Genetic alterations of the transcription factor IKZF1 ("IKAROS") are detected in around 15-30% of cases of BCR-ABL-negative B-cell precursor acute lymphoblastic leukemia. Different types of intragenic deletions have been observed, resulting in a functionally inactivated allele ("loss-of-function") or in "dominant-negative" isoforms. The prognostic impact of these alterations especially in adult acute lymphoblastic leukemia is not well defined. We analyzed 482 well-characterized cases of adult BCR-ABL-negative B-precursor acute lymphoblastic leukemia uniformly treated in the framework of the GMALL studies and detected IKZF1 alterations in 128 cases (27%). In 20%, the IKZF1 alteration was present in a large fraction of leukemic cells ("high deletion load") while in 7% it was detected only in small subclones ("low deletion load"). Some patients showed more than one IKZF1 alteration (8%). Patients exhibiting a loss-of-function isoform with high deletion load had a shorter overall survival (OS at 5 years 28% vs. 59%; \( P<0.0001 \)), also significant in a subgroup analysis of standard risk patients according to GMALL classification (OS at 5 years 37% vs. 68%; \( P=0.0002 \)). Low deletion load or dominant-negative IKZF1 alterations had no prognostic impact. The results thus suggest that there is a clear distinction between loss-of-function and dominant-negative IKZF1 deletions. Affected patients should thus be monitored for minimal residual disease carefully to detect incipient relapses at an early stage and they are potential candidates for alternative or intensified treatment regimes. ( clinicaltrials.gov identifiers: 00199056 and 00198991).

Introduction

IKAROS family transcription factors have been identified as key players in lymphopoiesis.\(^1\) Alterations of IKZF1 in acute lymphoblastic leukemia (ALL) were first described in isolated cases in the early 1990s\(^6,7\) but it took several years to recognize the important role of IKZF1 in ALL development.\(^5,6\) The crucial role of IKZF1 in ALL development has also recently been underlined by the finding that certain non-coding single nucleotide polymorphisms in IKZF1 predispose to B lineage ALL development in later life.\(^10,12\)

The first larger studies on the incidence and role of IKZF1 alterations in ALL were exclusively conducted on pediatric patients and revealed a prevalence of 15-30% of...
**Patients’ samples**

Originally, 507 patients with BCR-ABL-negative B-cell precursor (BCP) ALL were studied (Figure 1). Four were excluded because of irreproducible results, and 21 for missing follow-up data (of these only breakpoint sequences are presented).

Of the remaining 482 patients who were treated within the GMALL protocols 06/99 (n=84; clinicaltrials.gov identifier: 00199056) or 07/03 (n=398; clinicaltrials.gov identifier: 00198991), we analyzed bone marrow (n=330) or peripheral blood with peripheral blasts (n=132; bone marrow or peripheral blood not specified in n=20) obtained at the time of diagnosis between 1999 and 2009 (for blast count see Online Supplementary Tables S2 and S3). Matched samples from the time of relapse were available for 16 out of 482 patients.

**GMALL studies**

Detailed information on treatment has been published previously. The GMALL studies were approved by the ethics committees of participating institutions, and were conducted according to the Declaration of Helsinki.

**Immunophenotyping and molecular genetic analysis**

At the time of diagnosis, immunophenotyping and molecular genetic analysis were performed at the GMALL central laboratory in Berlin, Germany. For all BCP-ALL patients, BCR-ABL status was determined by RT-PCR. Other molecular targets (TCF3-PBX1, ETV6-RUNX1 and MLL fusion genes) were analyzed according to our diagnostic guidelines as outlined previously.

