Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Mathematical analysis of an extended SEIR model of COVID-19 using the ABC-fractional operator

Available online 17 February 2022

Abstract

This paper aims to suggest a time-fractional \( (S\,E\,P\,I\,D\,H\,R) \) model of the COVID-19 pandemic disease in the sense of the Atangana–Baleanu–Caputo operator. The proposed model consists of six compartments: susceptible, exposed, infected (asymptomatic and symptomatic), hospitalized and recovered population. We prove the existence and uniqueness of solutions to the proposed model via fixed point theory. Furthermore, a stability analysis in the context of Ulam–Hyers and the generalized Ulam–Hyers criterion is also discussed. For the approximate solution of the suggested model, we use a well-known and efficient numerical technique, namely the Toufik–Atangana numerical scheme, which validates the importance of arbitrary order derivative \( \vartheta \) and our obtained theoretical results. Finally, a concise analysis of the simulation is proposed to explain the spread of the infection in society.

Keywords: Fractional calculus; COVID-19; Banach contraction mapping principle; Schauder fixed point theorem

1. Introduction

Infectious diseases have been a constant threat to humanity. This threat has increased in recent decades due to the emergence and re-emergence of several lethal infectious diseases. Mathematical analysis and modeling enable officials to comprehend and forecast the dynamics of an infectious disease under several distinct circumstances (see [7,11,17,26,45]).

Fractional calculus is used to examine the effect of memory on computer models, resulting in more accurate results. Due to hereditary characteristics and the notion of memory, fractional calculus is more adaptable than classical calculus. Caputo [28], Liouville–Caputo [13], and Caputo and Fabrizio [12] all put out many ideas on fractional-order operators, and these ideas are highly useful in constructing models for a variety of real-world applications (see [1,3–5,18,20,24,31–33,38] and the references therein). Furthermore, when using numerical approaches and comparing the relationships between different situations, the above-mentioned derivatives have been shown to be highly effective. Many studies have shown that using fractional-order derivatives produces better results.
in obtaining actual data for various models (see [22,34,37,39] and the references therein). Atangana and Baleanu [9] first implemented a new fractional-order derivative in 2016. It was based on the principle of a generalized Mittag-Leffler function in the role of a non-singular and non-local kernel. The newly formulated Atangana–Baleanu (AB) derivative produces better results in many real-world problems (see [10,14,29]).

Coronavirus infection (COVID-19) is a contagious disease that began in December 2019 in China and has since spread worldwide (see [42,43]). The World Health Organization (WHO) named this epidemic on 11 February 2020 as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) (see [15,27]). The WHO announced it as a Public Health Disaster of International Significance on 30 January 2020 (see [44]). As of 11 March 2020, the disease was recorded in more than 118,000 individuals worldwide in 114 nations. Among them, more than 90 percent of infections occurred in only four countries (two of these — China and the Republic of Korea—have dramatically reduced epidemics), and the WHO proclaimed it to be a pandemic, the first triggered by a coronavirus (see [2]). Officially confirmed incidents and deaths on 1st April 2020 were 872,481 and 43,275, respectively, and there was no antidote expressly developed for this strain, with proven efficacy.

The literature includes several mathematical models that aim to explain the dynamics of COVID-19’s development. Three phenomenological models are provided in [30], which have been validated for outbreaks of other diseases other than COVID-19, seeking to produce and test short-term estimates of the total recorded events. Other research (see, e.g., [21]) suggests minor modifications of the SEIR form, including stochastic components.

COVID-19 is a disease triggered by a modern virus that creates a worldwide emergency and requires a model that considers its unique characteristics. In specific, creating a model that integrates the following would be appropriate:

- the impact of undetected infected individuals (see [25]) indicates that COVID-19 is based on the ratio of cases observed overestimated gross infected people;
- the impact of various sanitary and contagious factors on hospitalized individuals (differentiating those with moderate and extreme conditions to survive from others that would ultimately die);
- calculating bed demands in hospitals (one of the main issues confronting policy-makers tackling COVID-19).

The main objective of this research is to study an epidemic fractional-order \( \left( S_p E_p I_p^A I_p^{S_p} H_p R_p \right) \) model, which investigates the significance of COVID-19 spread in society. The paper is organized in the following sections. The derivation of the proposed compartmental model is outlined in Section 2. In Section 3, we presented some basic results related to fractional calculus. The existence and uniqueness of solutions to the proposed COVID-19 fractional-order model are given in Section 4. Section 5 explores some mathematical properties of the fractional model in detail. The proofs of the positivity and boundedness of solutions are done in Section 5. The stability analysis of the proposed model in the form of Ulam–Hyers and generalized Ulam–Hyers has been discussed in Section 6. In the end, we have used a Tofuk–Atangana numerical scheme for the approximate solution of the proposed fractional model.

2. Formulation of the model

The model described here is an update of the SEIR model having two additional compartments. We propose an \( \left( S_p E_p I_p^A I_p^{S_p} H_p R_p \right) \) constituent model, which contains the susceptible, exposed, infected (asymptomatic and symptomatic), hospitalized, and recovered population (see Fig. 1).

Because of this operator’s performance in simulating epidemic diseases and inspired by the practical applications of certain fractional operators in modeling such problems, in this paper, we are investigating the dynamics of the novel coronavirus model in the context of the nonlinear differential equation method involving the Atangana–Baleanu–Caputo (shortly, ABC) fractional derivative. Here, we give the following fractional system:

\[
\begin{align*}
\ABC D^0_{\vartheta} S_p(t) &= \Pi - \frac{S_p(t)}{N} \left( \xi_d^A I_p^A(t) + \xi^{S_p} I_p^{S_p}(t) \right) - d^0 S_p(t), \\
\ABC D^0_{\vartheta} E_p(t) &= \frac{S_p(t)}{N} \left( \xi_d^A I_p^A(t) + \xi^{S_p} I_p^{S_p}(t) \right) - \left( \chi^\vartheta + \kappa_1^\vartheta \right) E_p(t), \\
\ABC D^0_{\vartheta} I_p^A(t) &= \chi \lambda^\vartheta E_p(t) - \left( \gamma_1^\vartheta + \kappa_2^\vartheta \right) I_p^A(t), \\
\ABC D^0_{\vartheta} I_p^{S_p}(t) &= (1 - \chi) \lambda^\vartheta E_p(t) - \left( \gamma_2^\vartheta + \kappa_3^\vartheta \right) I_p^{S_p}(t), \\
\ABC D^0_{\vartheta} H_p(t) &= \gamma_1^\vartheta I_p^A(t) + \gamma_2^\vartheta I_p^{S_p}(t) - \left( \ell^\vartheta + \kappa_4^\vartheta \right) H_p(t), \\
\ABC D^0_{\vartheta} R_p(t) &= \ell^\vartheta H_p(t) - d^0 R_p(t).
\end{align*}
\]
with the initial conditions
\[
\begin{align*}
S_P(0) &= S_{P0}, \\
E_P(0) &= E_{P0}, \\
I_P^A(0) &= I_{P0}, \\
I_P^{SP}(0) &= I_{P0}^{SP}, \\
H_P(0) &= H_{P0}, \\
R_P(0) &= R_{P0},
\end{align*}
\]
(2.2)

where \( \Pi := n \times N \), \( N \) is the total number of individuals and \( n \) is the birth rate, \( ^{ABC}D^\vartheta_0 \) denotes the ABC fractional derivative of order \( \vartheta \in [0, 1) \) and all other parameters are described in Table 1. It is important to note that the model’s parameters are non-negative and having dimensions \( \frac{1}{\text{time}^\vartheta} \).

The total population at time \( t \) is \( N \) which is further divided into \( S_P(t), E_P(t), I_P^A(t), I_P^{SP}(t), H_P(t) \) and \( R_P(t) \). The key assumptions are as follows:

1. natural mortality and birth rates are same;
2. the natural causes of death account for fatalities are presented in compartments \( S_P \) and \( R_P \);
3. the model’s death population is made up of individuals who died as a result of exposure \( \kappa_1^\vartheta E_P(t) \), during infectious period \( (\kappa_2^\vartheta I_P^A(t) \) and \( \kappa_3^\vartheta I_P^{SP}(t) \)) and hospitalization \( \kappa_4^\vartheta H_P(t) \);
4. the total number of dead population from each compartment can be calculated by \( \nu N := d^\vartheta S_P + d^\vartheta R_P + \kappa_1^\vartheta E_P + \kappa_2^\vartheta I_P^A + \kappa_3^\vartheta I_P^{SP} + \kappa_4^\vartheta H_P \);
5. other natural disasters have had a minimal effect on the population; therefore, we are neglecting them.
3. Auxiliary results

The following concepts and proven results would be needed in the sequel.

