Functional Analysis of Lyn Kinase A and B Isoforms Reveals Redundant and Distinct Roles in FceRI-Dependent Mast Cell Activation

Damiana Alvarez-Errico,*† Yumi Yamashita,*†,1 Ryo Suzuki,* Sandra Odom,* Yasuko Furumoto,* Toshiyuki Yamashita,*† and Juan Rivera*

Engagement of FceRI causes its phosphorylation by Lyn kinase. Two alternatively spliced variants, Lyn A and B, are expressed in mast cells, and both isoforms interact with FceRI. Unlike Lyn A, Lyn B lacks a 21-aa region in the N-terminal unique domain. In this study, we investigated the role of Lyn A and B isoforms in mast cell signaling and responses. Lyn B was found to be a poor inducer of mast cell degranulation and was less potent in both inositol 1,4,5-trisphosphate production and calcium responses. Expression of Lyn B alone showed reduced phosphorylation of both phospholipase Cγ-1 and -2 and decreased interaction of phospholipase Cγ-1 with the phosphorylated linker for activation of T cells. Lyn B also showed increased binding of tyrosine-phosphorylated proteins, which included the negative regulatory lipid phosphatase SHIP-1. In contrast, both Lyn A and B caused similar total cellular tyrosine phosphorylation and FceRI phosphorylation and neither Lyn A nor Lyn B alone could completely restore mast cell degranulation or dampen the excessive cytokine production seen in the absence of Lyn. However, expression of both isoforms showed complementation and normalized responses. These findings demonstrate that Lyn B differs from Lyn A in its association with SHIP-1 and in the regulation of calcium responses. However, complementation of both isoforms is required in mast cell activation. The Journal of Immunology, 2010, 184: 5000–5008.

Mast cells are important innate immune cells that can amplify the adaptive immune response (1). They are also known as the central effector cell in IgE-mediated allergic and inflammatory disorders. In an allergic reaction, mast cell activation is initiated through the recognition of an Ag by Ag-specific IgE bound to the α subunit of FceRI, which is expressed on the cell surface. The Src family protein tyrosine kinase Lyn provides the key recognition signal that initiates receptor engagement into intracellular events by transphosphorylating the FceRI β and γ subunits (2). Efficient phosphorylation of the FceRI requires specialized regions of the cell membrane that are enriched in cholesterol and sphingolipids (commonly termed lipid rafts) as both Lyn and FceRI can be concentrated in these domains upon receptor engagement (3). Phosphorylation occurs within the cytoplasmic tails of the β and γ subunits in a domain that encodes the ITAM, which is characterized by a YXXL-X7-YXXL amino acid sequence (4). Once phosphorylated, phospho-ITAMs constitute a novel docking site for the binding and subsequent activation of Src homology 2 (SH2)-domain containing molecules, such as Syk, a tyrosine kinase that is crucial for mast cell activation (5). The activation of Syk results in the phosphorylation of multiple substrates, among which the membrane-localized linker for activation of T cells (LAT) coordinates the assembly of a molecular complex that includes proteins like phospholipase C (PLC)γ. PLCγ catalyzes the hydrolysis of phosphatidylinositol-4,5-bisphosphate to inositol 1,4,5-trisphosphate (IP3) and diacylglycerol. IP3 binds to its receptors on the endoplasmic reticulum, promoting calcium release from the intracellular stores, which, upon emptying, trigger calcium influx from the extracellular environment via store-operated calcium channels like Orai1/CRACM (6, 7). Diacylglycerol binds the C1 domain of a number of proteins (like protein kinase C) promoting their membrane localization and activity. Both the calcium influx and protein kinase C activation are essential for the release of preformed granule-stored allergic mediators and the de novo synthesis of cytokines and eicosanoids from mast cells (8, 9).

As the key initiating kinase, the therapeutic targeting of Lyn is of interest, because intervening at this step should presumably abrogate mast cell activation. However, recent studies suggest that Lyn has both positive and negative regulatory roles (10–12) and, in the context of a particular genetic background, Lyn deficiency could result in either reduced or increased mast cell degranulation and anaphylactic responses (13, 14). In mast cells as well as in other cell types (15), Lyn kinase exists as two isoforms, Lyn A and Lyn B of 56 and 53 kDa, respectively. These isoforms are generated by alternative splicing and differ by a 21-aa insert found in the N-terminal unique domain of Lyn A (Fig. 1A) (16). Prior studies have shown that both Lyn A and Lyn B communoprecipitate with FceRI (17). In addition, both isoforms can be found in lipid rafts (18). In mast cells derived from a mouse model of Smith-Lemli-Opitz Syndrome (an inborn error of cholesterol metabolism leading to loss of cholesterol from lipid rafts) both isoforms of Lyn are lost from lipid rafts, and these mast cells...
showed a hypertensive phenotype (19). Although distinguishing the individual roles of Lyn A and Lyn B (or whether one isoform has a more dominant negative function) is of considerable interest, this was not feasible by means of silencing RNA or genetic deletion strategies, as both isoforms arise from a single gene and differ in a relatively short stretch of nucleotide sequence.