**Genomic PCR for Δ4-7, Δ2-7, Δ4-8, Δ2-8**

For all patients, genomic PCR was performed using HotStarTaq Polymerase Mastermix (QIAGEN) with 40-200 ng DNA and 500 nM of each primer under the following conditions: 15 minutes (min) at 95°C, followed by 35 cycles of 30 seconds (sec) at 94°C, 30 sec at 65°C and 60 sec at 72°C. Primers were located in intron 1 (F2A ACTACAGAGACCTTCACTTCCATTTC, F2B TGATTGGATGTGTGTGTTTCAGGTCGTTG), intron 3 (F4 CCTCCTGCTATTGCACGTCTGG, product 1,229 bp), intron 7 (F7 AGGGACTCTCTAGACAAAATGGCAGGA, product 1,257 bp) or 50 nM (F8 CTTAGAAGCTCTGAGCTCAGAGG, product 1,289 bp). Primers were manufactured by metabion (Munich, Germany) or TIB Molbiol (Berlin, Germany) and HPLC-purified.

![Flowchart of the analysis](image-url)
Reverse transcriptase PCR

RT-PCR was performed with 2 µl cDNA, 500 nM of each primer and the HotStarTaq Polymerase Mastermix (Qiagen) using the following conditions: 15 min at 95°C, followed by 35 cycles of 30 sec at 94°C, 30 sec at 64°C, and 60 sec at 72°C. Primers were located in exons 1 and 8 (RT-PCR ex1/8, primers ex1FA AAAGCGCAGCGACAATCCA and ex8R CTTGTTGAAGCCCTTGGACATCAC) or in exon 1 and exon 4 for detection of Δ2-3 (RT-PCR ex1/4, primers ex1FB CGAGGATGTCCTGCCCCCAA and ex4R GAATGCCCTCACAATCCGACAAAG). Long IKZF1 isoforms were used as internal control. Bands of unexpected sizes were excised from the gel and sequenced.

In cases where RNA was not available for RT-PCR, we used our own and the PCR described by Meyer et al. as genomic screening PCR.

Quantitative PCR for Δ4-7, Δ2-7, Δ4-8

Quantitative PCR was performed in duplicates either for all patients (Δ4-7) or for patients positive in genomic PCR (Δ2-7 and Δ4-8) using a Rotorgene 6000 cycler (Corbett, Concorde, Australia), the Thermo Scientific ABSolute QPCR Mix (Life Technologies, Darmstadt, Germany) with 200-250 ng DNA per PCR and the following conditions: 15 min at 95°C, followed by 55 cycles for 15 sec at 95°C, and 60 sec at 72°C.

As DNA standard, we used the cell-line BV-173 for Δ4-7 (DSMZ, Braunschweig, Germany) or patient DNA (#100 for Δ2-7, #101 for Δ4-8). A PCR for the HCK gene served as internal control as described earlier. Oligonucleotides are given in Online Supplementary Table S4. Deletions were considered to be present in a large fraction of leukemic cells (“high deletion load”, “highdel”) when the relative PCR signal was >10^3, otherwise they were considered having a "low deletion load" ("lowdel"). The cut-off value was chosen a priori since this threshold appeared to separate samples with a high and low mutation load (Online Supplementary Figure S1). We used MLPA (SALSA MLPA P335 ALL-IKZF1 kit, MRC Holland, Amsterdam, the Netherlands) to correlate the cut-off values of our quantitative PCRs with MLPA deletion values. We investigated a subset of patients with qPCR signals that we expected to yield a MLPA reduction of 0.3 or more (i.e. qPCR signal of 0.6 or higher). The chosen thresholds distinguishing highdel and lowdel corresponded to 5% deleted alleles in case of Δ2-7

Figure 2. Detection of IKZF1 deletions by RT-PCR and PCR screening. (A-C) RT-PCR with primers in exon 1/8. Increased Ik6 expression in lanes 4-6 and increased Ik10 expression in lanes 6-8. Reduced full length isoform expression in lanes 1 and 7 is attributed to an additional deletion Δ2-3 in these 2 patients detected by another RT-PCR (see Online Supplementary Figure S2). (B) PCR Δ4-7. In lanes 1-3, Δ4-7 is present with a low deletion load; in lanes 4-6, the deletion is present with a high deletion load. Corresponding qPCR results are given below. Control band of 1257 bp. (C) PCR Δ2-7 with low deletion load in lanes 3-4 and high deletion load in lanes 6-8. Control band of 1257 bp. (D) Structure of the IKZF1 transcript isoforms Ik1 (full-length), Ik6 (loss of exons 4-7) and Ik10 (loss of exons 2-7). (E and F) PCR Δ4-8 and PCR Δ2-8 of the identical patients in lanes 10-17. Control band of 1229 bp. (E) PCR Δ4-8. See double bands in lanes 10 and 11. (F) PCR Δ2-8. See variant breakpoint in lane 17.
and Δ4-7, and 10% in Δ4-8, but the latter could equally well have been placed at 5%, since there were no samples between 5% and 10%.

