Induced \(p\)-wave superfluidity in strongly interacting imbalanced Fermi gases

Kelly R. Patton* and Daniel E. Sheehy†

(Dated: November 19, 2010)

The induced interaction among the majority spin species, due to the presence of the minority species, is computed for the case of a population-imbalanced resonantly-interacting Fermi gas. It is shown that this interaction leads to an instability, at low temperatures, of the recently observed polaron Fermi liquid phase of strongly imbalanced Fermi gases to a \(p\)-wave superfluid state. We find that the associated transition temperature, while quite small in the weakly interacting BCS regime, is experimentally accessible in the strongly interacting unitary regime.

PACS numbers: 05.30.Fk, 03.75.Ss, 67.85.-d, 32.30.Bv

The extraordinary controllability of cold atomic gases has yielded a wide range of interesting phases of matter, including a bosonic Mott insulator and a paired superfluid state of two species of atomic fermions [1, 2]. In the latter setting, experiments have demonstrated control of both the interspecies interactions and the relative density of the two spin states [3, 4], with the latter experimental knob being deleterious to pairing and superfluidity, which favors an equal density of the two species.

Thus, experiments on such imbalanced Fermi gases can probe the stability of superfluidity in a correlated system and therefore may shed light on the tendency towards pairing in related systems, such as electronic superconductors. The phase diagram of imbalanced Fermi gases is quite rich [5, 6], possessing regions of imbalanced superfluidity, phase separation, normal Fermi liquid, and (possibly, though not yet observed) a region of exotic Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) superfluidity [7].

Our present focus is on the strongly imbalanced region, when the polarization \(P = \frac{n_\uparrow - n_\downarrow}{n_\uparrow + n_\downarrow}\) (with \(n_\sigma\) the density of fermion species \(\sigma\)) is close to unity, with a small density of spins-\(\downarrow\) immersed in a spin-\(\uparrow\) Fermi sea. Experiments in this regime [8, 9] have found results consistent with the formation of spin polarons [10], in which a cloud of spins-\(\uparrow\) gather around each spin-\(\downarrow\), leading to a polaron Fermi liquid state [11–13].

The polaron theory of the strongly imbalanced Fermi gas predicts that both the spins-\(\uparrow\) and spins-\(\downarrow\) are Fermi liquids, exhibiting sharp Fermi surfaces at low temperature \(T\). However, general arguments due to Kohn and Luttinger (KL) [14, 15] predict that such Fermi surfaces must be unstable to other ordered states as \(T \to 0\).

A natural question then emerges: What is this ordered state for imbalanced Fermi gases? Since the imposed imbalance (and concomitant Fermi-surface mismatch) precludes \(s\)-wave singlet interspecies pairing, one instead expects triplet (likely \(p\)-wave) intraspecies pairing [14–16] of the spin-\(\uparrow\) and spin-\(\downarrow\) fermions.

In this Rapid Communication we develop a theoretical description of the induced interactions among the majority spin-\(\uparrow\) fermions in the presence of a small density of spins-\(\downarrow\), over a broad range of interaction and polarization values. We find an attractive effective interaction at the spin-\(\uparrow\) Fermi surface, shown in Fig. 1, leading to a \(p\)-wave superfluid transition temperature \(T_c\), computed below [17]. In the extreme weak coupling Bardeen-Cooper-Schrieffer (BCS) limit, where the \(s\)-wave scattering length \(a_s \to 0\), the \(p\)-wave superfluid transition temperature has been computed [16]; unfortunately, it is exceptionally small (in agreement with KL [14]), with \(T_c \propto \exp[-c/(k_F a_s)^2]\), where \(k_F\) is the spin-\(\uparrow\) Fermi wave vector and \(c\) is a constant of order unity. The pairing mechanism is quite simple in this perturbative limit: density fluctuations of one species leads to an attraction between particles of op-

posite spin. For spins-$\uparrow$, this induced interaction is proportional to the spin-$\downarrow$ density-density correlation function (i.e., the Lindhard function). Although a $p$-wave superfluid is predicted in the BCS limit, most experiments occur in the unitary region where the interspecies interactions are strong, $|a_s| \to \infty$, invalidating simple perturbative results. Our analysis of induced interactions in the unitary regime involves extending the ladder approximation (known to describe the polaron Fermi liquid regime discussed above) to include subleading classes of Feynman diagrams. As seen in Fig. 1, the predicted effective interaction in the $p$-wave channel can be quite large near the unitary regime. We find a maximum transition temperature of $k_B T_c \simeq 0.03 \epsilon_F$, which is low but not unreasonable given recently reported temperature scales (e.g., Ref. 18).