In this study, we investigate the roles of the two Lyn isoforms by expressing each individually or together in mast cells derived from lyn−/− mice. Our results show unique properties as well as redundant roles for the Lyn A and B isoforms. Lyn B was found to dominantly associate with the negative regulatory lipid phosphatase SHIP-1 and was less effective in eliciting calcium responses and mast cell degranulation. However, Lyn B was equivalent to Lyn A in total cellular tyrosine phosphorylation and FceRI phosphorylation. Lyn A showed stronger calcium responses and degranulation than Lyn B and was better in promoting the interaction of PLCγ with phospho-LAT. Importantly, expression of each individual isoform did not fully restore calcium fluxes or degranulation or controlled hypercytokine production, but expression of both isoforms fully normalized these responses. The findings demonstrate differences in the role of these two Lyn kinase isoforms in mast cell signaling and responses. However, they also demonstrate a requirement for both Lyn A and Lyn B in generating normal mast cell responses.

Materials and Methods

Animals

Mice used in this study were wild-type (WT) and lyn−/− (129/Sv, or 129/Sv × C57BL/6 [N8]), which were bred in-house. Animals were maintained and used according to National Institutes of Health guidelines and a National Institute of Arthritis and Musculoskeletal and Skin Diseases-approved animal study proposal.

Abs

Mouse anti-DNP mAb was purified from culture supernatants of the H1-DNP−ε-26.82 hybridoma (20). Mouse mAb to FceRI was previously described (21). Rabbit polyclonal Ab to GST or Lyn were purchased from Invitrogen (Carlsbad, CA) or Santa Cruz Biotechnology (Santa Cruz, CA), respectively. Anti-GST, Rabbit polyclonal Ab to GST or Lyn were purchased from Invitrogen (Carlsbad, CA) or Santa Cruz Biotechnology (Santa Cruz, CA), respectively. Anti-GST, Rabbit polyclonal Ab to GST or Lyn were purchased from Invitrogen (Carlsbad, CA) or Santa Cruz Biotechnology (Santa Cruz, CA), respectively. Anti-GST, Rabbit polyclonal Ab to GST or Lyn were purchased from Invitrogen (Carlsbad, CA) or Santa Cruz Biotechnology (Santa Cruz, CA), respectively. Anti-GST, Rabbit polyclonal Ab to GST or Lyn were purchased from Invitrogen (Carlsbad, CA) or Santa Cruz Biotechnology (Santa Cruz, CA), respectively. Anti-GST, Rabbit polyclonal Ab to GST or Lyn were purchased from Invitrogen (Carlsbad, CA) or Santa Cruz Biotechnology (Santa Cruz, CA), respectively. Anti-GST, Rabbit polyclonal Ab to GST or Lyn were purchased from Invitrogen (Carlsbad, CA) or Santa Cruz Biotechnology (Santa Cruz, CA), respectively. Anti-GST, Rabbit polyclonal Abs

Cell cultures

Total bone marrow from the femurs of lyn−/− and WT 6-wk-old female mice was extracted and used to obtain cultures of bone marrow-derived mast cells (BMMCs). Cells were cultured for 4 wk in the presence of IL-3 and stem cell factor (PeproTech, Rocky Hill, NJ). Cultures were checked periodically for mast cell differentiation and purity by FcεRI and c-Kit expression. Cells were used when cultures achieved ≈95% of the population expressing both markers.

Lentiviral expression constructs

To generate the cDNA construct expressing Lyn A, murine cDNA was amplified using the specific primers Lyna sense: 5′-ATG GGA GCT ATT AAAATCCA AAA AGG AAA G-3′; and Lyn A antisense: 5′-CTA CGG TGG CTG CTATACTG-3′. Lyn B was subsequently generated by deleting the 63 nucleotides encoding the 21-aa insert using the primers Lyn B sense: 5′-AAG ACT CAACCA CCA GAA TTT CAT CTT-3′ and Lyn B antisense: 5′-AAG ACTCAA CCA CCA GAA TTT CAT CTT-3′. Both Lyn A and Lyn B were then cloned into pLenti6/V5-TOPO vector using the Gateway technology kit following manufacturer’s instructions (Invitrogen).

Lentiviral gene transduction

 Supernatants containing virus were harvested after a 48 h transfection of 293FT cells with Lyn A or B constructs (Cell Biolabs, San Diego, CA) as previously described (22). Viral particles were concentrated 25× by centrifugation for 2 h at 20,000 × g. BMMCs (10 × 10^6) were incubated with the viral preparations, medium was changed after 24 h, and selection was started 48 h later with 8 μg/ml blasticidin (Invitrogen). Expression of Lyn A or Lyn B was analyzed by Western blot 2 wk postselection.

