine and recovery phases, the incidence of various psychological disorders especially anxiety have been documented in previous studies (Holmes et al., 2020; Rogers et al., 2020; Brooks et al., 2020). Several studies have analyzed the psychological issues of patients recovering from exposure to previous infectious diseases including SARS, MERS and EBOLA and observed various psychological complications (Lee et al., 2007; Hawryluck et al., 2004; Kim et al., 2018; Yadav and Rawal, 2015). A systematic review and meta-analysis on SARS, MERS and COVID-19 patients in recovery reported a lower likelihood of serious mental illness overall. However, the same study indicated the possibility of anxiety and depressive symptoms among the COVID-19 individuals (Rogers et al., 2020). Further research compared the psychological condition of MERS patients during their quarantined period supported by 4-6 months follow up data. The findings reported reduction in anxiety prevalence from 7% to 3% (Jeong et al., 2016). Concerning COVID-19, a recent article reported that anxiety and depressive symptoms were present in 34.72% and 28.47% of the patients respectively (Kong et al., 2020). A further study revealed that the scores for both disorders were significantly higher among COVID-19 patients than a healthy control group (Yang et al., 2020). The available data regarding psychological complications among COVID-19 recovered patients are not substantial, and yet the need for early intervention has been emphasized by earlier research studies (Galea et al., 2020; Xiang et al., 2020). The purpose of this study therefore was to investigate psychological disorders among COVID-19 patients that have recovered and patients that are still in the recovery phase.

**Methods**

An online survey was conducted using Google platform. The link to the survey was made available to various COVID-19 recovered patients with access to social media. The patients were asked to participate in the survey and encouraged to send the survey link to further COVID-19 patient populations in recovery. Data collection commenced on 31/05/2020 at 4.30 pm (IST) and terminated on 24/06/2020. All the relevant information regarding the purpose of the study, procedures, anonymity and ethical approval details were provided on the front page of the Google form. A statement of informed consent to participate in the study was included on the survey form. Only individuals who provided their written informed consent to participate were included in the study.

**Survey tools**

The survey tools comprised of two parts. The first part included demographic information such as name (optional), age, gender, country, occupation and blood group. Further, we collected information regarding the clinical characteristics of subjects such as information regarding the COVID-19 test report. This included information about whether the patients were hospitalized or not, time spent thinking about COVID-19, recovery time, medical consultation, fear of getting COVID-19 again, physical complications during the recovery phase and physical complications after recovery from COVID-19. The second part included the use of validated questionnaires. These included the Center for Epidemiological Studies
Depression Scale (CES-D) to examine depressive symptoms (Radloff, 1977) and the Generalized Anxiety Disorder (GAD-7) scale to assess the anxiety levels of the patients (Spitzer et al., 2006).

Data Analyses

Descriptive statistics of demographic variables, explanatory variables and outcome variables are presented as frequencies and percentages. Since both the outcome variables were dichotomous, binomial logistic regression was applied to predict the incidence of anxiety and depression based on explanatory variables. The alpha level was set at 0.05 for all inferential analyses.

Ethical consideration

This research was complied with the tenets of the Declaration of Helsinki and was approved by the Board of Control (BOC) of Department of Physical Education (T), Guru Nanak Dev University Amritsar, Punjab, India. Informed consent was obtained from each participant.

Results

A total of 247 individuals completed the questionnaires (Table 1). Of the total respondents, 87.4% were female. Most of the respondents (55.1%) were between 35 to 54 years of age. About 1/3 (32.8%) of the respondents were from the healthcare profession. The majority of the respondents (67.6%) were from the United States with the second largest number of respondents from the United Kingdom (12.9%).

Table 1: Baseline parameters of participants (N=247)
| Age             | Frequency | Percent |
|-----------------|-----------|---------|
| Above 65        | 15        | 6.1     |
| Less than 35    | 49        | 19.8    |
| Less than 55    | 136       | 55.1    |
| Less than 65    | 47        | 19.0    |

| Gender          | Frequency | Percent |
|-----------------|-----------|---------|
| Female          | 216       | 87.4    |
| Male            | 31        | 12.6    |

| Occupation      | Frequency | Percent |
|-----------------|-----------|---------|
| Business        | 39        | 15.8    |
| Education       | 34        | 13.8    |
| Healthcare      | 81        | 32.8    |
| Other           | 85        | 34.4    |
| Student         | 8         | 3.2     |

| Demographic characteristics: Country | Frequency | Percent |
|-------------------------------------|-----------|---------|
| United States                       | 167       | 67.6    |
| United Kingdom                      | 32        | 12.9    |
| Australia                           | 2         | 0.8     |
| Europe                              | 17        | 6.8     |
| South America countries             | 5         | 2.0     |
| Other North American countries      | 7         | 2.8     |
| African countries                   | 7         | 2.8     |
| Asian countries                     | 10        | 4.3     |

**Presence of Physical symptoms**

Of the 247 respondents who were infected with novel coronavirus, 212 (85.8%) reported their condition status as negative and 35 (14.2%) reported their condition status as positive. 201 respondents (81.4%) reported that the symptoms were present for more than four weeks. More than half (53.4%) reported that
they had a fear of being infected by COVID-19 for a second time, 3.8% were indifferent and 13.4% had no fear of being re-infected. 58.3% of the total respondents reported that they spent more than 3 hours daily seeking COVID-19 related information. Detailed information on the clinical characteristics of the respondents is presented in Table 2.