Our starting point is the standard one-channel model for two species ($\sigma = \uparrow, \downarrow$) of fermion ($c_{\sigma \mathbf{k}}^\dagger$) interacting via an $s$-wave Feshbach resonance [19]. The Hamiltonian is

$$H = \sum_{\mathbf{k}, \sigma} \xi_{\mathbf{k}\sigma} c_{\mathbf{k}\sigma}^\dagger c_{\mathbf{k}\sigma} + \lambda \sum_{\mathbf{k}, \mathbf{k}', \mathbf{q}} c_{\mathbf{k}+\mathbf{q}\downarrow}^\dagger c_{\mathbf{k}'-\mathbf{q}\uparrow} c_{\mathbf{k}'\downarrow} c_{\mathbf{k}\uparrow},$$

where $\xi_{\mathbf{k}\sigma} = \epsilon_{\mathbf{k}} - \mu_\sigma$, with dispersion $\epsilon_{\mathbf{k}} = k^2/2m$ ($\hbar = 1$) and chemical potential $\mu_\sigma$; $V$ is the system volume (henceforth set to unity), and $\lambda$ is the coupling strength of a short-ranged pseudo-potential, related to the experimentally controllable (via a magnetic field-tuned Feshbach resonance) scattering length $a_s$ via

$$m \frac{4\pi a_s}{\Lambda} = \lambda^{-1} + \sum_{\mathbf{k}} \frac{1}{2\epsilon_{\mathbf{k}}},$$

where $\Lambda$ is an ultraviolet cutoff; below we shall take the limit $\Lambda \to \infty$ while $\lambda \to 0^-$, such that $a_s$ remains fixed.

We are interested in the phases of Eq. (1) in the strongly imbalanced limit $P \to 1$ and proceed (in the spirit of mean-field theory) by assuming the presence of a self-consistently determined pairing amplitude $\Delta_\uparrow(\mathbf{k}, \omega)$ among the spins-$\uparrow$, but not the spins-$\downarrow$. [17]. Under this assumption, the $2 \times 2$ spin-$\uparrow$ Nambu Green’s function, in Fourier-Matsubara space, is

$$\hat{G}_\uparrow(K) = \begin{pmatrix} G_\uparrow(K) & F_\uparrow(K) \\ F_\uparrow(K) & -G_\uparrow(-K) \end{pmatrix},$$

where the four-vector $K = (i\omega_n, \mathbf{k})$. $\hat{G}_\uparrow(K)$ satisfies the Dyson equation [20]

$$\hat{G}_\uparrow^{-1}(K) = \hat{G}_\uparrow^{-1,0}(K) - \hat{\Sigma}_\uparrow(K),$$

with bare Green’s function

$$\hat{G}_\uparrow^{-1,0}(K) = \begin{pmatrix} i\omega_n - \xi_{\mathbf{k}\uparrow} & 0 \\ 0 & i\omega_n + \xi_{\mathbf{k}\downarrow} \end{pmatrix}$$

and self-energy

$$\hat{\Sigma}_\uparrow(K) = \begin{pmatrix} \Sigma_\uparrow(K) & -\Delta_\uparrow(K) \\ -\Delta_\uparrow(K) & -\Sigma_\downarrow(-K) \end{pmatrix}.$$ Using the equation of motion [21], the self-energy can be expressed in terms of the two-particle vertex $\Gamma$, by

$$\hat{\Sigma}_\uparrow(K) = \lambda \sigma_z \sum_{K_1} G_\downarrow(K_1) \left[ \sigma_0 - \sum_{K_2} \hat{G}_\uparrow(K_2) G_\downarrow(K + K_1 - K_2) \Gamma(K_2, K + K_1 - K_2, K_1, K) \right],$$

where $\sigma_0$ is the $2 \times 2$ identity matrix, $\sigma_z$ is a Pauli matrix, and $G_\downarrow(K)$ is the scalar spin-$\downarrow$ Green’s function, which satisfies a similar expression, but with a diagonal self-energy (since we assumed the spins-$\downarrow$ are unpaired). The summation is short for $\sum_K \equiv k_B T \sum_{i\omega_n} \sum_{\mathbf{k}}$.