In cases negative for Δ4-7 by conventional PCR but positive by qPCR, qPCR measurements were repeated and were considered positive when at least 3 out of 4 measurements were positive.

Gel densitometry

When no quantification by qPCR was possible (n=41), we assessed the relative amount of cells with IKZF1 deletions (high vs. low deletion load) by gel band densitometry using the AlphaEaseFC v.4.0 software (Alpha Innotech, San Leandro, CA, USA). In deletions Δ2 (n=1) and Δ2-3 (n=17, missing values n=2), we compared deleted isoforms to full-length isoforms on RT-PCR images with a cut-off value of 0.60. In deletions Δ2-7 (n=5), Δ4-7 (n=5) and Δ5-7 (n=1) we compared deleted with long bands on RT-PCR images using a cut-off value of 1.20. In Δ2-8 (n=10) and Δ4-8 (n=2) we calculated the ratio of short PCR products to the long PCR control band with a cut-off value of 1.20.

Supplementary methods

Nucleic acid preparation, identification of rare genomic breakpoints (primer sequences specified in Online Supplementary Table S5),31 DNA sequencing, bioinformatic analysis,34 and statistical analysis are all described in the Online Supplementary Methods.

Results

Patients’ characteristics

All 482 patients were aged between 16 and 65 years at diagnosis (Online Supplementary Table S6). The median age was 32 years [interquartile range (IQR) 22-47]. Two hundred and eighty-five patients (59%) were male. The distribution of immunophenotypes was 111 pre-B ALL (cyIg+; 23%), 314 common ALL (cyIg-,CD10+; 65%) and 57 pro-B ALL (CD10-; 12%). Two hundred and fourteen patients (44%) were considered high risk, the remaining standard risk. All patients were BCR-ABL-negative and a MLL rearrangement was detected in 44 patients (89 MLL-AF4, 4 MLL-ENL, 1 MLL-AF9), a TCF3-PBX1 fusion in 30, and an ETV6-RUNX1 fusion in 3 cases.

Frequency of IKZF1 deletions

Two RT-PCRs were used to detect short IKZF1 isoforms (Figure 2A and Online Supplementary Figure S2A-C) and four separate PCRs to detect the Δ2-7, Δ2-8, Δ4-7 and Δ4-8 isoforms (Figure 2B-F). Deletions were then quantified using quantitative PCR or gel densitometry. Dominant-negative deletions (Δ4-7, Δ5-7) were compared to loss-of-function deletions (Δ2, Δ2-3, Δ2-7, Δ2-8, Δ4-8).

Overall, 128 of 482 (27%) patients carried an IKZF1

![Figure 3. Prevalence of IKZF1 deletions at the time of diagnosis.](image-url)
deletion (Figure 3A). Among these patients, we detected 175 different \( \text{IKZF1} \) deletions. While 91 (19%) patients expressed only one deletion, in 37 (8%) patients more than one \( \text{IKZF1} \) deletion was detected: 2 (n=28), 3 (n=8) or 4 (n=1) deletions (Online Supplementary Table S7; for an example, see lanes 3, 4 and 6 in Figure 2).

Among the 175 \( \text{IKZF1} \) deletions, \( \Delta 4-7 \) was the most frequent (n=71). \( \Delta 2-7 \) was found in 47, \( \Delta 4-8 \) in 26, \( \Delta 2-3 \) in 19 and \( \Delta 2-8 \) in 10 patients. Rare deletions were \( \Delta 5-7 \) (n=1) and \( \Delta 2 \) (n=1). In summary, 56 patients (12%) carried only loss-of-function deletions, 50 (10%) had only dominant-negative deletions while 22 patients exhibited both types of deletions (5%).