**Definition 3.1 ([35]).** Let $p \in [1, \infty)$ and $\mathcal{O}$ be an open subset of $\mathbb{R}$, the Sobolev space $H^p(\mathcal{O})$ is defined by

$$H^p(\mathcal{O}) = \{ \Psi \in L^2(\mathcal{O}) : D^\mu \Psi \in L^2(\mathcal{O}), \text{ for all } |\mu| \leq p \}.$$ 

Based on the above definition, Atangana and Baleanu [9] gave the following definition of the Atangana–Baleanu fractional derivative in Caputo sense.

**Definition 3.2 ([9]).** Let $\Psi \in H^1(a, b)$, where $a, b \in \mathbb{R}$ with $a < b$, and $\vartheta \in [0, 1)$. The Atangana and Baleanu fractional derivative in Caputo sense (shorten, $ABC$) are defined as follows:

$$ABC D_\vartheta^\alpha \Psi(t) = \frac{\omega(\vartheta)}{1 - \vartheta} \int_a^t d\varsigma \Psi(\varsigma) \mathbb{E}_\vartheta \left[ \frac{-\vartheta}{1 - \vartheta} (t - \varsigma)^{\alpha} \right] d\varsigma, \quad (3.1)$$

where $\omega$ is the normalization function defined by $\omega(\vartheta) = \frac{\vartheta}{\vartheta - 1}$, for all $0 \leq \vartheta < 1$. Also, $\mathbb{E}_\vartheta$ stands for the Mittag-Leffler function which is a generalization of the exponential function (see [16,23,28]).

**Remark 3.3.** If we replace $\mathbb{E}_\vartheta \left[ \frac{-\vartheta}{1 - \vartheta} (t - \varsigma)^{\alpha} \right]$ by $\mathbb{E}_1 = \exp \left[ \frac{-\vartheta}{1 - \vartheta} (t - \varsigma) \right]$, then we get the so-called Caputo–Fabrizio differential operator. Further, it is to be noted that

$$ABC D_\vartheta^\alpha (\text{Constant}) = 0. \quad (3.2)$$

**Definition 3.4 ([9]).** The Laplace transform of (3.1) is defined as follows:

$$\mathcal{L} \{ ABC D_\vartheta^\alpha \Psi(t) \} (s) = \frac{\omega(\vartheta)}{1 - \vartheta} \mathcal{L} \left[ \int_a^t \frac{1}{\vartheta} \Psi(\varsigma) \mathbb{E}_\vartheta \left[ \frac{-\vartheta}{1 - \vartheta} (t - \varsigma)^{\alpha} \right] d\varsigma \right]$$

$$= \frac{\omega(\vartheta)}{1 - \vartheta} \left[ \frac{s^\alpha \mathcal{L} \{ \Psi(t) \} (s) - s^{\alpha-1} \Psi(0)}{s^\alpha + \frac{s}{1 - \vartheta}} \right], \quad (3.3)$$

**Definition 3.5 ([9]).** Let $\Psi \in H^1(a, b)$, where $a, b \in \mathbb{R}$ with $a < b$, and $\vartheta \in [0, 1)$. The corresponding integral in $ABC$ sense are defined as follows:

$$ABC I_\vartheta^\alpha \Psi(t) = \frac{1 - \vartheta}{\omega(\vartheta)} \Psi(t) + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \int_a^t (t - \varsigma)^{\alpha-1} \Psi(\varsigma) d\varsigma, \quad (3.4)$$

where $\Gamma$ is a gamma function.

**Lemma 3.6.** The solution of the given problem for $0 \leq \vartheta < 1,$

$$ABC D_\vartheta^\alpha \Psi(t) = \sigma(t), \quad t \in [0, T], \quad \Psi(0) = \Psi_0, \quad (3.5)$$
where \( \Psi : [0, T] \to \mathbb{R} \) is an unknown function and \( \Psi_0 \) is a fixed constant, provided by
\[
\Psi(t) = \Psi_0 + \frac{1 - \vartheta}{\omega(\vartheta)} \sigma(t) + \frac{\vartheta}{\omega(\vartheta)} \Gamma(\vartheta) \int_0^t (t - \zeta)^{\varphi-1} \sigma(\zeta)d\zeta. \tag{3.6}
\]

For the qualitative analysis, we define the Banach space \( \mathbb{F} = \mathbb{H} \times \mathbb{H} \times \mathbb{H} \times \mathbb{H} \times \mathbb{H} \times \mathbb{H} \), where \( \mathbb{H} = C[0, T] \) with \( 0 < T < \infty \), under the norm given for \( \Psi = (\psi_1, \psi_2, \psi_3, \psi_4, \psi_5, \psi_6)^T \in \mathbb{F} \) by
\[
\| \Psi \| = \| (\psi_1, \psi_2, \psi_3, \psi_4, \psi_5, \psi_6)^T \|
= \max_{t \in [0, T]} |\psi_1(t)| + |\psi_2(t)| + |\psi_3(t)| + |\psi_4(t)| + |\psi_5(t)| + |\psi_6(t)|.
\]

Throughout this paper, for \( v = (v_1, v_2, \ldots, v_6) \in \mathbb{R}^6 \), we use this notion \(| \cdot |\) as the taxicab norm in \( \mathbb{R}^6 \).

4. Existence and uniqueness of a solution

We shall examine the existence and uniqueness of a solution to our main model (2.1) with the condition (2.2) in this section. Let us write the model (2.1) with the condition (2.2) as
\[
\begin{align*}
\begin{cases}
\ ABC \mathcal{D}_0^\varphi S_P(t) = \Theta_1 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right), \\
\ ABC \mathcal{D}_0^\varphi E_P(t) = \Theta_2 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right), \\
\ ABC \mathcal{D}_0^\varphi I_P^A(t) = \Theta_3 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right), \\
\ ABC \mathcal{D}_0^\varphi I_P^{S_P}(t) = \Theta_4 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right), \\
\ ABC \mathcal{D}_0^\varphi H_P(t) = \Theta_5 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right), \\
\ ABC \mathcal{D}_0^\varphi R_P(t) = \Theta_6 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right),
\end{cases}
\end{align*}
\tag{4.1}
\]
where
\[
\begin{align*}
\Theta_1 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right) &= \Pi - \frac{S_P(t)}{N} \left( \xi_1^0 I_P^A(t) + \xi_2^0 I_P^{S_P}(t) \right) \\
&\quad - d^0 S_P(t), \\
\Theta_2 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right) &= \frac{S_P(t)}{N} \left( \xi_1^0 I_P^A(t) + \xi_2^0 I_P^{S_P}(t) \right) \\
&\quad - (\lambda^0 + \kappa_1^0) E_P(t), \\
\Theta_3 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right) &= \chi \lambda^0 E_P(t) - \left( \gamma_1^0 + \kappa_2^0 \right) I_P^A(t), \\
\Theta_4 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right) &= (1 - \chi) \lambda^0 E_P(t) - \left( \gamma_2^0 + \kappa_3^0 \right) I_P^{S_P}(t), \\
\Theta_5 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right) &= \gamma_1^0 I_P^A(t) + \gamma_2^0 I_P^{S_P}(t) - (\ell^0 + \kappa_4^0) H_P(t), \\
\Theta_6 \left( S_P(t), E_P(t), I_P^A(t), I_P^{S_P}(t), H_P(t), R_P(t) \right) &= \ell^0 H_P(t) - d^0 R_P(t)
\end{align*}
\tag{4.2}
\]
with the condition (2.2). By using (2.1), we transform (4.2) with (2.2) to the following system:
\[
\begin{align*}
\begin{cases}
\ ABC \mathcal{D}_0^\varphi \Psi(t) = Q(t, \Psi(t)), \\
\Psi(0) = \Psi_0,
\end{cases}
\end{align*}
\tag{4.3}
\]
where

