TOC/ABSTRACT GRAPHIC

**ABSTRACT** Sulfoximines are of considerable interest for incorporation into medicinal compounds. A convenient synthesis of N-protected sulfoximines is achieved, under mild conditions, by rhodium-catalyzed transfer of carbamates to sulfoxides. The first examples of 4-membered thietane-oximines are prepared. Sulfoximines bearing Boc and Cbz groups are stable to further cross coupling reactions, and readily deprotected. This method may facilitate the preparation of NH-sulfoximines providing improved
(global) deprotection strategies, which is illustrated in the synthesis of methionine sulfoxide (MSO).

INTRODUCTION

Sulfoximine derivatives have received the attention of synthetic chemists over several decades.¹ Many applications have concerned their use as ligands, and auxiliaries,² ³ and recently they have been employed as directing groups for catalytic ortho-C–H functionalization.⁴ Since the identification of methionine sulfoximine (MSO),⁵ the first sulfoximine discovered, there has also been significant interest in their effects on biological systems (Figure 1).⁶

![Figure 1. Sulfoximines in biologically active compounds](image)

MSO and buthionine sulfoximine (BSO) are useful tools for the inhibition of the biosynthesis of glutathione (GSH).⁷ However, the more general use of the sulfoximine group in medicinal chemistry follows the development of BAY 1000394, a pan-CDK inhibitor that is currently in phase 1 clinical trials for cancer in patients with advanced solid tumors.⁸ In this case the sulfoximine conferred improved solubility versus a sulfonamide predecessor. Sulfoximines are now increasingly intriguing options for inclusion in drug discovery programs.⁹ Much of this interest is due to their attractive structural features to improve physicochemical properties. These polar and stable functional groups offer hydrogen bond acceptors and donors, aid solubility, introduce asymmetry at the sulfur atom and provide additional points of substitution through the nitrogen atom.

Advances in their medicinal chemistry usage have necessarily followed the development of improved synthetic routes.¹⁰ Early approaches to sulfoximine synthesis required forcing and hazardous conditions
such as sodium azide in concentrated acid.\textsuperscript{11} Recently, safer and more tolerant nitrogen transfer methods have been reported, both through imidation of sulfoxides,\textsuperscript{12,14-18} and the reverse, imidation of sulfides to form sulfilimines followed by oxidation.\textsuperscript{13} In particular there has been considerable effort aimed at the development of methods for transition metal-catalyzed $N$-transfer to sulfoxides via metal nitrenoid species (Scheme 1).

The transfer of sulfonamide groups using activated nitrogen species (e.g. PhI=NN=Ns) has been achieved with Cu,\textsuperscript{14} Rh,\textsuperscript{15} Ag\textsuperscript{16} and Fe\textsuperscript{17} catalysis (Scheme 1a). While Ts groups are challenging to deprotect, the Ns group can be removed by treatment with thiophenol and cesium carbonate.\textsuperscript{16} Bolm demonstrated that trifluoroacetamide could be introduced, using Rh$_2$(OAc)$_4$ and PhI(OAc)$_2$ to generate the active $N$-species in situ (Scheme 1b).\textsuperscript{15} Treatment with K$_2$CO$_3$/MeOH effected deprotection. The transfer of nitrenes derived from simple amides has been unsuccessful under hypervalent iodine mediated conditions. Therefore, Bolm developed the use of 1,4,2-dioxazol-5-ones to transfer a range of amides requiring photochemical activation and a Ru catalyst (Scheme 1c).\textsuperscript{18} Richards reported a Rh-catalyzed method for the direct preparation of $NH$-sulfoximines using $O$-(2,4-dinitrophenyl)-hydroxyl-amine with Rh$_2$(esp)$_2$ as the catalyst.\textsuperscript{19} Methods for $N$-functionalization of $NH$-sulfoximines have also undergone significant recent development, including methods for $N$-arylation,\textsuperscript{20} acylation,\textsuperscript{21} alkynylation,\textsuperscript{22} and alkylation.\textsuperscript{23}
We required protected sulfoximines that would be stable to nucleophiles and bases used in further synthetic transformations prior to revealing the $NH$-sulfoximine. We identified sulfoximine carbamates as most suitable. Bolm has previously demonstrated that $N$-Boc sulfoximines were stable to Pd-catalyzed cross-coupling at other positions in the molecule. In that study, the Boc group was introduced by the reaction of preformed $NH$-sulfoximines with (Boc)$_2$O. Similarly, in the reported synthesis of BAY1000394, an $NH$-sulfoximine intermediate was protected as an ethyl carbamate during reduction of a nitro group, before later deprotection. To date there is no direct and general method for the preparation of carbamate-protected sulfoximines from sulfoxides. The only previous investigation into the preparation of Boc sulfoximines from sulfoxides by Bach used Boc-azide (Scheme 1d). However, the potentially explosive nature of BocN$_3$ has limited the application of this method.