Ag stimulation, immunoprecipitation, and Western blotting

For Ag stimulation, BMMCs were sensitized at 37°C for 3 h with 1 μg/ml IgE in RPMI 1640 without cytokines. Cells were washed and stimulated at 37°C with 100 ng/ml Ag (DNP-BSA) or with the indicated concentration in Tyrode’s buffer (135 mM NaCl, 5 mM KCl, 20 mM HEPES, 5.6 mM glucose, 1 mM MgCl2, 1.8 mM CaCl2, 0.05% BSA [pH 7.4]). Stimulation time varied with the type of experiment as indicated. Cell lysates were prepared by incubation of 20 × 10^5 cells in 1 ml BSS buffer containing 0.5% Triton X-100 and 20 mM octyl β-D-glucopyranoside (Sigma-Aldrich, St. Louis, MO) on ice for 15 min. Lysates were clarified by centrifugation for 15 min at maximum speed at 4°C and supernatants collected. Immunoprecipitation was performed with protein A (GE Healthcare, Piscataway, NJ) and the indicated Abs by incubation of cell lysates for 3 h at 4°C in rotation. Proteins were resolved in 10% NuPAGE Bis-Tris gels and transferred to nitrocellulose membranes (Invitrogen). For Western blotting, membranes were blocked for 1 h at room temperature with Odyssey blocking buffer (LI-COR Biosciences, Lincoln, NE) diluted two times in PBS. Membranes were then incubated with the indicated primary Abs, followed by secondary Abs linked to infrared fluorescence dyes. After washings with PBS-0.1% Tween-20 (Sigma-Aldrich), blots were analyzed in the Odyssey Infrared Imaging system (LI-COR).

Measurement of IP3 production and calcium fluxes

Intracellular IP3 was extracted with 20% cold perchloric acid from IgE-sensitized cells (10 × 10^5/sample) challenged with 25 ng/ml Ag. The acidified samples were centrifuged at 2000 × g for 15 min at 4°C, and the supernatants were neutralized with a 1:1 (v/v) mixture of 1.1,2-trichlorotrifluoroethane:trinitroethylene. The concentration of IP3 in each sample was measured with a competitive binding assay (IP3-3H Biotrak Assay System, GE Healthcare).

To measure calcium mobilization, two methods were used. In some experiments, cells were sensitized overnight and loaded with 3 μM Fura 2-AM for 20 min, washed, and aliquoted in 96-well plates (9 × 10^5 cells/well). Cells were then challenged with Ag (25–30 ng/ml), and changes in intracellular calcium were monitored with a microplate fluorescence reader (Opti-Fluor; BMG Labtech, Cary, NC) as previously described (23). In some experiments, single-cell calcium imaging was performed using a Zeiss LSM510 META confocal microscope (Carl Zeiss MicroImaging, Thornwood, NY). The procedure was essentially described (24). Briefly, 5 × 10^4 BMMCs were sensitized with 0.5 μg/ml IgE for 2 h at 37°C in HEPES-Tyrode’s buffer. Cells were loaded with 1.5 μM Fura 4-AM and 5 μM fura Red-AM (Invitrogen), plated on coverslips, and incubated for 30 min at 37°C in the dark. Ag was added after capture of the first 10 images. A total of 75 images at 5-s intervals were captured. The mean of the fluorescent signal of all cells from a field was obtained with the Prism software (GraphPad, San Diego, CA).

β-Hexosaminidase release assays

Mast cell degranulation was measured by the release of the enzyme β-hexosaminidase as described elsewhere (25). Briefly, cells were sensitized for 2 h with 1 μg/ml anti-DNP IgE in medium without growth cytokines. Cells were stimulated for 30 min with varying concentrations of Ag (ranging from 0.1 to 1000 ng/ml) in Tyrode’s buffer followed by supernatant collection. β-Hexosaminidase released into supernatants was measured by incubation with substrate and quantified colorimetrically as described by Blank and Rivera (25).

Cytokine production

For cytokine secretion analysis, 1 × 10^6 BMMCs were incubated with anti-DNP IgE as described above and stimulated with 100 ng/ml DNP for 4 h. Supernatants were collected, and the amounts of IL-6, IL-13, and TNF-α were measured by Millipore Cytokine Multiplex Panel (Millipore, Billerica, MA).

Statistical analysis

Statistical significance of observed differences (p value) was assessed by two-tailed Student t test using the Prism software (GraphPad, San Diego, CA).
Results
Expression of the individual isoforms, Lyn A or Lyn B, does not alter Lyn-dependent phosphorylation of FcεRI or Syk activation

Lyn A and Lyn B isoforms (Fig. 1A) were expressed in BMMCs derived from lyn−/− mice. Stable expression was achieved after 2 wk of blasticidin selection, as described in Materials and Methods, with the protein levels being comparable to those found in WT mast cells (Fig. 1B). Expression of Lyn A or Lyn B alone caused no significant change in mast cell differentiation and FcεRI expression (Fig. 1C). Given the extensive regulatory cross talk among Src protein tyrosine kinases (26), we verified that each individual isoform was active when expressed individually. The kinase activity, after immunoprecipitation of each isoform from cells expressing them individually, was determined in an in vitro kinase assay and compared with the activity in WT cells. As shown in Fig. 1D, each individual isoform was active only in the presence of ATP. Ag stimulation caused only a minimal increase in Lyn activity for both isoforms as measured in vitro, consistent with previously published reports (13), suggesting that large fractions of both Lyn A and B can be readily activated by the presence of ATP in the absence of FcεRI engagement. No kinase activity was found in the immunoprecipitates from Lyn-null mast cells whether transfected to express LacZ or not (Fig. 1D). Thus, expression of the individual Lyn isoforms did not appear to alter their intrinsic kinase activity. To assess the relative activation of Lyn A and B in cells, we measured the phosphorylation of the activation loop Y396 (as recognized by an Ab to Y416 in human Lyn) versus the inhibitory Y507 prior to and after FcεRI stimulation. Fig. 1E shows that, when normalized for the amount of protein expressed, the FcεRI-dependent phosphorylation of Lyn B at Y396 is more prominent than that of Lyn A. Thus, the ratio of Y396/Y507 increased after FcεRI stimulation, whereas the fraction of Lyn A phosphorylated at Y396 showed an initial decrease and a subsequent return to baseline levels. This suggested that Lyn B may be more active in mast cells, but the fraction of Lyn A and Lyn B that is involved in FcεRI-stimulated mast cell responses is unknown, and this would likely determine their relative activities in vivo.