\[
\Psi = \begin{bmatrix} S_P \\ E_P \\ I_P^t \\ I_P^{SP} \\ H_P \\ R_P \end{bmatrix}, \quad \text{and} \quad ABC D_0^\alpha \Psi = \begin{bmatrix} ABC D_0^\alpha S_P \\ ABC D_0^\alpha E_P \\ ABC D_0^\alpha I_P^t \\ ABC D_0^\alpha I_P^{SP} \\ ABC D_0^\alpha H_P \\ ABC D_0^\alpha R_P \end{bmatrix}, \quad \Psi_0 = \begin{bmatrix} S_{P0} \\ E_{P0} \\ I_{P0}^t \\ I_{P0}^{SP} \\ H_{P0} \\ R_{P0} \end{bmatrix},
\]

and

\[
Q(t, \Psi(t)) = \begin{bmatrix} \Theta_1 \left( S_P(t), E_P(t), I_P^t(t), I_P^{SP}(t), H_P(t), R_P(t) \right) \\ \Theta_2 \left( S_P(t), E_P(t), I_P^t(t), I_P^{SP}(t), H_P(t), R_P(t) \right) \\ \Theta_3 \left( S_P(t), E_P(t), I_P^t(t), I_P^{SP}(t), H_P(t), R_P(t) \right) \\ \Theta_4 \left( S_P(t), E_P(t), I_P^t(t), I_P^{SP}(t), H_P(t), R_P(t) \right) \\ \Theta_5 \left( S_P(t), E_P(t), I_P^t(t), I_P^{SP}(t), H_P(t), R_P(t) \right) \\ \Theta_6 \left( S_P(t), E_P(t), I_P^t(t), I_P^{SP}(t), H_P(t), R_P(t) \right) \end{bmatrix}.
\]

Using Lemma 3.6, the model (4.3) can be turned to the fractional integral equation in the sense of ABC fractional integral as follows:

\[
\Psi(t) = \Psi_0 + \frac{1 - \vartheta}{o(\vartheta)} Q(t, \Psi(t)) + \frac{\vartheta}{o(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \zeta)^{\vartheta - 1} Q(\zeta, \Psi(\zeta)) \, d\zeta. \tag{4.4}
\]

Here we impose the following conditions:

\((\Delta_1)\) there exist two constants \(p_1 > 0\) and \(p_2 > 0\) such that

\[
|Q(t, \Psi(t))| \leq p_1 \|\Psi\| + p_2,
\]

for all \(t \in [0, T]\).

\((\Delta_2)\) there exists \(p_3 > 0\) such that

\[
|Q(t, \Psi(t)) - Q(t, \tilde{\Psi}(t))| \leq p_3 \left|\Psi(t) - \tilde{\Psi}(t)\right|,
\]

for each \(\Psi, \tilde{\Psi} \in \mathcal{F}\) and \(t \in [0, T]\).

We start with the following result.

**Lemma 4.1.** The operator \(\mathcal{C} : \mathcal{F} \to \mathcal{F}\) are defined in (4.4) is completely continuous.

**Proof.** First, we see that if \(\Psi \in \mathcal{F}\), then \(\mathcal{C} \Psi \in \mathcal{F}\). For each \(\Psi \in D_Z := \{\Psi \in \mathcal{F} : \|\Psi\| \leq Z\}\), we obtain

\[
|(\mathcal{C} \Psi)(t)| \leq \|\Psi_0\| + \frac{1 - \vartheta}{o(\vartheta)} \max_{t \in [0, 1]} |Q(t, \Psi(t))| + \max_{t \in [0, 1]} \frac{\vartheta}{o(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \zeta)^{\vartheta - 1} Q(\zeta, \Psi(\zeta)) \, d\zeta
\]

\[
\leq \|\Psi_0\| + \frac{1 - \vartheta}{o(\vartheta)} (p_1 \|\Psi\| + p_2)
\]

\[
+ \frac{\vartheta}{o(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \zeta)^{\vartheta - 1} (p_1 \|\Psi\| + p_2) \, d\zeta
\]

\[
\leq \|\Psi_0\| + \left\{ \frac{1 - \vartheta}{o(\vartheta)} + \frac{T^\vartheta}{o(\vartheta) \Gamma(\vartheta)} \right\} p_2 + \left\{ \frac{1 - \vartheta}{o(\vartheta)} + \frac{T^\vartheta}{o(\vartheta) \Gamma(\vartheta)} \right\} p_1 \|\Psi\|
\]

\[
< +\infty.
\]
where \( A := \left( \frac{1 - \delta}{\omega(\delta)} + \frac{T^\theta}{\omega(\delta) \Gamma(\theta)} \right) \). This implies that
\[
\| \mathcal{C} \Psi \| \leq +\infty.
\]

Hence, \( \mathcal{C} \) is uniformly bounded on \( D_Z \).

Next, we have to prove that the operator \( \mathcal{C} \) is equicontinuous. For this, let \( \Psi \in D_Z \) and \( t_1, t_2 \in [0, T] \) such that \( t_1 < t_2 \). Then
\[
|\mathcal{C} \Psi (t_2) - \mathcal{C} \Psi (t_1)| \leq \frac{\theta}{\omega(\theta) \Gamma(\theta)} \int_{t_1}^{t_2} (t_2 - \varsigma) \theta^\theta - 1 |\mathcal{Q}(\varsigma, \Psi(\varsigma))| d\varsigma
+ \frac{\theta}{\omega(\theta) \Gamma(\theta)} \int_{0}^{t_1} (t_2 - \varsigma) \theta^\theta - 1 (t_1 - \varsigma) \theta^\theta - 1 |\mathcal{Q}(\varsigma, \Psi(\varsigma))| d\varsigma
\]
\[
\leq \left( p_1 Z + p_2 \right) \left( 2(t_2 - t_1) \theta^\theta + (t_2^\theta - t_1^\theta) \right).
\]
Due to the fact that \( t_1 \to t_2 \), the right hand side of the preceding inequality approaches to zero. As a result of the Arzelà–Ascoli theorem, \( \mathcal{C} \) is compact and therefore completely continuous. \( \square \)

**Theorem 4.2.** Assume that \( \mathcal{Q} : [0, T] \times \mathbb{R}^6 \to \mathbb{R} \) is continuous and (\( \Delta_1 \)) is satisfied. Then the integral Eq. (4.4) which is equivalent to the proposed COVID-19 model (2.1)–(2.2) has at least one solution.

**Proof.** Consider \( \mathcal{S} := \{ \Psi \in \mathbb{F} : \Psi = \delta(\mathcal{C} \Psi)(t), 0 < \delta < 1 \} \). From Lemma 4.1, it is clear that the operator \( \mathcal{C} : \mathcal{S} \to \mathbb{F} \) as given in (4.9) is completely continuous. From (\( \Delta_1 \)), for any \( \Psi \in \mathcal{S} \), we obtain
\[
| \Psi(t) | = | \delta(\mathcal{C} \Psi)(t) |
\]
\[
\leq \| \Psi_0 \| + \frac{1 - \delta}{\omega(\theta)} |\mathcal{Q}(t, \Psi(t))| + \frac{\theta}{\omega(\theta) \Gamma(\theta)} \int_{0}^{t} (t - \varsigma) \theta^\theta - 1 |\mathcal{Q}(\varsigma, \Psi(\varsigma))| d\varsigma
\]
\[
\leq \| \Psi_0 \| + \frac{1 - \delta}{\omega(\theta)} (p_1 \| \Psi \| + p_2) + \frac{\theta}{\omega(\theta) \Gamma(\theta)} \int_{0}^{t} (t - \varsigma) \theta^\theta - 1 (p_1 \| \Psi \| + p_2) d\varsigma
\]
\[
\leq \| \Psi_0 \| + A (p_2 + p_1 \| \Psi \|)
\]
\[
< +\infty,
\]
where \( A := \left( \frac{1 - \delta}{\omega(\theta)} + \frac{T^\theta}{\omega(\delta) \Gamma(\theta)} \right) \). This implies that
\[
\| \Psi \| \leq +\infty.
\]
As a result, \( \mathcal{S} \) is bounded. Hence, the operator has at least one fixed point, which happens to be the solution of the COVID-19 model (2.1)–(2.2). \( \square \)