Table 2: Clinical characteristics of participants

| Corona positive | Frequency | Percent |
|-----------------|-----------|---------|
| My reports are still positive | 35 | 14.2 |
| Yes, but now my reports are negative | 212 | 85.8 |

| Duration of symptoms | Frequency | Percent |
|----------------------|-----------|---------|
| less than 2 weeks    | 12 | 4.9 |
| Less than 3 weeks    | 17 | 6.9 |
| Less than 4 weeks    | 17 | 6.9 |
| More than 4 weeks    | 201 | 81.4 |

| Fear that you will get COVID again | Frequency | Percent |
|------------------------------------|-----------|---------|
| Maybe                              | 81 | 32.8 |
| No                                 | 34 | 13.8 |
| Yes                                | 132 | 53.4 |

| Daily time spent on COVID related information seeking | Frequency | Percent |
|-------------------------------------------------------|-----------|---------|
| Less than 1 hour                                     | 42 | 17.0 |
| Less than 2 hours                                    | 36 | 14.6 |
| Less than 3 hours                                    | 25 | 10.1 |
| More than 3 hours                                    | 144 | 58.3 |

As shown in Table 3, the symptoms of anxiety as revealed by the GAD-7 scale were observed in 177 (71.7%) of the respondents. Depressive symptoms were present in 241 respondents (97.6%). Only 5 respondents (2%) did not report any psychological problems (anxiety or depression). The presence of both depression and anxiety was reported by 176 (71.3%) respondents. Based on the GAD-score, severe anxiety was present in 100 (40.5%) respondents followed by moderate anxiety in 66 (26.7%) respondents and mild anxiety in 49 (19.8%) respondents. Only 32 (13%) reported no anxiety.

Table 3: Psychological burden in respondents who have had COVID-19 infection
### Presence of Depression (>16)

| Categories       | Frequency | Percent |
|------------------|-----------|---------|
| Absent           | 6         | 2.4     |
| Present          | 241       | 97.6    |

### Presence of any psychological burden (Depression or Anxiety)

| Categories                                      | Frequency | Percent |
|-------------------------------------------------|-----------|---------|
| No depression or anxiety                        | 5         | 2.0     |
| Any psychological issue present                 | 242       | 98.0    |

### Presence of both depression and anxiety

| Categories                                      | Frequency | Percent |
|-------------------------------------------------|-----------|---------|
| Absent                                          | 71        | 28.7    |
| Both depression and anxiety present              | 176       | 71.3    |

### Severity of anxiety (based on GAD-7)

| Categories            | Frequency | Percent |
|-----------------------|-----------|---------|
| No anxiety            | 32        | 13.0    |
| Only mild anxiety     | 49        | 19.8    |
| Moderate anxiety      | 66        | 26.7    |
| Severe anxiety        | 100       | 40.5    |

Results of the logistic regression analyses outline the likelihood of the incidence of anxiety, depression and any psychological disorder (depression or anxiety) based on various predictor variables (Table 4). The variables including younger age range (< 35 years), gender, employment status and time spent seeking COVID-19 related information did not add significantly to the model. However, the duration of COVID-19 related physical symptoms was significantly related to the incidence of anxiety, depression and psychological issues. The patients having shorter duration of COVID-19 related symptoms (< 2 weeks) had better outcomes of experiencing anxiety (OR = 0.19; 95% CI: 0.05 - 0.67) and depression (OR = 0.03; 95% CI: 0.01 - 0.37) than those having longer duration COVID-19 related symptoms.