As shown in the control LacZ-transduced lyn−/− BMMCs (Fig. 2A), and also as previously reported (10), the absence of Lyn kinase caused a marked reduction in the total cellular tyrosine

**FIGURE 1.** Lyn A and Lyn B isoforms and their expression in Lyn-null mast cells. A. Schematic representation of Lyn isoforms with the sequence of the 21-aa insert found in Lyn A, but not in Lyn B, indicated. B. Protein expression of Lyn A and Lyn B relative to WT mast cells. C. Analysis of FcεRI expression on cells transduced with lentiviral constructs of Lyn A and Lyn B after blasticidin selection and cell differentiation (5 wk) in IL-3 and stem cell factor. D. Activity of Lyn A and Lyn B as measured by in vitro kinase assays (autophosphorylation). The activity of Lyn A and Lyn B isoforms is not impaired by their individual expression and is regulated by ATP. E. Immunoblot of the phosphorylation status of the activation loop Y396 (using an Ab to human Lyn Y416) and of inhibitory Y507 on Lyn A and Lyn B isoforms, upon FcεRI stimulation. Graph shows the ratio of Y396/Y507 for both isoforms. B–E, A representative experiment is shown.
phosphorylation in resting and FcεRI-stimulated mast cells. This demonstrates that the dectable tyrosine phosphorylation seen in mast cells is highly dependent on Lyn activity. Therefore, it was of interest to determine if the profile of tyrosine phosphorylated proteins might differ considerably in cells individually expressing Lyn A or Lyn B. As shown in Fig. 2A, the total cellular tyrosine phosphorylation did not differ markedly between the two isoforms, and the gross pattern of phosphorylation observed was similar (albeit not identical) to that of WT mast cells. Because Lyn is the kinase responsible for ITAM phosphorylation of β- and γ-chains of FcεRI, we evaluated the relative contribution of the Lyn isoforms to FcεRI tyrosine phosphorylation following the stimulation of this receptor. As shown in Fig. 2B, both Lyn A and Lyn B were equally effective in the phosphorylation of the FcεRI β- and γ-chains, albeit at levels that appeared to be slightly lower than that of WT mast cells. Quantitation of the phosphorylation of the FcεRI β- and γ-chains for all experiments showed that at 3 min poststimulation, the β-chain in WT mast cells had a significantly higher phosphorylation (30%) than in Lyn A- or Lyn B-expressing cells. However, although a trend for increased phosphorylation of the FcεRI γ-chain at 3 min was observed, no significant difference was found for the phosphorylation of the FcεRI γ-chain, and the kinetics of FcεRI phosphorylation were unaltered upon expression of either isoform when compared with WT cells. Thus, Lyn A and Lyn B were equally efficient in the phosphorylation of FcεRI and showed similar ability in inducing total cellular tyrosine phosphorylation.

Given that FcεRI phosphorylation is essential for the activation of Syk kinase (5) and that phosphorylation of mouse Syk on Y346 (which is recognized by an Ab to human Syk Y352, the equivalent site on human Syk) requires Lyn kinase (13), we investigated the effect of Lyn A and Lyn B on phosphorylation of Syk. As shown in Fig. 2C, phosphorylation of Syk at 3 min poststimulation occurred efficiently in cells expressing Lyn A or Lyn B and appeared to be comparable to that seen in WT cells. Varying doses of Ag did not reveal any difference in Syk Y346 phosphorylation between Lyn A- and Lyn B-expressing cells (data not shown). Thus, it is clear that the extent of Syk phosphorylation at Y346 did not differ significantly between Lyn A and Lyn B (Fig. 2C), arguing that both isoforms can promote Lyn-dependent phosphorylation of this site. This was verified, because cells expressing LacZ or Lyn-null cells showed minimal phosphorylation of Y346, consistent with our previous results (13). Thus, both Lyn A and Lyn B are capable of causing Syk phosphorylation at the Y346 site in a manner similar to that of WT cells, consistent with the ability of each isoform to similarly elicit FcεRI phosphorylation.

**Lyn A and Lyn B differ in promoting mast cell degranulation but not cytokine production**

We assayed cells expressing the individual Lyn isoforms for their ability to promote FcεRI-mediated degranulation, as measured by release of granule-localized enzyme β-hexosaminidase. Our past studies (11, 13) demonstrated that Lyn-null mast cells derived from 129/Sv mice or from early crosses to C57BL/6 mice showed hyperresponsive degranulation. In contrast, mast cells from Lyn-null C57BL/6 mice or mice backcrossed extensively (N8) into 129/Sv mice showed hyporesponsive degranulation when compared with WT mice. This difference was due, in part, to the relative levels of Lyn expression, as C57BL/6 mice showed lower levels of Lyn kinase, and hyperdegranulation was restored by overexpression of this kinase (13).