**Theorem 4.3.** Suppose that \( \Psi \in \mathbb{F} \) and \( \Psi \) maps a bounded subset of \([0, T]\) into relatively compact subset of \( \mathbb{R}^6 \). Then the integral Eq. (4.4) which is equivalent to the proposed model (2.1) with the condition (2.2) has a unique solution provided that \( \tilde{\Lambda}_1, \Lambda p_3 < 1 \), where
\[
A := \left\{ \frac{1 - \delta}{\omega(\theta)} + \frac{T^\theta}{\omega(\delta) \Gamma(\theta)} \right\}, \quad \text{(4.7)}
\]
and
\[
\tilde{\Lambda}_1 := \left\{ \frac{1 - \delta}{\omega(\theta)} + \frac{T^\theta}{\omega(\delta) \Gamma(\theta)} \right\} p_1. \quad \text{(4.8)}
\]

**Proof.** Let the operator \( \mathcal{C} : \mathbb{F} \to \mathbb{F} \) defined for each \( \Psi \in \mathbb{F} \) by
\[
(\mathcal{C} \Psi)(t) = \Psi_0 + \frac{1 - \delta}{\omega(\theta)} \mathcal{Q}(t, \Psi(t)) + \frac{\theta}{\omega(\theta) \Gamma(\theta)} \int_{0}^{t} (t - \varsigma) \theta^\theta - 1 \mathcal{Q}(\varsigma, \Psi(\varsigma)) d\varsigma.
\]
for all $t \in [0, T]$. It can be seen that the operator $C$ is well defined and the unique solution of (4.9) is just the fixed point of $C$. Here, we consider $D_Z = \{ \Psi \in F : \| \Psi \| \leq Z \}$ as a closed and convex set with $Z \geq \frac{\tilde{\Lambda}_2}{1 - \tilde{\Lambda}_1}$, where

$$\tilde{\Lambda}_2 := \| \Psi_0 \| + \left[ \frac{1 - \vartheta}{\omega(\vartheta)} + \frac{T^\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \right] p_2.$$ (4.10)

Thus, it is enough to show that $C D_Z \subset D_Z$. Now, for any $\Psi \in D_Z$, it yields

$$\begin{align*}
|C(\Psi)(t)| & \leq \| \Psi_0 \| + \frac{1 - \vartheta}{\omega(\vartheta)} |Q(t, \Psi(t))| + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \zeta)^{\vartheta - 1} |Q(\zeta, \Psi(\zeta))| d\zeta \\
& \leq \| \Psi_0 \| + \frac{1 - \vartheta}{\omega(\vartheta)} [p_1 \| \Psi \| + p_2] + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \zeta)^{\vartheta - 1} [p_1 \| \Psi \| + p_2] d\zeta \\
& \leq \| \Psi_0 \| + \left[ \frac{1 - \vartheta}{\omega(\vartheta)} + \frac{T^\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \right] p_2 + \left[ \frac{1 - \vartheta}{\omega(\vartheta)} + \frac{T^\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \right] p_1 Z \\
& = \tilde{\Lambda}_2 + \tilde{\Lambda}_1 Z \\
& \leq Z.
\end{align*}$$

Now, let $\Psi_1, \Psi_2 \in F$ and $t \in [0, T]$. Then, we obtain

$$\begin{align*}
|C(\Psi_1(t)) - C(\Psi_2(t))| & \leq \frac{1 - \vartheta}{\omega(\vartheta)} |Q(\zeta, \Psi_1(\zeta)) - Q(\zeta, \Psi_2(\zeta))| \\
& + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \zeta)^{\vartheta - 1} |Q(\zeta, \Psi_1(\zeta)) - Q(\zeta, \Psi_2(\zeta))| d\zeta \\
& \leq \left\{ \frac{1 - \vartheta}{\omega(\vartheta)} + \frac{T^\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \right\} p_3 \| \Psi_1 - \Psi_2 \| \\
& = \Lambda p_3 \| \Psi_1 - \Psi_2 \|.
\end{align*}$$

This implies that

$$\|C(\Psi_1) - C(\Psi_2)\| \leq \Lambda p_3 \| \Psi_1 - \Psi_2 \|.$$ As $\Lambda p_3 < 1$, therefore $C$ is a Banach contraction mapping. Hence, the integral Eq. (4.4) has a unique solution. Consequently, the proposed COVID-19 model (2.1)–(2.2) has a unique solution. $\square$

5. Properties of the model

Here, we discuss some critical aspects of the model (2.1) or, more precisely, the system (4.3), including the boundedness and positivity of the solutions for $t \geq 0$.

5.1. Invariant region

The boundary of solutions for the nonlinear system (2.1) with non-negative initial conditions is determined in this subsection. Our major goal is to prove that the feasible region produced in $\mathbb{R}^6_+$ is positively invariant with respect to the fractional model (2.1).

Theorem 5.1. The feasible region of the proposed fractional model (2.1) is given by

$$\Omega := \left\{ (S_P, E_P, I_P^A, I_P^{SP}, H_P, R_P) \in \mathbb{R}^6_+ : 0 \leq N \leq \frac{H}{v}; \ S_P, E_P, I_P^A, I_P^{SP}, H_P, R_P \geq 0 \right\}$$ (5.1)

The existence and uniqueness of the solution of model (2.1) have already been shown in the preceding section; all that remains is to demonstrate that the set $\Omega$ is positively invariant with respect to the condition (2.2). For the proof of Theorem 5.1, the following theorem will be utilized.

Theorem 5.2. The solutions of the system (2.1) are bounded.
By applying the Laplace transform on both sides of above inequality, we obtain
\[ \mathcal{L} \left[ ABC D^\vartheta_0 N(t) \right] (s) = \frac{I_\vartheta}{s} - \nu \mathcal{L} \left[ N(t) \right] (s) \]
and then
\[ \frac{\omega(\vartheta)s^\vartheta \mathcal{L} \left[ N(t) \right] (s)}{\vartheta + (1 - \vartheta)s^\vartheta} + \nu \mathcal{L} \left[ N(t) \right] (s) = I_\vartheta s^{\vartheta - (\vartheta + 1)} + \frac{\omega(\vartheta)N(0)s^{\vartheta - 1}}{\vartheta + (1 - \vartheta)s^\vartheta}, \]
where \( N(0) \) represents the initial value of the total population and \( \omega \) is the normalization function defined in Definition 3.2. This implies that
\[ \mathcal{L} \left[ N(t) \right] (s) = \frac{I_\vartheta \left[ (1 - \vartheta)s^\vartheta + \vartheta \right] s^{\vartheta - (\vartheta + 1)} + \omega(\vartheta)s^{\vartheta - 1}N(0)}{\nu \vartheta + (1 - \vartheta)s^\vartheta + \omega(\vartheta)s^\vartheta}. \]
Now, by applying the inverse Laplace transform, we have
\[ N(t) = \frac{I_\vartheta \vartheta t^\vartheta}{(1 - \vartheta)v + \omega(\vartheta)}E_{\vartheta, \vartheta + 1}(-\vartheta t^\vartheta) + \left[ \frac{I_\vartheta (1 - \vartheta)}{(1 - \vartheta)v + \omega(\vartheta)} + \frac{\omega(\vartheta)N(0)}{\omega(\vartheta) + (1 - \vartheta)v} \right] E_{\vartheta, 1}(-\vartheta t^\vartheta), \] (5.3)
where \( \vartheta = \frac{\vartheta_w}{\omega(\vartheta)(1 - \vartheta)v} \), and \( E_{a,b} \) is the Mittag-Leffler function with two parameters \( a > 0 \) and \( b > 0 \) may be defined by the following series
\[ E_{a,b}(h) = \sum_{n=0}^{\infty} \frac{h^n}{\Gamma(an + b)}, \]
whose Laplace transform is
\[ \mathcal{L} \left\{ t^{b-1}E_{a,b}(\pm \Lambda t^\vartheta) \right\} = \frac{s^{a-b}}{s^a + \Lambda}, \]
provided that \( s > |\Lambda|^1/a \). For \( a, b > 0 \), the Mittag-Leffler function satisfies
\[ E_{a,b}(h) = \frac{1}{\hbar} \left[ E_{a,b-a}(h) - \frac{1}{\Gamma(b - a)} \right], \]
and for the case \( a = \vartheta, b = \vartheta + 1 \) and \( h = -\vartheta t^\vartheta \), we have
\[ E_{\vartheta, \vartheta + 1}(-\vartheta t^\vartheta) = \frac{1}{\vartheta^\vartheta} \left[ 1 - E_{\vartheta, 1}(-\vartheta t^\vartheta) \right]. \] (5.4)
From [9], it is clear that the Mittag-Leffler function is bounded for all \( t > 0 \) and possess an asymptotic behavior. Therefore, from (5.2) and (5.3), we can say that \( N(t) \leq \frac{I_\vartheta}{\nu} \) as \( t \to \infty \). Thus, \( N(t) \) and all other variables of the model (2.1) are bounded in a region \( \Omega \).