We then quantified the amount of cells with \( \text{IKZF1} \) deletions, as a variable deletion load was apparent from gel images (Figure 2B and C). We avoided the simple terminology "clonal" and "subclonal" since we did not prove clonality in a strict sense and did not investigate clonal relationships. Instead, we adopted the terms "high deletion load" (highdel) and "low deletion load" (lowdel) for clonality in a strict sense and did not investigate clonal terminology "clonal" and "subclonal" since we did not prove deletions, as a variable deletion load was apparent from gel images (Figure 2).

qPCR screening revealed 50 additional cases positive for \( \Delta 4-7 \) with a low deletion load not detectable by our conventional PCR. In 41 of these cases, the lowdel \( \Delta 4-7 \) was the only \( \text{IKZF1} \) deletion. Among these patients, we detected a high deletion load. At least one highdel \( \text{IKZF1} \) deletion could be found in 98 of 482 (20%) patients (Figure 3B). Among these, 50 had a highdel loss-of-function deletion only, 44 patients had a highdel dominant-negative deletion only, and there was a group of 4 patients expressing both deletions with a high deletion load level.

Four hundred and twenty-eight (89%) patients reached a complete remission, 31 patients (6%) died during induction, and 23 patients (5%) had a treatment failure after a complete remission, 31 patients (6%) died during induction.

We first calculated the effect of any \( \text{IKZF1} \) deletion. There was a trend towards a lower frequency of \( \text{IKZF1} \) deletions not associated with patients’ age, gender, WBC or GMALL risk group, neither for all deletions (Online Supplementary Table S8), nor for different types of deletion (Online Supplementary Table S9).

| Type of \( \text{IKZF1} \) deletion | Patient group | Cases pos/neg | Overall survival | \( P \) |
|----------------------------------|---------------|---------------|-----------------|-----|
| Any mutation                     | all patients  | 128/354       | 0.46±0.05       | ns  (0.06) |
| Loss-of-function                 | all patients  | 78/404        | 0.37±0.06       | 0.0012 |
| Dominant-negative                | all patients  | 72/410        | 0.54±0.06       | 0.0012 |
| High deletion load loss-of-function | all patients | 54/427        | 0.28±0.06       | <0.0001 |
|                                  | SR           | 24/243        | 0.37±0.10       | 0.0002 |
|                                  | HR           | 30/184        | 0.26±0.08       | ns  (0.06) |

\( P \): positive, \( n \): negative, \( \text{SR} \): standard risk according to the German Multicenter Acute Lymphoblastic Leukemia (GMALL) studies, \( \text{HR} \): high risk according to GMALL.
Oligoclonality is more common in loss-of-function deletions

Some patients showed more than one IKZF1 deletion (e.g. Δ2-7 and Δ4-7). Forty out of 175 deletions (23%) showed more than one chromosomal breakpoint resulting in the same type of RNA transcript. This oligoclonality may arise from multiple alterations in a single hyperdiploid clone or from alterations in different clones. This was evident either by gel electrophoresis (9 patients; see lanes 9-10 in Figure 2E and F) or by multiple sequences in chromatograms (2 breakpoints in 5 patients, Figure 5A; more than two breakpoints in 26 patients, Figure 5B). This kind of oligoclonal pattern occurred more often in loss-of-function deletions (31 of 103 deletions, 30%) compared with dominant-negative (9 of 72, 13%; P = 0.0064).

Breakpoint sequences

Sequencing of 193 breakpoints revealed four clusters (Figure 5C; for all breakpoints see Online Supplementary Table S10). In intron 1, 66 of 83 were located within 30bp. In intron 3, 106 of 108 proximal breakpoints were located within 40bp. All 132 distal breakpoints in intron 7 clustered within 43bp. Thirty-six of 42 breakpoints in the 3'UTR region were located in a 27bp region, and an additional 5 breakpoints clustered around 500bp proximally.