**Table 4: Logistic regression: Odds ratio for having Psychological issues (Logistic regression analysis)**
| Variables                          | Presence of Anxiety | Presence of Depression | Presence of any psychological issue (Depression or anxiety) |
|-----------------------------------|---------------------|------------------------|-------------------------------------------------------------|
|                                   | Odds Ratio (Exp B)  | p-value                | Odds Ratio (Exp B)  | p-value | Odds Ratio (Exp B)  | p-value |
|                                   | with 95 % CI        |                        | with 95 % CI        |          | with 95 % CI        |          |
| age (years)                       | 0.35 (0.12 - 1.06) | 0.07                   | 0.19 (0.01 - 2.93) | 0.24     | 0.07 (0.01 - 1.70) | 0.10     |
| gender                            | 0.39 (0.13 - 1.16) | 0.09                   | 2.56 (0.27 - 24.21)| 0.41     | 3.09 (0.27 - 35.03)| 0.36     |
| Unemployed                        | 2.25 (0.42 - 12.08)| 0.34                   | 2.58 (0.01 - 3.69) | 0.25     | 5.169 (0.01 - 9.69)| 0.57     |
| Duration of D-19 related symptoms | 0.19 (0.05 - 0.67) | 0.01*                  | 0.03 (0.01 - 0.37) | 0.006*   | 0.02 (0.01 - 0.27) | 0.004*   |
| Less than 3 hours spent VID-19 related information seeking | 1.72 (1.43 - 2.33) | 0.28                   | 1.28 (0.03 - 2.47)| 0.23     | 0.51 (0.04 - 5.65) | 0.47     |

*Statistically significant based on 2-tailed p-value

**Discussion**

Resulting from increases in the COVID-19 pandemic, the World Health Organization has stressed the importance of regularly monitoring and managing the mental health of patients infected with COVID-19 (WHO, 2020). There is evidence regarding the psychological impact of COVID-19 in the general community, however data regarding infected and recovering patients is severely limited (Luo et al., 2020; Varshney et al., 2020). The present study was undertaken to identify any psychological issues that may affect COVID-19 patients. The study focused on two psychological variables: the presence of anxiety disorder and depression. The findings of the study could provide health professionals with important information about the effects and prevalence of anxiety disorder and depression among COVID-19 patients. The data obtained may also be useful in designing and planning interventions for coping with mental health issues in recovering COVID-19 patients.
In our sample, 85.8% had recovered from the infection, yet, 14.2% were still infected with the disease. Our key findings were that signs of anxiety and depression were present in most patients. Also, the prevalence of depression (97.6%) was higher than the prevalence of anxiety (71.7%). Our study shows higher prevalence of both disorders than an earlier web-based study on COVID-19 patients, in which depression and anxiety were present in 21% and 15% patients respectively (Zhang et al., 2020). Prevalence rates of depression and anxiety found in our study are higher than values recorded in a previous study on 144 patients (Kong et al., 2020), and the study reported that age and gender were significant predictors of anxiety and depression in COVID-19 patients. However, in our study logistic regression confirmed that the variables gender, age, employment status and time spent on thinking about COVID-19 were not significantly associated with the incidence of anxiety and depression. The only significant predictor of anxiety and depression was the duration of COVID-19 related physical symptoms. It can be interpreted from the logistic regression results that patients having physical symptoms for more than two weeks were more likely to have incidences of anxiety and depression. The possible causes of these outcomes might be the fear of COVID-19 related death, prolonged isolation or spread of fear and uncertainty through social media. A similar study revealed that anxiety and depressive mood were linked with the loss of smell and taste but not linked with other physical symptoms such as coughing, fever or shortness of breath (Speth et al., 2020).

Limitations and future directions

Our study has some limitations. Firstly, the survey language was English which may be a barrier for some people to participate and understand the survey questions. Moreover, the data does not represent the patients who do not have access to social media and consequently are not social media active. Secondly, no systematic sampling method was used to recruit the participants and therefore the sampled data could contain sampling bias. Also, the sample size of 247 includes 87.4% of females and only 12.6% males. This unevenly distributed sample represents females more than the males. Thirdly, the patients with severe infection could not complete the survey questionnaire. In addition, existing morbidities were not assessed in our survey and these may act as confounding variables and affected study results.

Despite having the number of limitations, to our knowledge, this study is the first of its kind that has used a social media platform to communicate the psychological impact of COVID-19 infection in recovered and recovering patients. Previous studies have surveyed the psychological impact during the COVID-19 lockdown, but those studies were limited to uninfected and general populations (Varshney et al., 2020; Chakraborty and Chatterjee 2020). In future studies, larger and more systematic data collection strategies should be devised to reach a more diverse population; for instance, patients not participating in social media activities. Since this study has reported only initial findings of the psychological impact of patients who have had, and who are recovering from COVID-19, larger systematic assessments will help formulate comprehensive interventions for recovering COVID-19 patients.

Conclusion
Depression and severe anxiety are present in the majority of COVID-19 patients. Longer infection durations of the physical symptoms of COVID-19 significantly increases the likelihood of the incidence of depression and anxiety.

Declarations

Ethical approval: The study was approved by the ethical committee of the Department of Physical Education (T), Guru Nanak Dev University and all methods used in the study involving human participants were in accordance with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Conflicts of interest: We declare that there are no conflicts of interest.

Informed consent: Informed consent was obtained from all individual participants included in the study.