At the onset of these studies, we decided to use lyn−/− BMMCs derived from mice backcrossed extensively (N8) into a C57BL/6 background. These cells showed a marked loss of FcεRI-induced degranulation (Fig. 3A), thus allowing us to determine if Lyn A or Lyn B or both isoforms were needed to promote degranulation. Cells expressing Lyn A or Lyn B showed reduced degranulation response when compared with WT cells (Fig. 3A), albeit the impairment observed in cells expressing Lyn B was more marked. Although Lyn A-expressing cells also showed a reduction in their degranulation response, in some experiments, these cells approached the degranulation response of WT cells. Moreover, Lyn A-expressing cells consistently showed a degranulation response that was considerably higher than Lyn B-expressing cells. The impaired degranulation of Lyn B-expressing cells was not due to a deficiency in granule content or to a developmental defect in the granule fusion apparatus because PMA and calcium ionophore (A23187) elicited a similar and potent degranulation from all cells, regardless of whether they expressed the individual Lyn isoforms or none at all (Fig. 3A).

Previous work (11) demonstrated that the loss of Lyn kinase led to increased cytokine responses in mast cells and that this phenotype was independent of the genetic background of the mice from which the cells were derived (13). Thus, we explored if the different isoforms of Lyn had differing roles in suppressing cytokine responses. In these experiments, we used BMMCs derived from lyn−/− 129/Sv mice because of their potent cytokine responses relative to BMMCs
from lyn−/− C57BL/6 mice. We reasoned that a more potent cytokine response might allow us to more easily ascertain the relative contributions of Lyn A and Lyn B to this response. As shown in Fig. 3B, both Lyn A and Lyn B showed a similar loss in the ability to suppress the hyperproduction of IL-6, IL-13, or TNF, similar to Lyn-null mast cells but markedly differing from WT cells. Neither isoform alone was able to completely restore the negative control of cytokine production to the levels seen in WT mast cells. However, cells expressing Lyn A showed a trend (albeit not significant) toward dampening of the hypercytokine response than those expressing Lyn B. Thus, the findings show that Lyn A more effectively promotes mast cell degranulation and is seemingly better in dampening cytokine responses.

**Lyn B is less effective than Lyn A in evoking Ca2+ responses and optimal IP3 production following FcεRI engagement**

To explore the underlying mechanism for the observed difference between Lyn A and Lyn B in inducing mast cell degranulation, we investigated whether the two isoforms were similarly able to induce intracellular Ca2+ mobilization upon FcεRI stimulation. A rise in the intracellular Ca2+ concentration that is coupled to the influx of Ca2+ from the extracellular medium is essential for the degranulation response (9). As shown in Fig. 4A, both Lyn A and Lyn B showed altered Ca2+ fluxes when compared with WT cells. For both isoforms, the onset and extent of the calcium response was impaired. Lyn B-expressing cells showed the most marked delay in Ca2+ fluxes relative to Lyn A-expressing or WT cells. Nonetheless, in many experiments, the Ca2+ flux of Lyn A-expressing cells was also delayed when compared with WT cells, and the extent of the response appeared to be diminished for both Lyn A- and Lyn B-expressing cells. Relative to the calcium flux of LacZ or Lyn-null mast cells, both Lyn A and B elicited a significant rise in intracellular Ca2+ concentration, and all the analyzed transductants showed a marked increase in intracellular Ca2+ concentrations when stimulated by PMA and the calcium ionophore A23187 (Fig. 4A).

Because the production of IP3 is key for the mobilization of Ca2+ from intracellular stores, which subsequently leads to extracellular Ca2+ influx, the role of Lyn A and Lyn B in IP3 production was also explored. These experiments showed that both Lyn A or Lyn B alone were unable to generate IP3 at levels comparable to that of WT cells, following FcεRI stimulation (Fig. 4B). For Lyn B, there was a marked impairment in the onset and extent of IP3 production relative to WT cells. In contrast, it was found that WT and Lyn A-expressing cells showed a similar early rise in IP3 production, although the extent of the response appeared to be diminished in Lyn A-expressing cells. Thus, the findings demonstrate that Lyn A and Lyn B differ in their ability to induce IP3 production and Ca2+ fluxes, consistent with their observed ability to elicit mast cell degranulation.

**Lyn A and Lyn B differ in their ability to associate with phosphoproteins and LAT**

The difference of Lyn A and Lyn B in promoting IP3 production and Ca2+ fluxes suggested that these isoforms might differ in protein-protein or protein-lipid interactions required for these events. To explore such possibilities, we first assessed whether the two
isoforms could coimmunoprecipitate similar profiles of tyrosine-phosphorylated proteins. Fig. 5A shows that GST-fusion proteins of Lyn A and Lyn B differed in their binding to tyrosine-phosphorylated proteins from FceRI-stimulated cell lysates. Relative to Lyn A, Lyn B showed enhanced binding to tyrosine-phosphorylated proteins, including a prominent band with the molecular mass of LAT. This was further demonstrated by Far Western. Cells were stimulated with pervanadate (to maximize the abundance of phosphorylated proteins), and the total cellular proteins were transferred to nitrocellulose and probed with GST-fusion proteins encoding Lyn A and Lyn B without their catalytic domains. As shown in Fig. 5B, GST-Lyn B bound more effectively than Lyn A to tyrosine-phosphorylated proteins in cell lysates from both nonstimulated and stimulated cells. Collectively, the results show that Lyn B forms stronger or more abundant interactions with tyrosine-phosphorylated proteins than Lyn A. To further explore whether these differences might be seen in cells, we immunoprecipitated Lyn A or Lyn B or both from cells expressing them individually or from WT cells, respectively. Fig. 5C shows that a dominant band identified as LAT was found to coimmunoprecipitate with Lyn B and not Lyn A (albeit weak interactions with Lyn A could be seen in some experiments). LAT was also found to coimmunoprecipitate with Lyn kinase from WT cells and was present in resting cells, although at reduced levels when all experiments were analyzed.