We considered that direct methods for the syntheses of carbamate sulfoximines would be valuable to provide protected sulfoximines that may be revealed selectively or when synthetically most advantageous. In addition they may provide interesting groups in their own right in medicinal chemistry, or as ligands or auxiliaries. Here we report the direct preparation of sulfoximine carbamates including...
Boc and Cbz as well as methyl, ethyl, phenyl and allyl derivatives, by the Rh-catalyzed nitrogen transfer of carbamates (Scheme 1e). We demonstrate the stability of the Boc and Cbz groups to further manipulations of sulfoximines, in the form of cross-coupling reactions, as well as their removal. We also report the first preparation of thietane-oximines, and a preparation of MSO via the Boc-sulfoximine.

RESULTS AND DISCUSSION

There are few examples of intermolecular transfer of nitrenoids derived from simple carbamates in any transformation.\(^{27}\) Inspired by the Bolm method,\(^{15}\) our study began investigating conditions employing BocNH\(_2\) and PhI(OAc)\(_2\), intending to generate an activated BocN=IPh species in situ to transfer to a sulfoxide. Using rhodium catalysis and magnesium oxide as base, we were delighted to observe the direct formation of the N-Boc sulfoximine 2a from sulfoxide 1a in good yield (Table 1, entry 1).\(^{25}\)

From this starting point, we intended to reduce the reaction times and minimize the excess of reagents required, due to the excess carbamate causing difficulties in purification. Initially reducing the equivalents of carbamate and PhI(OAc)\(_2\) led to a reduction of yield (entries 2-3). Warming the reaction gave a slight improvement (entry 4). The crucial variables were the interplay of time and temperature. With the larger excess of reagents, the reaction time could be significantly reduced, and warming to 40 °C gave an 87% yield (entries 5 and 6). At 40 °C with an 8 h reaction time, complete conversion was observed (entry 7). Under these optimized conditions, a 98% yield of the desired N-Boc sulfoximine 2a was obtained (0.6 mmol scale, Scheme 2). No reaction occurred in the absence of the Rh-catalyst (entry 8). At a 4 mmol scale 94% conversion and 80% isolated yield was obtained with 8 h reaction time. The N-transfer was stereospecific as performing the reaction on (S)-tolyl methyl sulfoxide (er 97:3) led to complete retention of the er in N-Boc-sulfoximine 2a.\(^{28,29}\) Importantly, the reaction conditions are not sensitive to air and water; all reactions were performed under air without using anhydrous dichloromethane.