Although Eq. (3) is in principle exact, to make progress we must make a physically motivated approximation for $\Gamma$, corresponding to certain classes of Feynman diagrams. Previous work has analyzed the phases of imbalanced Fermi gases within the $t$-matrix or ladder approximation [11, 22, 23]. The set of diagrams associated with the ladder approximation also emerges in the large-$N$ approximation [12], in which one generalizes the model to consist of $2N$ species of fermion. Within the present formalism in which $\hat{G}_\uparrow(K)$ has Nambu structure, these contributions arise from including the ladder plus the maximally crossed self-energy diagrams, sketched in Figs. 2(a) and 2(b), respectively. We first analyze Eq. (3) including only these diagrams. Exchanging $\lambda$ for $a_s$ using Eq. (2), and keeping only contributions that are finite in the limit

$$\Lambda \to \infty,$$ we find a diagonal self-energy:

$$\hat{\Sigma}_\uparrow(K) = \sum_Q G_\downarrow(Q) \begin{pmatrix} t(Q + K) & 0 \\ 0 & -t(Q - K) \end{pmatrix},$$

indicating the absence, at this level, of pairing for the spins-$\uparrow$. Here,

$$t(K)^{-1} = \frac{m}{4\pi a_s} + \sum_Q G_\downarrow(K - Q) G_\uparrow(Q) - \sum_q \frac{1}{2\epsilon_q},$$

is the usual scalar $t$-matrix.

Thus, the contributions from Figs. 2(a) and 2(b) yield an unpaired solution for the self-energy, i.e., a Fermi liquid, as found by previous $t$-matrix or large-$N$ theories [11, 12, 22, 23]. Given that the KL arguments imply the eventual instability of this state, we now turn to subleading contributions to the self-energy, shown in Fig. 2(c), that possess ladder and crossed-ladder subdiagrams. Again replacing $\lambda$ for $a_s$ using Eq. (2), we find that these diagrams yield an off-diagonal contribution to
the self-energy, i.e., a pairing amplitude $\Delta^\uparrow(K)$ given by
\[
\Delta^\uparrow(K) = \sum_Q V(K, K') F^\uparrow(K'),
\]
\[
V(K, K') = \sum_P t(P-K)t(P+K')G^\uparrow(P)G^\downarrow(K'+P-K).
\]
Here, $V(K, K')$ is the effective induced interaction among spins-$\uparrow$; the corresponding Feynman diagram is shown in Fig. 1. In principle, the integral equation (6) must be solved self-consistently along with the diagonal self-energy, Eq. (4). However, we shall use some physically motivated approximations to simplify our analysis, focusing on the onset of pairing of the spins-$\uparrow$ at a temperature $T_c$ (above which the system is a Fermi liquid).

We assume the presence of a static momentum-dependent pairing order parameter, $\Delta^\uparrow(K) = \Delta^\uparrow(0)$, and neglect the frequency dependence of $V(K, K')$ [15]. For the diagonal components of the self-energy, we simply assume that the chemical potential is renormalized to the Fermi energy via $\mu_\sigma \to \mu_\sigma - \Sigma_\sigma(k^\uparrow_F, 0) = \epsilon_{F,\sigma}$ (consistent with the Luttinger theorem [24, 25]). Within these approximations and after analytic continuation the effective interaction takes the form
\[
V(k, k') = 2\text{Re} \left[ \sum_q t'(k + q, \xi_{q\downarrow}) t'(q - k', \xi_{q\downarrow}) \right] \times \left[ G^\downarrow_\uparrow(k - k' + q, \xi_{q\downarrow}) n^\uparrow_F(\xi_{q\downarrow}) \right],
\]
where $r/a$ refers to the retarded or advanced quantities and $n^\uparrow_F(\omega)$ is the Fermi distribution function. Equation (6) then simplifies to
\[
\Delta^\uparrow(k) = -\sum_{k'} V(k, k') \frac{\Delta^\uparrow(k')}{2E_{k'}} \tanh \frac{E_{k'}}{2T},
\]
with $E_k = \sqrt{\xi^2_{k\uparrow} + |\Delta^\uparrow(k)|^2}$, the solution of which requires an understanding of the momentum structure of the effective interaction $V(k, k')$ in the vicinity of the spin-$\uparrow$ Fermi surface. The transition temperature $T_c$ for a given angular momentum is found by solving the linearized, in $\Delta^\uparrow(k)$, version of Eq. (9) and projecting onto the relevant channel [19]. Assuming $p$-wave pairing, one needs the $\ell = 1$ projection of the induced interaction, $\gamma^\ell=-1(k, k') = \int_0^\pi d\theta \sin \theta \cos \theta V(k, k')$, where $\theta$ is the angle between $k$ and $k'$. Furthermore, we find via a direct numerical integration of Eq. (8), that $\gamma^1(k, k')$ is only appreciable for $k$ and $k'$ within a range $k_F$ of each other; this defines an effective bandwidth, of the order of $\epsilon_{F\downarrow}$, over which the induced interaction is nonzero.