**FIGURE 5.** Lyn B shows increased binding of phosphoproteins, like LAT, when compared with Lyn A. A. GST-fusion proteins (10 µg) encoding Lyn A and Lyn B (without the catalytic domain) were used in pulldown assays from lysates derived from mast cells stimulated (+) or not (−) with Ag. Interacting phosphoproteins were resolved on SDS-PAGE and immunoblotted with an Ab to phosphotyrosine (pY). GST alone was used as a control, and a sample of WCL from stimulated cells was included as a control for testing anti-phosphotyrosine Ab recognition. B. Proteins in the cell lysates (75 µg/lane) from cells stimulated (+) or not (−) with pervanadate (VO₄) were resolved by SDS-PAGE and transferred to nitrocellulose membranes. GST-Lyn A, GST-Lyn B, or GST was used to probe the membranes (Far Western), and binding was detected by use of an Ab to GST. C. Immunoprecipitation of Lyn isoforms from Ag stimulated (+) or resting (−) mast cells expressing Lyn A, Lyn B, and LacZ and from WT cells. Bands corresponding to the Lyn isoforms and LAT were detected with the respective Abs.

Lyn B forms a stable complex with SHIP-1 and decreases the interaction of PLCγ with phosphorylated LAT

Among the many proteins described to interact with Lyn kinase, the lipid phosphatase SHIP-1 is key in controlling the levels of phosphatidylinositol 3,4,5-trisphosphate (PIP₃) following FceRI stimulation (27). SHIP-1 has been shown to interact with PLCγ and modulate its activation (28). Lyn is also required for the phosphorylation of the Tec family kinase BTK (29), which was shown to be required for full phosphorylation of PLCγ and increased activity (29, 30). Because both BTK and PLCγ require PIP₃ for their membrane localization and activation, we explored if the Lyn isoforms showed differences in coimmunoprecipitation of SHIP-1, which might explain differences in promoting calcium responses. Fig. 6A shows that Lyn B binds SHIP-1 more efficiently than Lyn A following FceRI stimulation of mast cells expressing the respective kinases. Tyrosine phosphorylation of SHIP-1 could be seen in the Lyn B coimmunoprecipitates, whereas it was difficult to detect in Lyn A coimmunoprecipitates (data not shown). This interaction was confirmed in pulldown assays in which a GST-Lyn B fusion protein showed the increased presence of SHIP-1 relative to a GST-Lyn A fusion protein (Fig. 6B). Moreover, a GST-Lyn SH2 domain construct showed similar efficiency in its interaction with SHIP-1 (data not shown), demonstrating that this domain is key in promoting this interaction. Because of these findings and the observation that Lyn B associates more prominently with LAT than Lyn A, we explored if LAT was required for the interaction of Lyn B with SHIP-1. Fig. 6B shows that the absence of LAT had only a minor effect on Lyn B–SHIP-1 interactions. A more marked effect was seen for Lyn A, particularly after FceRI stimulation. Moreover, a phosphoprotein of the molecular mass of NTAL/LAB/LAT2 (the Ab recognizing Y191 of LAT also recognizes an equivalent site on LAT2) was also more prominently associated with Lyn B. Regardless, the association of Lyn B with SHIP-1 was not significantly altered by the absence of LAT, showing that this interaction was not LAT-dependent.

Because Lyn B was less effective than Lyn A in inducing Ca²⁺ fluxes, we further explored if Lyn B-expressing cells might be less efficient in causing PLCγ phosphorylation, which would be consistent with the marked reduction in IP₃ production (Fig. 4B). As shown in Fig. 6C, tyrosine phosphorylation of PLCγ and PLCβ2 was markedly diminished (albeit not completely absent) in Lyn B-expressing cells when compared with Lyn A or WT cells. In general, cells expressing Lyn A were also slightly impaired in PLCγ phosphorylation, although this was not apparent in all experiments. Strikingly, the amount of phosphorylated LAT coimmunoprecipitating with PLCγ was reduced in cells expressing Lyn B relative to WT cells (Fig. 6C). Lyn A-expressing cells also showed less binding of phospho-LAT to PLCγ, but this interaction was less affected relative to Lyn B-expressing cells. Thus, the findings demonstrate that Lyn B-expressing cells have an impaired phosphorylation of PLCγ and 2 and a reduced association with phosphorylated LAT relative to Lyn A or WT cells. Because Lyn kinase has been reported to phosphorylate the protein tyrosine phosphatase Src homology region 2 domain-containing phosphatase 1 (SHP-1), we explored the possibility of differential control of this phosphatase by Lyn A and Lyn B, which might explain the differences in the level of LAT and PLCγ phosphorylation. Coimmunoprecipitation experiments revealed no significant association of SHIP-1 with Lyn A or B, under conditions where SHIP-1 was detected, and no difference in the phosphorylation of Y356 on SHIP-1 (the site phosphorylated by Lyn) was observed (data not shown).