Next, the scope of the reaction was examined using BocNH\(_2\) as the nitrogen source (Scheme 2). Variation of the electronics of the aromatic component by using 4-chlorophenylsulfoxide 2b also gave a good yield. With the isopropyl substituted sulfoximine 2c the yield was somewhat reduced, as might be expected from the increased steric hindrance. Other substituted alkyl derivatives (2d and 2e) gave excellent yields, as did diphenyl sulfoxide and phenyl vinyl sulfoxide to afford respectively sulfoximines 2f and 2g. Dibenzyl sulfoxide and tetrahydrothiophene 1-oxide were also successful providing 2h and 2i.\(^{30}\) Methyl carbamate and ethyl carbamate were equally reactive, under the same conditions, generating the corresponding sulfoximines 3 and 4 in high yield (Scheme 2).
Attempts to directly translate the optimal reaction conditions used above to form Cbz protected sulfoximines gave a significant reduction of the yield (37%). A similar reduction in yield was observed with phenyl carbamate; presumably an unfavorable coordination of the π-system to the catalyst slowing the reaction. The reaction parameters were examined again, and ultimately, increasing the concentration of the reaction from 0.1 M to 0.3 M in sulfoxide gave improved yields (60% yield for 5a, Scheme 3). Under these conditions, for both benzyl and phenyl carbamates, good yields of the corresponding sulfoximines 5b,g, and 6a,h, were achieved, though notably lower than the alkyl carbamates. The use of allyl carbamate was also successful under the more concentrated reaction conditions, forming sulfoximines 7a and 7b, but side reactions reduced the yield (Scheme 3). Dimethylurea, methyl 4-aminobenzoate and 2-aminopyridine were also examined as possible reagents but each returned only
Next, as part of our interests in the synthesis of novel 4-membered ring heterocycles, we examined the preparation of unusual 4-membered cyclic sulfoximines. Thietane oxide 8 was prepared by oxidation of thietane with hydrogen peroxide, as previously reported. This substrate proved to be reactive and was successful for all carbamates under the conditions reported above. The alkyl carbamates gave the thietane-oximines 9-11 in excellent yields, where as the benzyl, phenyl and allyl gave lower yields (12-14), indicating the relative reactivity of the nitrogen sources. Further studies with these compounds will be reported in due course.

**Scheme 4: Thietane-oximines**

The stability and utility of the orthogonally protected N-Cbz- and N-Boc-chlorophenyl sulfoximines
(2b and 5b) was demonstrated in Suzuki cross-couplings with aryl boronic acids, and Fe-catalyzed cross-couplings of alkyl Grignard reagents (Scheme 5). The couplings proceeded in good yields in each case, leading to further elaborated sulfoximine derivatives (15-18).

**Scheme 5: Cross coupling of chloro-sulfoximine 2b and 5b**

The Boc- and Cbz-sulfoximines 2a and 5a were also readily deprotected using standard conditions to generate the free NH-sulfoximines in good to excellent yields, highlighting the convenience of these N-carbamate sulfoximines. The parent thietaneoximine 20 was prepared by deprotection of N-Boc derivative 9 using TFA.

**Scheme 6. Boc and Cbz deprotection of sulfoximines**

To illustrate the potential for synthetic advantage of introducing a Boc group, we prepared MSO with a final global deprotection step, a target recently examined by Bolm to assess alternative protecting group strategies. Our approach involved the direct formation of the N-Boc sulfoximine 22, as a 1:1 mixture of diastereoisomers, from protected methionine sulfoxide 21. Fully protected 22 could be readily purified. The sulfoximine Boc group was then removed, along with the other Boc group and tert-butyl ester, under acidic conditions to afford MSO in 54% yield over the two steps following purification by ion exchange chromatography (Scheme 7).
Conclusion. We have developed a general and convenient procedure for the preparation of sulfoximine carbamates. Under rhodium catalysis, BocNH$_2$ and CbzNH$_2$, as well as methyl, ethyl, phenyl and allyl carbamates are transferred stereospecifically to a range sulfoxides in high yields. We expect these sulfoximine carbamates to provide interesting variations to chiral auxiliaries or ligands, as well as new motifs for medicinal chemistry. This approach may facilitate synthetic planning by allowing flexible removal of protecting groups to access NH sulfoximines.