The solution remains \( x = 0 \) for all \( t > 0 \) if \( x_0 = 0 \). Furthermore, for any non-negative set of initial conditions in \( \Omega \), every solution of model (2.1) in
\[ \mathbb{R}^6_+ = \{ y \in \mathbb{R}^6 : y \geq 0 \}, \quad y(t) = \left( S_p, E_p, I^A_p, I^{SP}_p, H_p, R_p \right)^T, \]
approaches asymptotically in finite time \( t \), enters and remains in \( \Omega \). Thus, the closed set \( \Omega \) is positively invariant for our system (2.1). \( \square \)

### 5.2. Positivity of solutions

In this subsection, we will show that for all \( t \geq 0 \), the state variables \( S_p, E_p, I^A_p, I^{SP}_p, H_p, R_p \) are positive. This characteristic is essential in order to demonstrate that our model is physically feasible.
5.3. Equilibrium points

Theorem 5.3. The solution space \((S_P, E_P, I_P^A, I_P^{Sp}, H_P, R_P)\) of the system (2.1) will remain positive forever with any non-negative initial data.

Proof. First equation of the model (2.1) is rearranged to give

\[
\frac{ABC}{\partial}D_0^0 S_P(t) \geq -\left(1 + \xi_A \frac{I_P^A(t)}{N} + \xi_{Sp} \frac{I_P^{Sp}(t)}{N} \right) S_P(t).
\]

As all the solutions are bounded, therefore, we let \(\frac{I_P^A(t)}{N}\) and \(\frac{I_P^{Sp}(t)}{N}\) are bounded by \(\rho_1\) and \(\rho_2\) respectively. Then,

\[
\frac{ABC}{\partial}D_0^0 S_P(t) \geq -q S_P(t), \tag{5.5}
\]

where \(q := \xi_A \rho_1 + \xi_{Sp} \rho_2 + d\) is a constant. Applying the Laplace transform on both sides of (5.5), we obtain

\[
\frac{\omega(\vartheta) s^\vartheta}{\vartheta + (1 - \vartheta)s^\vartheta} \mathcal{L}\{S_P(t)\}(s) = \frac{\omega(\vartheta) s^\vartheta}{\vartheta + (1 - \vartheta)s^\vartheta} S_P(0) + \frac{s^\vartheta - 1}{s^\vartheta} \frac{q s^\vartheta}{\omega(\vartheta) + q(1 - \vartheta)}.
\]

and

\[
\mathcal{L}\{S_P(t)\}(s) \geq \frac{\omega(\vartheta) s^\vartheta - 1}{\omega(\vartheta) + q(1 - \vartheta)} S_P(0) + \frac{s^\vartheta - 1}{s^\vartheta} \frac{q s^\vartheta}{\omega(\vartheta) + q(1 - \vartheta)}.
\]

Now, by applying the inverse Laplace transform, we have

\[
S_P(t) \geq \frac{\omega(\vartheta) s^\vartheta - 1}{\omega(\vartheta) + q(1 - \vartheta)} E_{\vartheta,1} \left(-\frac{q s^\vartheta}{\omega(\vartheta) + q(1 - \vartheta)}\right) \tag{5.6}
\]

Because both of the values on the right-hand side of (5.6) are positive. Therefore, for every \(t \geq 0\), the solution \(S_P(t)\) also remains positive. Likewise, for every \(t \geq 0\) corresponding to any non-negative initial data, we can simply argue that \(E_P > 0, I_P^A > 0, I_P^{Sp} > 0, H_P > 0, R_P > 0\). As a result, the solutions in \(\mathbb{R}^6_+\) will always be positive. \(\square\)

5.3. Equilibrium points

Here, by solving the following system yields the equilibrium points of the suggested fractional model (2.1):

\[
\frac{ABC}{\partial}D_0^0 S_P = \frac{ABC}{\partial}D_0^0 E_P = \frac{ABC}{\partial}D_0^0 I_P^A = \frac{ABC}{\partial}D_0^0 I_P^{Sp} = \frac{ABC}{\partial}D_0^0 H_P = \frac{ABC}{\partial}D_0^0 R_P = 0.
\]

The proposed model (2.1) has a unique non-negative Corona free equilibrium at the point after simple computations given by

\[
E_P^0 = \left(S_{P0}, E_{P0}^*, I_{P0}^A, I_{P0}^{Sp}, H_{P0}, R_{P0}\right) = \left(\frac{1}{\nu}, 0, 0, 0, 0\right),
\]

and a unique non-negative Corona present equilibrium at the point given by

\[
E_P^* = \left(S_{P1}^*, E_{P1}^*, I_{P1}^A, I_{P1}^{Sp}, H_{P1}^*, R_{P1}\right),
\]

in the epidemiological region \(\Omega\), where

\[
S_{P1}^* = \frac{S_{P0}}{R_{P0}} > 0, \quad E_{P1}^* = \left(\frac{R_{P0}^* - 1}{R_{P0}^*}\right) \left(\frac{d^\vartheta S_{P0}^*}{R_{P0}^* (\lambda^\vartheta + \kappa_1^\vartheta)}\right) > 0, \quad I_{P1}^A = \left(\frac{R_{P0}^* - 1}{R_{P0}^*}\right) \left(\frac{d^\vartheta \chi \lambda^\vartheta S_{P0}^*}{R_{P0}^* (\lambda^\vartheta + \kappa_1^\vartheta)}\right) (\gamma_1^\vartheta + \kappa_2^\vartheta) > 0, \quad I_{P1}^{Sp} = \left(\frac{R_{P0}^* - 1}{R_{P0}^*}\right) \left(\frac{d^\vartheta (1 - \chi) \lambda^\vartheta S_{P0}^*}{R_{P0}^* (\lambda^\vartheta + \kappa_1^\vartheta)}\right) (\gamma_2^\vartheta + \kappa_3^\vartheta) > 0.
\]
5.4. Threshold parameter $R_0$

The value of the threshold parameter, commonly represented by $R_0$, can be used to define the dynamics of mathematical models. Any infectious disease spreads when an infected individual comes into contact with a group of entirely susceptible persons. As a result, at the time $t \geq 0$, a threshold parameter refers to the total number of new infections created by an infected individual. It secretly predicts a model’s dynamical behavior, indicating that it gives more excellent knowledge regarding the disease’s future spread or containment.

The value of the threshold parameter in model (2.1) is determined using the conventional next generation matrix technique. If $v = (v_1, v_2, v_3, v_4) = \left( E_p, I_p^A, I_p^E, H_p \right)^T \in \mathbb{R}_+^4$, then the model (2.1) can be written as

$$A^{BC}_0 \mathbf{v}_i = F_i(v) - G_i(v), \quad i = 1(1)4,$$

where $F_i(v)$ represents the rate of appearance of new infections in compartment $i$ and $G_i(v)$ denotes the rate of transfer of infections to and from compartment $i$.