This demonstrates that the mechanism underlying the ability of the two Lyn isoforms to evoke a Ca²⁺ response lies in their relative
Complementation of Lyn A and Lyn B activity is required for mast cell activation and responses. A, Mast cells expressing Lyn A or Lyn B individually or jointly were analyzed for Ca²⁺ fluxes and degranulation in response to FcεRI stimulation. B, Cytokine secretion by mast cells expressing the indicated Lyn isoforms and LacZ in comparison with WT or control LacZ-expressing cells. Lyn expression levels were determined from WCLs of each genotype pre- or post-stimulation with Ag. Ab to actin was used to assess similar protein loading. Relative induction (% of total) of intracellular Ca²⁺ fluxes was measured by single-cell analysis. (Materials and Methods). One representative of six experiments is shown. B, Degranulation as measured by the release of hexosaminidase from Ag-stimulated cells (at the indicated concentrations) expressing the individual or both Lyn isoforms in comparison with WT or LacZ-expressing cells. One representative of six experiments is shown. C, Cytokine secretion by mast cells expressing the indicated Lyn isoforms and appropriate controls. IL-6 was measured using an ELISA assay. One representative of three experiments is shown.

Whether expression of both Lyn isoforms in lyn⁻/⁻ BMMCs complemented to normalize some of the responses, such as calcium mobilization, degranulation, and cytokine production, to the levels observed in WT cells. As shown in Fig. 7A, left panel, the ectopic expression of both Lyn A and Lyn B together was similar to the levels of these two isoforms in WT cells, and FcεRI stimulation did not alter this expression. Analysis of the effect on Ca²⁺ responses when both isoforms are restored showed that the isoforms complemented in restoring this response to WT levels (Fig. 7A, right panel). Interestingly, in most experiments, the rise in intracellular Ca²⁺ was still slightly delayed in cells expressing both Lyn A and Lyn B, suggesting that the rate may be determined by factors independent of Lyn or that minor differences in the expression levels of each isoform may affect the rate of this response. As shown in Fig. 7B, the degranulation of cells reconstituted with both Lyn A and Lyn B isoforms was now similar to that of WT cells, and consistently, the response was greater than that of cells expressing Lyn A or Lyn B alone. Thus, the presence of both isoforms caused a full degranulation response in an apparently additive manner (Fig. 7B). Finally, analysis of whether expression of both Lyn A and B would restore control (dampen) on cytokine responses revealed a marked inhibition of IL-6 production (which was similar to the levels of IL-6 production in WT cells) when both isoforms were expressed (Fig. 7C). Collectively, the findings demonstrate that, although Lyn A and Lyn B differ in the efficacy of PLCγ activation and Ca²⁺ fluxes following FcεRI stimulation, both
isoforms complement to achieve a full Ca\(^{2+}\) response, normal degranulation, and to dampen cytokine responses.

**Discussion**

The presence of two Lyn kinase isoforms in hematopoietic cells where this kinase is expressed has long been recognized (16). However, how these two isoforms function and whether both isoforms are required for normal cellular responses has long remained a mystery. In the current study, we explored this unknown by reconstituting Lyn A and Lyn B isoforms individually or together in Lyn-null mast cells. This investigation was not amenable to RNA silencing strategies or gene deletion because the two Lyn isoforms are alternatively spliced products from a single gene and differ only in a 21-aa N-terminal insert found in Lyn A and not in Lyn B (16). Moreover, the requirements for the alternative splicing that generates the Lyn B isoform are not understood, hampering a genetic knock-in approach. How the 21-aa difference in Lyn A and Lyn B can cause the marked changes in functional responses analyzed in this study is not yet completely clear. However, some clues may be derived from their relative ability to coinmunoprecipitate tyrosine-phosphorylated proteins. The 21-aa insert contains a tyrosine (Y32) residue (Fig. 1) that could potentially be phosphorylated. As identified from Prosite database analysis, the amino acid sequence surrounding Y32 has some structural homology with the Y43 site on enolase, which is a protein readily phosphorylated by tyrosine kinases (31). We explored this possibility and found no evidence for phosphorylation of Y32 nor did a Y32F mutant of Lyn A show altered Ca\(^{2+}\) responses or degranulation (data not shown). In contrast, the marked difference of Lyn A and Lyn B isoforms in interacting with phosphoproteins suggests that the 21-aa insert functions to control Lyn A interactions presumably by creating a conformation that limits access to its protein interaction domains (SH2 and/or SH3). How this may occur is undetermined; however, given that GST fusion proteins of Lyn A and Lyn B (which are not tyrosine phosphorylated) maintained their differing ability to bind phosphoproteins, one can conclude that this behavior is not likely to be regulated by tyrosine phosphorylation of the 21-aa insert but most likely results from differences in protein folding/conformation.

Unlike Lyn A, Lyn B poorly induced FcεRI-mediated Ca\(^{2+}\) mobilization and mast cell degranulation. The underlying mechanism for the effect on Ca\(^{2+}\) mobilization and mast cell degranulation was the inability of the Lyn B isoform to effectively promote the phosphorylation of PLC\(\gamma\) and the production of IP\(_3\), crucial steps for these responses (9). Phosphorylated LAT1 was coimmunoprecipitated with PLC\(\gamma\) from Lyn A-expressing cells in greater amounts than from cells expressing Lyn B. This suggests that Lyn B fails to promote and/or impairs this interaction. This finding is consistent with the previous observation that loss of LAT1, or mutation of the PLC\(\gamma\) binding site on LAT1, causes loss of PLC\(\gamma\) phosphorylation, impaired Ca\(^{2+}\) responses, and defective mast cell degranulation (32, 33).