The remaining 17 breakpoints in intron 1 were more diverse, covering a region of 7kb. Distal (3') breakpoints in intron 3 (Δ2-3) were scattered all over the 40kb intron. In 183 of 193 (95%) molecularly characterized breakpoints, putative cryptic recombination signal sequences, either with 23bp or 12bp spacer, were identified at both breakpoint sites (5' and 3'). This was the case for the four major breakpoint clusters (Figure 5 and Online Supplementary Table S11) but also true for the majority of the atypical breakpoints in intron 1 and 3. In 10 of 25 atypical breakpoints, only one cRSS could be identified (8 only on the 3' site, 2 only on the 5' site) (Online Supplementary Table S11). There was no evidence of somatic hypermutation near the break sites.

Detection of deletions by RT-PCR

In 13 of 17 patients positive for Δ2-3 in RT-PCR ex1/4, a genomic breakpoint could be identified by eyer et al.'s PCR (Online Supplementary Figure S2A). In the remaining 4 patients, breakpoints were identified by a newly developed PCR (Online Supplementary Figure S2B). We also identified Δ2 once by RT-PCR ex1/4 and confirmed the genomic deletion. One patient expressed isoform Δ2-4 in RT-PCR ex1/3 but we could only find a deletion Δ2-3 on the genomic level and no deletion Δ2-4 or Δ4.

RT-PCR revealed 3 patients positive for Ik10 (lacking exons 2-7) but negative for Δ2-7 by genomic PCR due to a more proximal 5' breakpoint (Online Supplementary Figure S4A). In all 70 cases of RT-PCR positive for Ik6 (lacking exons 4-7) and negative for Ik6Δ (lacking exons 4-7 but with an additional 60 bp cryptic exon 3b), genomic PCR...
was positive for deletion Δ4-7. In one patient with Ik6 and Ik6Δ we found two deletions Δ4-7, one with common breakpoints, one with a 5' breakpoint distal to the 60bp insert (Online Supplementary Figure S4B). The second patient with Ik6/Ik6Δ showed only a deletion Δ5-7 that was supposedly the reason for overexpression of Ik6 and Ik6Δ (Online Supplementary Figure S4C).

Comparison between diagnosis and relapse

DNA at the time of relapse was available from 16 patients carrying 20 IKZF1 deletions. Four in 7 (57%) Δ4-7 and 9 in 13 (69%) loss-of-function deletions were conserved (P=0.65) (Online Supplementary Table S12). Eleven in 15 (73%) highdel and 1 in 4 lowdel deletions were conserved (P=0.12; 1 deletion not quantified). All genomic breakpoints were identical at the time of diagnosis and relapse. No newly acquired deletion Δ2-7, Δ2-7, Δ4-7 or Δ4-8 could be detected in relapse samples. We also investigated 5 relapse samples from patients who had shown a lowdel Δ4-7 IKZF1 deletion at diagnosis, detectable only by quantitative PCR. None of these cases evolved into a major clone, i.e. with high deletion load at relapse.

Discussion

IKZF1 alterations have been recognized as recurrent aberrations in B-precursor ALL but their prognostic impact in adult ALL is still not well defined. Two major studies involving more than 200 patients have focused on the prognostic impact in BCR-ABL-negative adult BCP ALL. Moorman et al.21 investigated 304 patients and found IKZF1 deleted patients (29%) to have a lower OS, but this was only seen in a univariate analysis. The authors stated cautiously that “there was evidence to suggest that the poor outcome was not linked to the expression of the IK6

Figure 5. Distribution of IKZF1 breakpoints and clonality of deletions. (A) Chromatogram of patient #189 showing two distinguishable clones (sequenced sense and antisense reverse complement). (B) Chromatogram of patient #395 showing oligoclonality at the breakpoint junction in both sequencing directions. (C) Distribution of breakpoints in the IKZF1 gene locus. Proximal breakpoints are shown in black, distal breakpoints in blue. There are four major breakpoint clusters within intron 1, 3, 7 and 3'UTR of IKZF1.
isofrom but rather to other types of IKZF1 deletions. Beldjord et al. investigated 216 younger adults and observed a significantly higher cumulative incidence of relapse in patients with focal IKZF1 alterations (25%) but not with whole gene deletion. No statistically significant difference between patients with different focal alterations was observed.