The strong induced attraction among the spins-$\uparrow$, shown in Figs. 1 and 3a, suggest a robust $p$-wave superfluid at $T \to 0$; to estimate the associated transition temperature $T_c$ we must make further approximations. The remaining momentum integrations in Eq. (9) are sharply peaked at the Fermi surface, yielding the result
\[
k_B T_c \approx \frac{2e^2}{\pi \epsilon_{F\downarrow}} \exp \left[ \frac{1}{\sqrt{N_\uparrow(\epsilon_{F\downarrow})} |t^\uparrow(1)| k_F^\uparrow} \right],
\]
with $\gamma$ the Euler gamma constant. We have also found [26] the same result for the transition temperature (and the same effective interaction, Eq. (7)) via a somewhat different approach by considering the Thouless criterion [27] for $T_c$, determined by the point at which the spin-$\uparrow$ pair-pair fluctuations in the normal state become unbounded. Within such an approach, Eq. (7) is the irreducible vertex in the particle-particle channel of the Bethe-Salpeter equation [28].

In general, (8) has to be determined numerically, but analytic results can be found for certain limiting cases. In the asymptotic BCS limit $a_s \to 0^-$, the $t$-matrix $t/\epsilon^\uparrow(k, \omega) \to 4\pi a_s/m$, and Eq. (8) reduces to the result of Ref. [16] (where, as we have noted, $T_c$ is extremely small). Analytic results can also be obtained in the extremely imbalanced limit, i.e., $k_{F\uparrow}/k_{F\downarrow} \gg 1$. In this limit the $t$-matrices appearing in Eq. (8) also become independent of $k$ and $k'$; $t/\epsilon(k_{F\uparrow} \pm q, \xi_{q\downarrow}) \to \left( \frac{m}{2\pi a_s} \right)^{-1}$. Evaluating the remaining integral gives
\[
k_B T_c \approx \frac{2e^2}{\pi \epsilon_{F\downarrow}} \exp \left[ -\frac{3}{2} \frac{z}{\ln(z)} \left( \frac{\pi}{2k_{F\downarrow} a_s} \right)^2 \right],
\]
with $z = k_{F\uparrow}/k_{F\downarrow}$. This formula correctly captures the vanishing of $T_c$ for $P \to 1$, but doesn’t adequately capture the peaks shown in Fig. 3, which were found by a direct numerical analysis of Eq. (8). These results indicate the presence of pairing at an experimentally accessible temperature in unitary imbalanced gases.

The peak in the induced attraction, and in $T_c$, at large $P$, can be understood by noting that a crucial contribution comes from particle-hole excitations at the spin-$\downarrow$ Fermi surface. However, particle-hole excitations with a transferred momentum larger than $2k_{F\downarrow}$ are energetically suppressed, so that the associated density response...

Within our theory, the spins↑ are also predicted to induce pairing among the spins↓; we find the associated temperature scale to be much lower.

The confirmation of our scenario will require detecting the onset of p-wave pairing at $T_c$ and the properties of the resulting p-wave superfluid below $T_c$. This can be done via standard probes of superfluidity, such as the presence of vortices in a rotating cloud[29]. Following general arguments [30–32], we expect a $p_x + ip_y$ ground state, i.e. $\Delta(k) = \Delta_0 Y_{3,1}(k)$. The anisotropic gapping of the spin↑ Fermi surface should yield a signature in radio-frequency (RF) spectroscopy, which measures the atom transfer rate of one spin species from the interacting system to an unoccupied energy level [33], probing the spectral function. However, we find that the associated peak position in the RF line-shape is at $\omega \simeq \Delta_0 (\Delta_0 / \epsilon_F)$, a very small energy scale given the smallness of $T_c$ computed above. A more promising route, that we leave for future research, is the question of how the onset of pairing impacts the formation of the spin↓ polarons (as reflected in, e.g., the spin↓ RF spectra [8]).

In summary, we have calculated the induced interaction between like atoms in the normal state of an imbalanced two-component Fermi gas. In the absence of any competing instabilities (which certainly occur at smaller $P$, where the regimes of magnetic superfluidity [34], phase separation and, possibly FFLO phase occur), this interaction leads to the formation of a p-wave superfluid in the majority spin species, with a transition temperature that peaks, for $P$ close to unity, at a few percent of the spin↑ Fermi energy.