Now, by taking the Jacobian of the matrices at point $E P_0^*$, we have

$$\mathbf{F} = \begin{bmatrix}
\frac{\partial F_1}{\partial E_p} & \frac{\partial F_1}{\partial I_p^A} & \frac{\partial F_1}{\partial I_p^E} & \frac{\partial F_1}{\partial H_p} \\
\frac{\partial F_2}{\partial E_p} & \frac{\partial F_2}{\partial I_p^A} & \frac{\partial F_2}{\partial I_p^E} & \frac{\partial F_2}{\partial H_p} \\
\frac{\partial F_3}{\partial E_p} & \frac{\partial F_3}{\partial I_p^A} & \frac{\partial F_3}{\partial I_p^E} & \frac{\partial F_3}{\partial H_p} \\
\frac{\partial F_4}{\partial E_p} & \frac{\partial F_4}{\partial I_p^A} & \frac{\partial F_4}{\partial I_p^E} & \frac{\partial F_4}{\partial H_p}
\end{bmatrix} = \begin{bmatrix}
0 & \xi_A^\theta & \xi_{Sp}^\theta & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix},$$

$$\mathbf{G} = \begin{bmatrix}
\frac{\partial G_1}{\partial E_p} & \frac{\partial G_1}{\partial I_p^A} & \frac{\partial G_1}{\partial I_p^E} & \frac{\partial G_1}{\partial H_p} \\
\frac{\partial G_2}{\partial E_p} & \frac{\partial G_2}{\partial I_p^A} & \frac{\partial G_2}{\partial I_p^E} & \frac{\partial G_2}{\partial H_p} \\
\frac{\partial G_3}{\partial E_p} & \frac{\partial G_3}{\partial I_p^A} & \frac{\partial G_3}{\partial I_p^E} & \frac{\partial G_3}{\partial H_p} \\
\frac{\partial G_4}{\partial E_p} & \frac{\partial G_4}{\partial I_p^A} & \frac{\partial G_4}{\partial I_p^E} & \frac{\partial G_4}{\partial H_p}
\end{bmatrix} = \begin{bmatrix}
\lambda^\theta + \kappa_1^\theta & 0 & 0 & 0 \\
-\lambda^\theta & \gamma_1^\theta + \kappa_2^\theta & 0 & 0 \\
-\lambda^\theta (1 - \chi) & 0 & \gamma_2^\theta + \kappa_3^\theta & 0 \\
0 & -\gamma_1^\theta & -\gamma_2^\theta & \ell^\theta + \kappa_4^\theta
\end{bmatrix}.$$ 

The maximum absolute eigenvalue of the positive matrix $\mathbf{FG}^{-1}$ is the value of $R_0$ for the model (2.1). That is,

$$R_0 = \frac{\chi \xi_A^\theta (\gamma_2^\theta + \kappa_3^\theta) + (1 - \chi) \xi_{Sp}^\theta (\gamma_1^\theta + \kappa_2^\theta)}{(\lambda^\theta + \kappa_1^\theta) (\gamma_1^\theta + \kappa_2^\theta) (\gamma_2^\theta + \kappa_3^\theta)} \lambda^\theta.$$ 

5.5. Strength number $A_0$

The strength number is the expansion of the reproduction number. Without a doubt, the reproduction rate is critical in the study of epidemiology when it comes to the spread and extinction of diseases. The epidemiologist uses a variety of strategies to get such numbers (i.e., violation of the reproduction number’s uniqueness and many others). The primary conclusion of this strategy depends on the prediction of the waves of the transmission of illness. The essential point is that this number is evaluated using the next-generation matrix approach by assuming coronavirus-free equilibrium in the system (2.1) and calculating the second derivative of infectious classes. As a
result, the transmission and transition matrices are denoted by F and G [8], respectively, where:

\[
\begin{bmatrix}
\frac{a^2 F_1}{\partial E_p} & \frac{a^2 F_1}{\partial I_{p1}} & \frac{a^2 F_1}{\partial I_{p2}} & \frac{a^2 F_1}{\partial H_p} \\
\frac{a^2 F_2}{\partial E_p} & \frac{a^2 F_2}{\partial I_{p1}} & \frac{a^2 F_2}{\partial I_{p2}} & \frac{a^2 F_2}{\partial H_p} \\
\frac{a^2 F_3}{\partial E_p} & \frac{a^2 F_3}{\partial I_{p1}} & \frac{a^2 F_3}{\partial I_{p2}} & \frac{a^2 F_3}{\partial H_p} \\
\frac{a^2 F_4}{\partial E_p} & \frac{a^2 F_4}{\partial I_{p1}} & \frac{a^2 F_4}{\partial I_{p2}} & \frac{a^2 F_4}{\partial H_p}
\end{bmatrix}
= \begin{bmatrix}
0 & -\frac{\epsilon}{N^2} & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}.
\]

Then

\[
\text{Det} \left( \tilde{F}G^{-1} - \theta I_4 \right) = 0.
\]

Hence, the strength number \( A_0 \) is

\[
A_0 = \left( -\lambda^0 \right) \left( \frac{1}{N^2} \left( \frac{\chi \xi^0 \left( 2 + \kappa_1 \right) + \left( 1 - \chi \right) \xi^0 \left( 2 + \kappa_2 \right)}{\left( \lambda^0 + \kappa_1 \right) \left( \gamma_1^0 + \kappa_2 \right) \left( \gamma_2^0 + \kappa_3 \right)} \right) \right) < 0.
\]

A negative strength number indicates that the system (2.1) will have a single magnitude, either a maximum with two infection sites suggesting a single wave or a quick drop from the coronavirus-free equilibrium. As a result, the infection will grow to a minimal point with the renewal process, then stabilize or halt as requested later.

6. Stability results

The consistency of solutions has a strong emphasis on the theory of mathematical modeling. For illustration, slight variations in the model, induced by natural measurement errors in practical situations, have a minor proportional impact on the solution. The mathematical calculations that explain the system will not accurately forecast the probable result. Hence, the stability of the suggested mathematical model (2.1) with (2.2) must be discussed here. For the detail of the Ulam–Hyers and generalized Ulam–Hyers stability, we refer [6,19,40,41].

The definitions that follow are required in the upcoming results. Let \( \epsilon > 0 \) and consider the following inequality:

\[
\left| \int_0^T \hat{Q}(t) \psi(t) \right| \leq \epsilon, \quad t \in [0, T], \quad (6.1)
\]

where \( \epsilon = \max \left( \epsilon_j \right)^T, \quad j = 1, 2, \ldots, 6. \)

Definition 6.1. The proposed problem (3.5), which is equivalent to model (2.1)–(2.2), is Ulam–Hyers stable if there exists \( \Xi > 0 \) such that, for every \( \epsilon > 0 \) and for each solution \( \hat{\psi} \in \mathbb{F} \) satisfying inequality (6.1), there exists a solution \( \psi \in \mathbb{F} \) of problem (4.3) with the initial condition \( \hat{\psi}(0) = \psi(0) \) such that

\[
\left| \psi(t) - \hat{\psi}(t) \right| \leq \Xi \epsilon, \quad t \in [0, T],
\]

where

\[
\hat{\psi} = \begin{bmatrix}
\hat{S}_p \\
\hat{E}_p \\
\hat{I}_p^A \\
\hat{I}_p^{Sp} \\
\hat{P}_p \\
\hat{H}_p \\
\hat{R}_p
\end{bmatrix}, \quad \psi_0 = \begin{bmatrix}
\hat{S}_{p0} \\
\hat{E}_{p0} \\
\hat{I}_{p0}^A \\
\hat{I}_{p0}^{Sp} \\
\hat{P}_{p0} \\
\hat{H}_{p0} \\
\hat{R}_{p0}
\end{bmatrix}, \quad \Xi = \max \left( \Xi_j \right), \quad \epsilon = \max \left( \epsilon_j \right)
\]

\[
\Xi = \begin{bmatrix}
\Xi_1 \\
\Xi_2 \\
\Xi_3 \\
\Xi_4 \\
\Xi_5 \\
\Xi_6 \\
\Xi_7
\end{bmatrix}, \quad \epsilon = \begin{bmatrix}
\epsilon_1 \\
\epsilon_2 \\
\epsilon_3 \\
\epsilon_4 \\
\epsilon_5 \\
\epsilon_6
\end{bmatrix}
\]

\[
76
\]
ϕ

Problem (4.3), which is equivalent to the model (2.1) with (2.2), is referred to as being generalized Ulam–Hyers stable if there exists a continuous function ϕ : R+ → R+ with ϕ(0) = 0 such that for each solution ⃗Ψ ∈ F of the inequality (6.1), there exists a solution ̃Ψ ∈ F of Problem (4.3) such that

\[ |\tilde{Ψ}(t) - Ψ(t)| \leq ϕε, \quad t \in [0, T], \]

where ϕ = max \( (ϕ_j)_T \), j = 1, 2, . . . , 6.

Assumption 6.3. Consider a small perturbation h ∈ C[0, T] such that h(0) = 0 with the following properties:

(i) |h(t)| ≤ ε, h = max \( (h_j)_T \), t ∈ [0, T] and ε > 0;

(ii) for t ∈ [0, T], we have the following model

\[ A^{BC} D_0^\alpha \tilde{Ψ}(t) = Q \left( t, \tilde{Ψ}(t) \right) + h(t), \]

where h(t) = (h_1(t), h_2(t), . . . , h_6(t))^T.