EXPERIMENTAL SECTION

General Considerations: All reactions were carried out under atmospheric conditions using solvents without specific drying unless otherwise stated. Anhydrous THF was obtained by filtration through alumina drying columns. Commercial reagents were used as supplied, or purified by standard techniques where necessary. Flash column chromatography was performed using 230-400 mesh silica, with the indicated solvent system according to standard techniques. Analytical thin-layer chromatography (TLC) was performed on precoated glass-backed or aluminum-backed silica gel plates. Visualization of the developed chromatogram was performed by UV absorbance (254 nm) and/or stained with aqueous potassium permanganate solution or an acidic vanillin solution. Infrared spectra ($\nu_{\text{max}}, \text{FT-IR ATR}$) were recorded in reciprocal centimeters (cm$^{-1}$). Nuclear magnetic resonance spectra were recorded on 400 MHz spectrometers. Chemical shifts for $^1$H NMR spectra are recorded in parts per million (ppm) from tetramethylsilane with the solvent resonance as the internal standard (chloroform: $\delta = 7.26$ ppm, D$_2$O: $\delta = 4.79$ ppm, DMSO $\delta = 2.50$ ppm). Data is reported as follows: chemical shift (multiplicity [$s =$ singlet, $d =$ doublet, $t =$ triplet, $q =$ quartet, sept = septet, $m =$ multiplet,
br = broad, app = apparent, coupling constant (in Hz), integration and assignment. $^{13}$C NMR spectra were recorded with complete proton decoupling. Chemical shifts are reported in ppm from tetramethylsilane with the solvent resonance as the internal standard ($^{13}$CDCl$_3$: 77.16 ppm, ($^{13}$CD$_3$)$_2$SO: $\delta$ = 39.5 ppm). Melting points are uncorrected. Observed rotations were recorded at the indicated temperature (T °C) and were converted to the corresponding specific rotations. **Preparation of Sulfoxides 1a-e, 8.** Sulfoxides were obtained from commercial sources (1f-i), or by oxidation from the corresponding sulfides (1a-e, 8) with mCPBA or H$_2$O$_2$.**39,40,41,42,43,44,33** ($S$)-1-Methanesulfinyl-4-methylbenzene (($S$)-1a) was prepared according to the Jackson method**45 (er 97:3).

**Preparation of N-Boc, N-CO$_2$Me and N-CO$_2$Et Sulfoximines (2,3,4,9,10,11)**

**General Procedure 1** To a suspension of the sulfoxide (0.6 mmol), carbamate (0.9 mmol), MgO (97 mg, 2.4 mmol) and Rh$_2$(OAc)$_4$ (7.0 mg, 2.5 mol%) in CH$_2$Cl$_2$ (6 ml) was added PhI(OAc)$_2$ (290 mg, 0.90 mmol) at rt. The resulting mixture was stirred for 8 h at 40 °C. The reaction mixture was filtered through a pad of Celite and concentrated *in vacuo* and the resulting residue was purified by flash chromatography (SiO$_2$) to the give $N$-substituted sulfoximine.

**tert-Butyl [methyl(4-methylphenyl)oxido-$\lambda^6$-sulfanylidene]carbamate (2a)** Prepared according to **General Procedure 1** using sulfoxide 1a (97 mg, 0.63 mmol) and tert-butylcarbamate (111 mg, 0.945 mmol). Purification by flash chromatography (50% EtOAc/hexane) afforded $N$-Boc sulfoximine 2a (158 mg, 98%) as a white solid. $R_f$ = 0.5 (50% EtOAc /hexane); m.p. = 108-112 °C; IR (film) $\nu_{\text{max}}$ (cm$^{-1}$): 3034, 2980, 2934, 1664, 1267, 1149, 864, 783; $^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 7.84 (app d, $J$ = 8.3 Hz, 2H), 7.37 (app d, $J$ = 8.3 Hz, 2H), 3.21 (s, 3H), 2.44 (s, 3H), 1.38 (s, 9H); $^{13}$C{$^1$H} NMR (101 MHz, CDCl$_3$): $\delta$ 158.0, 144.9, 135.8 (2C), 130.4 (2C), 127.5, 80.6, 45.0, 28.2 (3C), 21.7; HRMS (ESI-TOF) m/z: calcd for C$_{13}$H$_{20}$NO$_3$S$^+$ [M+H]$^+$ 270.1164; found 270.1175.

(30) Performing the reaction with H2NBoc using methyl tolyl sulfide in place of the sulfoxide 1a under otherwise identical conditions gave the corresponding N-Boc methyl tolyl sulfilimine 2j in 53% conversion and 34% yield following flash chromatography on silica. Sulfoxide 1a was also formed in 37% (determined by 1H NMR of crude reaction mixture by comparison against 1,3,5-trimethoxybebzene as an internal standard).

(31) Lack of reactivity of these substrates may be due to the coordinating properties of the amine deactivating the catalyst, or subtle changes in nitrogen nucleophilicity or N-H acidity.