The ability of Lyn B, and not Lyn A, to efficiently associate with SHIP-1 may also be the key factor in the impaired PLC\(\gamma\) activity and reduced Ca\(^{2+}\) response. It has been shown that SHIP-1 coimmunoprecipitates with Lyn kinase from monocytes (34) and from mast cells (35). Moreover, SHIP-1 association with FcεRIIB is a key step for the inhibitory properties of this receptor on FcεRI-mediated Ca\(^{2+}\) responses, following coligation of these receptors (36). Recently, the negative regulatory role for SHIP-1 has been extended to its association with LAT1 in both mast cells as well as in T cells. In T cells, LAT1 organizes an inhibitory complex that includes the adapter Dok-2 and SHIP-1, which serves to dampen the extent of early activation upon TCR engagement (37). In mast cells, LAT1 can also exert an inhibitory role under certain circumstances. Analysis of LAT1 mutants showed the recruitment of SHIP-1 into an FcεRI-induced signaling complex (38). SHIP-1 was found to be recruited to LAT1 in a cooperative manner, in which binding of Grb-2 to tyrosine Y195 potentiates the binding of SHIP-1 to tyrosine Y235. However, our findings suggest that LAT1 is not required for the association of Lyn B with SHIP-1. Deficiency in LAT1 had minimal effect on this interaction, suggesting that the interaction of SHIP-1 with Lyn B is not mediated through this adapter protein. Instead, Lyn B may bring SHIP-1 to LAT1, where it might exert its control by destabilizing PLC\(\gamma\) interaction with the plasma membrane (and thus with LAT1), possibly by reducing the levels of PIP\(_3\), a lipid required for PLC\(\gamma\) translocation to the plasma membrane. It should be noted that other modes of inhibition by SHIP-1 have been described. Dok-1, an adapter that binds SHIP-1, can associate with and negatively regulate FcεRI signaling without the involvement of inhibitory receptors (39, 40). In mast cells, Dok-1 was found to associate with the FcεRI \(\beta\)-chain (40), and its phosphorylation was demonstrated to be Lyn-dependent (41). Thus, it is possible that Lyn B interactions with SHIP-1 might be mediated through the adapter Dok-1. Nonetheless, our analysis of Lyn B immunoprecipitates for the presence of Dok-1 did not reveal detectable levels of this adapter protein (data not shown). Yet, mutation of the noncanonical tyrosine residue that lies in the middle of the FcεRI \(\beta\)-chain caused increased cytokine production in mast cells and led to a modest loss of SHIP-1 phosphorylation, suggesting that this tyrosine residue might interact with this negative regulator (42).

In this study, we also investigated whether the previously described negative regulatory role of Lyn kinase on cytokine production (11, 13) could be ascribed to Lyn A or Lyn B. Although Lyn A consistently showed a moderate dampening of cytokine responses, when compared with Lyn B-expressing cells, this effect was incomplete. That Lyn A showed a greater dampening effect than Lyn B was unexpected, given that the association of SHIP-1 is more prominent with Lyn B and thus one might expect that Lyn B would have a greater dampening effect. Our findings show that expression of both Lyn isoforms is required to restore the control on cytokine production. It is unlikely that the suppression of cytokine responses is related to dampening of Ca\(^{2+}\) mobilization, because expression of both Lyn A and Lyn B increased Ca\(^{2+}\) fluxes following FcεRI stimulation. A plausible explanation could derive from our previous finding that mutation of the FcεRI \(\beta\)-chain ITAM tyrosines, which causes the loss of Lyn association with this receptor, induced increased IκB\(\alpha\) degradation and enhanced nuclear NF-κB activity following FcεRI stimulation (42). It is well established that in mast cells, TNF and IL-6 production are highly dependent on NF-κB activity (43, 44). Thus, both Lyn A and Lyn B may be required to prevent the excessive degradation of IκB\(\alpha\) and thus dampen nuclear NF-κB activity. However, a test of this hypothesis showed the inverse, as FcεRI-stimulated cells expressing the individual Lyn A or Lyn B isoforms were found to have higher amounts of IκB\(\alpha\) protein remaining when compared with cells expressing both isoforms, which had similar content of IκB\(\alpha\) protein to stimulated WT cells (data not shown). Thus, it is unlikely that increased NF-κB activity could account for increased cytokine response of Lyn A- or Lyn B-expressing cells, and how both Lyn kinase isoforms complement to dampen cytokine production remains to be determined.

We now appreciate that the 21-aa N-terminal insert found in Lyn A, and not in Lyn B, determines the efficacy of each isoform in activating PLC\(\gamma\) and generating IP\(_3\), and thus in promoting Ca\(^{2+}\) fluxes. Additionally, key differences were seen in the ability of each isoform to associate with phosphoproteins like LAT and SHIP-1, suggesting that the 21-aa insert governs protein interactions. Most importantly, our findings demonstrate that the Lyn A and Lyn B isoforms have