Lemma 6.4. The solution of the perturbed problem

\[
\begin{align*}
\left\{ \begin{array}{l}
A^{BC} D_0^\alpha \tilde{Ψ}(t) = Q \left( t, \tilde{Ψ}(t) \right) + h(t), \\
\tilde{Ψ}(0) = \tilde{Ψ}_0,
\end{array} \right.
\end{align*}
\]

satisfies the given relation

\[ |\tilde{Ψ}_h(t) - \tilde{Ψ}(t)| \leq Λε, \]

where \( \tilde{Ψ}_h(t) \) is a solution of (6.2), \( \tilde{Ψ}(t) \) satisfies (6.1) and \( Λ := \left( \frac{1 - ω(\vartheta)}{ω(\vartheta)} + \frac{Γ(\vartheta)}{ω(\vartheta)Γ(\vartheta)} \right). \)

Proof. In view of (ii) of Assumption 6.3 and Lemma 3.6, the solution of (6.2) is given by

\[
\begin{align*}
\tilde{Ψ}_h(t) &= \tilde{Ψ}_0 + \frac{1 - \vartheta}{ω(\vartheta)} Q \left( t, \tilde{Ψ}(t) \right) + \frac{\vartheta}{ω(\vartheta)Γ(\vartheta)} \int_0^t (t - ζ)^{\vartheta - 1} Q \left( \tilde{Ψ}(\zeta) \right) dζ \\
&+ \frac{1 - \vartheta}{ω(\vartheta)} h(t) + \frac{\vartheta}{ω(\vartheta)Γ(\vartheta)} \int_0^t (t - ζ)^{\vartheta - 1} h(\zeta) dζ.
\end{align*}
\]

Furthermore, we have

\[
\begin{align*}
\tilde{Ψ}(t) &= \tilde{Ψ}_0 + \frac{1 - \vartheta}{ω(\vartheta)} Q \left( t, \tilde{Ψ}(t) \right) + \frac{\vartheta}{ω(\vartheta)Γ(\vartheta)} \int_0^t (t - ζ)^{\vartheta - 1} Q \left( \tilde{Ψ}(\zeta) \right) dζ.
\end{align*}
\]
Using (i) of Assumption 6.3, we get
\[ \left| \tilde{\Psi}_h(t) - \tilde{\Psi}(t) \right| \leq \frac{1 - \vartheta}{\omega(\vartheta)} |h(t)| + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \zeta)^{\vartheta - 1} |h(\zeta)| \, d\zeta \]
\[ \leq \left( \frac{1 - \vartheta}{\omega(\vartheta)} + \frac{T^\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \right) \epsilon = \Lambda \epsilon, \]
where \( \Lambda := \left( \frac{1 - \vartheta}{\omega(\vartheta)} + \frac{T^\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \right). \)
This implies that
\[ \left| \tilde{\Psi}_h(t) - \tilde{\Psi}(t) \right| \leq \Lambda \epsilon. \]
Hence, we get the desired result. \( \square \)

**Theorem 6.5.** Under the assumptions of Theorem 4.3, the model (2.1)–(2.2) is Ulam–Hyers and, consequently, generalized Ulam–Hyers stable.

**Proof.** Suppose that \( \tilde{\Psi} \in \mathbb{F} \) satisfies inequality (6.1) and \( \Psi \in \mathbb{F} \) is a unique solution of problem (4.4) with the condition
\[ \Psi(0) = \tilde{\Psi}(0). \] (6.3)

Due to (6.3), we can write (4.4) as
\[ \Psi(t) = \tilde{\Psi}(0) + \frac{1 - \vartheta}{\omega(\vartheta)} Q(t, \tilde{\Psi}(t)) + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \varsigma)^{\vartheta - 1} Q(\varsigma, \Psi(\varsigma)) \, d\varsigma. \]

Thus, by (\( \Delta_1 \)) and Lemma 6.4, we obtain
\[ \left| \tilde{\Psi}_h(t) - \Psi(t) \right| \leq \left| \tilde{\Psi}_h(t) - \tilde{\Psi}(t) \right| + \left| \tilde{\Psi}(t) - \Psi(t) \right| \]
\[ \leq \Lambda \epsilon + \frac{1 - \vartheta}{\omega(\vartheta)} \left| Q(t, \tilde{\Psi}(t)) - Q(t, \Psi(t)) \right| + \Lambda \epsilon \]
\[ + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \int_0^t (t - \varsigma)^{\vartheta - 1} \left| Q(\varsigma, \tilde{\Psi}(\varsigma)) - Q(\varsigma, \Psi(\varsigma)) \right| \, d\varsigma \]
\[ \leq 2\Lambda \epsilon + \left( \frac{1 - \vartheta}{\omega(\vartheta)} + \frac{T^\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \right) p_3 \left\| \tilde{\Psi} - \Psi \right\| \]
\[ = 2\Lambda \epsilon + \Lambda p_3 \left\| \tilde{\Psi} - \Psi \right\|. \]

Hence,
\[ \left\| \tilde{\Psi} - \Psi \right\| \leq \frac{2\Lambda \epsilon}{1 - \Lambda p_3}. \]

As, \( \Lambda p_3 < 1 \), we obtain
\[ \left\| \tilde{\Psi} - \Psi \right\| \leq \Xi \epsilon, \]
where \( \Xi := \frac{2\Lambda}{1 - \Lambda p_3}. \) \( \square \)

**Remark 6.6.** If we set \( \varphi(\epsilon) = \Xi \epsilon \) such that \( \varphi(0) = 0 \), then from the above theorem, we conclude that the proposed model (2.1) with (2.2) is generalized Ulam–Hyers stable.
The system (2.1) may be represented using the fundamental theorem of fractional calculus.

The theoretical models are then obtained by employing the current scheme. The ABC fractional derivative is utilized to develop the computational procedure for the simulation of our model (2.1).

7. Numerical simulations and discussion

In this section, we need to examine the estimated solutions of the ABC fractional-order model (2.1) with (2.2).

The system (2.1) may be represented using the fundamental theorem of fractional calculus.

\[
z(t) - z(0) = \frac{1 - \vartheta}{\omega(\vartheta)} \Psi(t, z(t)) + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \int_{0}^{t} (t - \varsigma)^{\vartheta - 1} \Psi(\varsigma, z(\varsigma)) d\varsigma,
\]

At \( t = t_{n+1}, \ n = 0, 1, 2, \ldots, N \) with \( h = \frac{T}{N} \), we have

\[
z(t_{n+1}) = z(0) + \frac{1 - \vartheta}{\omega(\vartheta)} \Psi(t_{n}, z(t_{n})) + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \sum_{j=0}^{n} \left[ \frac{\Psi(t_{j}, z(t_{j}))}{h} \times \right.

\[
\int_{t_{j}}^{t_{j+1}} (t_{n+1} - t)^{\vartheta - 1} (t - t_{j-1}) dt - \frac{\Psi(t_{j-1}, z(t_{j-1}))}{h} \times \frac{1}{\Gamma(\vartheta + 2)} \left. \right] (t_{n+1} - t)^{\vartheta - 1} (t - t_{j}) dt.
\]

Finally, we get the approximate solution as:

\[
z(t_{n+1}) = z(t_{0}) + \frac{1 - \vartheta}{\omega(\vartheta)} \Psi(t_{n}, z(t_{n})) + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta)} \sum_{j=0}^{n} \left[ \frac{h^{\vartheta} \Psi(t_{j}, z(t_{j}))}{\Gamma(\vartheta + 2)} \times \right.

\[
\left. \{ (n - j + 2 + \vartheta)(n + 1 - j)^{\vartheta - 1} (n - j + 2 + 2 \vartheta)(n - j)^{\vartheta} \right] 

\[
- \frac{h^{\vartheta} \Psi(t_{j-1}, z(t_{j-1}))}{\Gamma(\vartheta + 2)} \left. \right] (n + 1 - j)^{\vartheta + 1} - (n - j + 1 + \vartheta)(n - j)^{\vartheta} \left. \right] \right]

\]

Hence, we obtain the following recursive formula for the model equations:

\[
S_{p}(t_{n+1}) = S_{p}(t_{0}) + \frac{1 - \vartheta}{\omega(\vartheta)} \Psi_{1}(t_{n}, z(t_{n})) + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta + 2)} \sum_{j=0}^{n} \left[ \frac{h^{\vartheta} \Psi_{1}(t_{j}, z(t_{j}))}{\Gamma(\vartheta + 2)} \times \right.