Our present study included 482 homogenously treated patients and revealed IKZF1 alterations in 128 cases. The incidence of focal deletions (27%) was comparable to both studies mentioned above. Our study is the first to systematically address the issue of IKZF1 mutation load and its implications for prognosis on a larger scale. This is of diagnostic interest if IKZF1 alterations are to be used as molecular markers for risk stratification and/or for detecting minimal residual disease. Ninety-eight patients revealed a high deletion load IKZF1 aberration while 29 patients showed low deletion load IKZF1 alterations only (n=1 not quantified). Regarding clinical implications, only high deletion load loss-of-function IKZF1 alterations were of prognostic relevance and conferred an adverse prognosis while low deletion load IKZF1 alterations or dominant-negative IKZF1 alterations did not have a prognostic effect.

In animal studies, double IKZF1 knock-out mice show a total absence of B cells. Mice with only IKZF1 deletions did not develop BCP ALL, but haploinsufficiency of IKZF1 in BCR-ABL transgenic mice significantly accelerated the development of BCP ALL. Current evidence suggests that IKZF1 alterations alone are not sufficient to cause leukemia in humans but are an important co-factor or secondary event in the development and acceleration of ALL disease.

It may seem unexpected that the loss of one IKZF1 allele without apparent functional alteration of the other allele should have such a significant prognostic effect. However, this is supported by the above mentioned mouse model of Virely et al. The observation that loss-of-function IKZF1 deletions frequently occur in a small fraction of cells, but only seem to have an impact on prognosis if they are found in a large fraction, requires some explanation. A hypothetical explanation is the assumption that RAG-mediated IKZF1 deletions occur sporadically during all stages of B-cell maturation because of the ongoing process of VDJ recombination. However, only those IKZF1 alterations occurring at a very early maturation stage are thought to result in a cell phenotype with the full capacity of self-renewal, i.e. a "leukemia stem cell phenotype". IKZF1 alterations occurring at later stages of B-cell maturation should result in low deletion load aberrations.

The extremely narrow clustering of breakpoints in regions comprising only a few nucleotides strongly argues in favor of a specific mechanism. The analysis of the breakpoint junctions revealed four breakpoint clusters in the vicinity of recombination signal sequences suggestive of a break mechanism involving the immunoglobulin VDJ recombination enzyme complex. RAG1 and RAG2 and other genes involved in VDJ rearrangement are not expressed at a very early stage of differentiation but only after lymphoid commitment, which would be in line with the assumption that IKZF1 deletions are a later event in the path towards the malignant phenotype. The fact that cRSS could not be identified in 10 out of 193 breakpoints may be explained by limitations of the RSSite software, since some of these breaks occurred in near vicinity, suggesting a specific mechanism.

The PCR method used in this study has the advantage that it can also detect IKZF1 alterations in a small fraction of leukemic cells, which is not possible when using MLPA. Since we analyzed the final IKZF1 cDNA transcript, we were in principle also able to detect deletions or aberrant splice isoforms arising from alterations involving only a few nucleotides that would escape detection by MLPA. However, MLPA has the advantage of also detecting whole gene deletions that are not detectable with our PCR-based approach. As long as there are no reliable PCR-based detection methods for the former, and given the fact that low deletion load alterations are prognostically irrelevant, we consider MLPA to be a suitable detection method.

To summarize, we detected partial IKZF1 gene deletions in approximately 27% of cases of adult BCR-ABL-negative adult ALL. Only high deletion load loss-of-function IKZF1 alterations, but not dominant-negative IKZF1 alterations, had negative prognostic implications and should thus be monitored closely, while those that were found in a small fraction of cells did not influence prognosis. We report extensive molecular data on these alterations which should help to establish suitable diagnostic methods for their detection and which shed additional light on the molecular pathogenesis.

Acknowledgments
The authors are grateful for the excellent technical work of D. Giegler, R. Lippoldt and colleagues and the members of the MPI sequencing team in Cologne. They thank all involved patients and physicians for participating in the GMALL studies. TB was supported by DFG grant BU 2453/1-1.