\[
\left. \{ (n - j + 2 + \vartheta)(n + 1 - j)^{\vartheta - 1} (n - j + 2 + 2 \vartheta)(n - j)^{\vartheta} \right] 

\[
- \frac{h^{\vartheta} \Psi_{1}(t_{j-1}, z(t_{j-1}))}{\Gamma(\vartheta + 2)} \left. \right] (n + 1 - j)^{\vartheta + 1} - (n - j + 1 + \vartheta)(n - j)^{\vartheta} \left. \right] \right]

\]

\[
E_{p}(t_{n+1}) = E_{p}(t_{0}) + \frac{1 - \vartheta}{\omega(\vartheta)} \Psi_{2}(t_{n}, z(t_{n})) + \frac{\vartheta}{\omega(\vartheta) \Gamma(\vartheta + 2)} \sum_{j=0}^{n} \left[ \frac{h^{\vartheta} \Psi_{2}(t_{j}, z(t_{j}))}{\Gamma(\vartheta + 2)} \times \right.

\[
\left. \{ (n - j + 2 + \vartheta)(n + 1 - j)^{\vartheta - 1} (n - j + 2 + 2 \vartheta)(n - j)^{\vartheta} \right] 

\[
- \frac{h^{\vartheta} \Psi_{2}(t_{j-1}, z(t_{j-1}))}{\Gamma(\vartheta + 2)} \left. \right] (n + 1 - j)^{\vartheta + 1} - (n - j + 1 + \vartheta)(n - j)^{\vartheta} \left. \right] \right]

\]
7.2. Results and discussion

This portion includes a computational simulation of the transmission dynamics of COVID-19 in society. To this end, the initial conditions are posited as $S_P(0) = 600$, $I_P^t(0) = 90$, and $I_P^{S_P}(0) = 40$. Here, for the

\begin{align}
I_P^t(t_{n+1}) &= I_P^t(t_0) + \frac{1 - \vartheta}{\omega(t)} \Psi_3(t_n, z(t_n)) + \frac{\vartheta}{\omega(t)} \sum_{j=0}^{n} \left( \frac{h^\vartheta \Psi_4(t_j, z(t_j))}{\Gamma(\vartheta + 2)} \times \right.
\left. \{ (n - j + 2 + \vartheta)(n + 1 - j)^\vartheta (n - j + 2 + 2\vartheta)(n - j)^\vartheta \} 
- \frac{h^\vartheta \Psi_1(t_{j-1}, z(t_{j-1}))}{\Gamma(\vartheta + 2)} \{ (n + 1 - j)^{\vartheta + 1} - (n - j + 1 + \vartheta)(n - j)^\vartheta \} \right), \\
I_P^{S_P}(t_{n+1}) &= I_P^{S_P}(t_0) + \frac{1 - \vartheta}{\omega(t)} \Psi_4(t_n, z(t_n)) + \frac{\vartheta}{\omega(t)} \sum_{j=0}^{n} \left( \frac{h^\vartheta \Psi_4(t_j, z(t_j))}{\Gamma(\vartheta + 2)} \times \right.
\left. \{ (n - j + 2 + \vartheta)(n + 1 - j)^\vartheta (n - j + 2 + 2\vartheta)(n - j)^\vartheta \} 
- \frac{h^\vartheta \Psi_1(t_{j-1}, z(t_{j-1}))}{\Gamma(\vartheta + 2)} \{ (n + 1 - j)^{\vartheta + 1} - (n - j + 1 + \vartheta)(n - j)^\vartheta \} \right), \\
H_P(t_{n+1}) &= H_P(t_0) + \frac{1 - \vartheta}{\omega(t)} \Psi_5(t_n, z(t_n)) + \frac{\vartheta}{\omega(t)} \sum_{j=0}^{n} \left( \frac{h^\vartheta \Psi_5(t_j, z(t_j))}{\Gamma(\vartheta + 2)} \times \right.
\left. \{ (n - j + 2 + \vartheta)(n + 1 - j)^\vartheta (n - j + 2 + 2\vartheta)(n - j)^\vartheta \} 
- \frac{h^\vartheta \Psi_1(t_{j-1}, z(t_{j-1}))}{\Gamma(\vartheta + 2)} \{ (n + 1 - j)^{\vartheta + 1} - (n - j + 1 + \vartheta)(n - j)^\vartheta \} \right), \\
R_P(t_{n+1}) &= R_P(t_0) + \frac{1 - \vartheta}{\omega(t)} \Psi_6(t_n, z(t_n)) + \frac{\vartheta}{\omega(t)} \sum_{j=0}^{n} \left( \frac{h^\vartheta \Psi_6(t_j, z(t_j))}{\Gamma(\vartheta + 2)} \times \right.
\left. \{ (n - j + 2 + \vartheta)(n + 1 - j)^\vartheta (n - j + 2 + 2\vartheta)(n - j)^\vartheta \} 
- \frac{h^\vartheta \Psi_1(t_{j-1}, z(t_{j-1}))}{\Gamma(\vartheta + 2)} \{ (n + 1 - j)^{\vartheta + 1} - (n - j + 1 + \vartheta)(n - j)^\vartheta \} \right). 
\end{align}

7.2. Results and discussion

Fig. 2. The graph illustrating the approximate solution for the susceptible class $(S_P)$ at different fractional values of $\vartheta$. 
model’s parameters, we choose $\varepsilon_A^\vartheta = 1 \times 10^{-10}, \varepsilon_S^\vartheta = 1.2312, \lambda^\vartheta = 9.9618 \times 10^{-3}, \kappa_1^\vartheta = 3.3491 \times 10^{-3}, \kappa_2^\vartheta = 1 \times 10^{-10}, \kappa_3^\vartheta = 3.0859 \times 10^{-4}, \kappa_4^\vartheta = 2.1222 \times 10^{-5}, \chi = 1.5683 \times 10^{-1}, \gamma_1^\vartheta = 2.6628 \times 10^{-2}, \gamma_2^\vartheta = 1, \bar{\epsilon}^\vartheta = 6.170 \times 10^{-3}$.

In the following Figs. 2–7, by using a MATLAB package, we create an algorithm to simulate the effects of different parameters corresponding to various fractional values of $\vartheta$. We presented numerical data of 90 days. As you can see in Figs. 2–7, the parameters have different impacts but demonstrate the same behavior in different proportions of $\vartheta$. Figs. 2 and 3 indicate that over time $t$, $S_P(t)$, and $E_P(t)$ (increase and decrease) hit the equilibrium point. It means the susceptible individuals will expand over time, while the exposed population will decline. It is apparent from Figs. 4 and 5 that, with time, the affected community (asymptomatic $I_A^\vartheta(t)$ and symptomatic $I_P^\vartheta(t)$) hits their stable points. As COVID-19 infection cases initially rose, the amount of hospitalized patients $H_P(t)$ was higher (as seen in Fig. 6), although it would decrease with time. Also, the number of COVID-19 contaminated classes decreases over time; therefore, the recovered class $R_P(t)$ eventually decreases (see Fig. 7).
8. Conclusion

In this work, we developed a fractional-order \((S_P E_P I_P^A I_P^S H_P R_P)\) model to examine the dynamics of a new Coronavirus infection. We employed the Atangana–Baleanu derivative operator with the generalized Mittag-Leffler function to formulate the suggested fractional model. Due to its non-local and non-singular kernel, the Atangana–Baleanu derivative operator was selected. Our study’s objective was to concentrate on an \((S_P E_P I_P^A I_P^S H_P R_P)\) model that accurately depicted the predominant properties of the Coronavirus. The fixed point theorems were used to verify the existence and uniqueness of the solution to the suggested fractional model. The basic reproduction number and strength number were calculated theoretically and numerically to account for the model’s dynamical behavior. Also, we developed some results about the qualitative theory and Ulam–Hyers stability analysis. Additionally, we calculated numerical solutions for the given model using an efficient method. Graphic representations had created to verify the dynamic behavior of the solution using Matlab. The results collected are critical in explaining the present dynamics of the COVID-19 epidemic. Moreover, it can be seen that the fractional calculus can explain the
population’s dynamics more concisely. The studies reported may be more efficient with the current outbreak and use preventive measures to mitigate infection. The suggested framework may be utilized in the future to explore other nonlinear fractional differential problems using the $ABC$ fractional derivative.
