1. Introduction

Allergic rhinitis (AR) is an inflammatory disorder of nasal mucosa with a high prevalence that affects people of all ages [1]. AR is a type I allergic disease by IgE with nasal itching, paroxysmal sneezing, nasal hypersecretion, nasal congestion, and other symptoms [2]. AR has developed into a global public health problem. It is not a fatal disease, but it is the basis of many complications and can severely affect the quality of life without effective treatment [3]. Mast cells (MCs) have been considered key effector cells in allergic reactions, and the IgE on them causes an allergic reaction. When patients are exposed to allergens again, allergen-specific IgE will combine with the allergens, resulting in the rapid release of mediators such as histamine (HIS) causing nasal reactions such as sneezing, nasal discharge, and nasal itching [4]. In addition, the production of cytokines such as HIS, tumor necrosis factor-α (TNF-α), and leukotriene (LT) can promote the inflow of inflammatory cells and further aggravate AR [5]. Xu reported that inhibition of toll-like receptor 4 (TLR4) on improving the AR via NF-κB and TNF receptor-associated factor 6 (TRAF6) played a key role in the TLR4-induced NF-κB activation [6]. Moreover, Hua’s team found that the native monocytes in AR patients were with the interleukin (IL)-6 up-regulated [7]. Piao’s team reported that Saikosaponin A inhibited the IL-6/ROR-γt/STAT3 pathway to improve AR [8].

Saposhnikovia divaricata (SD), the dried root of Saposhnikovia divaricata (Turcz.) Schischk, is a traditional Chinese medicine with anti-inflammatory and antiallergic effects [9, 10]. Li has found SD protected arthritis rats and inhibited the level of inflammatory factors in serum [11].
Moreover, Wang’s team observed the amelioration of SD treatment on FITC-induced allergic mice [12]. In particular, researchers studying the effects of polysaccharides of SD on AR races found it can inhibit the secretion of IgE, HA, and LTC4 [13]. In conclusion, SD has anti-inflammatory and antiallergic effects, but the biological mechanisms involved are not well defined. Therefore, we constructed AR model mice by ovalbumin (OVA) to observe the changes in behavioral and histopathological damage in mice after the action of SD and explored the biological mechanism by western blot (WB), immunohistochemistry (IHC), quantitative real-time PCR (qRT-PCR), and other techniques.

Besides, in recent decades, scientists found intestinal microflora was essential for host immune function, energy metabolism, and intestinal permeability [14]. Studies have demonstrated that the intestinal microflora could regulate type 2 immunity, regulate basophil hematopoiesis, and determine the trend of the host immune response [15]. What is more, a study has reported that Clostridium butyricum could promote the expression of IL-10 by antigen-specific B cells, leading to improved immune indicators in AR patients with the downregulation of IgE and Th2 [16]. Especially, scientists revealed that colon RORγ Treg cells were induced by IL-6 which was related to intestinal microflora. Therefore, this study explored the correlation between the etiology of AR and intestinal microecology by 16s rDNA high-throughput sequencing to provide new targets for the prevention and treatment of AR.

2. Materials and Methods

2.1. Aqueous Extract Preparation. In short, the SD that was provided and identified by the pharmacy of the author’s hospital was decocted twice with 10 times and 8 times volume water, respectively, for 1 h each time, and the decoction was filtered by No.3 filter paper; the aqueous extract was concentrated using a rotary evaporator at 60°C and was vacuum dried [11]. Each 1 g of the concentrated aqueous extract is equivalent to 20 g of the original drug.

2.2. Animal Grouping. The male BALB/c mice (6 weeks) were purchased by Shanghai Lingchang Biotech Co., Ltd. They were housed in a standard specific pathogen free grade environment with a free diet and light dark alternation with 14h light and 10h dark. The 24 mice were divided into three groups, namely, the control group, the AR group, and the SD group. Ovalbumin (OVA) (95%, 257–264, Sigma, USA) was prepared with 0.4% aluminum hydroxide to a concentration of 0.2 mg/mL. On the 1st day, the mice in AR and SD groups were dosed with an equal volume of saline by gavage. On the 14th, and 21st day, the mice were intraperitoneally injected with 0.5 mL OVA. On the 22nd day, the mice in the AR and SD groups were dosed daily intranasally with 20 μL of 25 mg/mL OVA for 14 days to consolidate allergic reaction. At the same time, the mice in the SD group were administered 16 mg/kg of SD aqueous extracts by gavage for 14 days according to the conversion of animal dose to a human dose based on body surface area [17], and mice in other groups were dosed with an equal volume of saline by gavage.

4. Animal Behavioral Observations

On the day after the last gavage, the number of sneezing and rubbing of the noses of each mouse was observed individually for 15 min on the final day of gavage.

5. Sample Preparation

On the day after the last gavage, nasal lavage fluid (NLF) was collected for the enzyme-linked immunosorbent assay (ELISA) and cytometry assay. The way of collecting the NLF was as Cho’s team described [18]; in brief, two consecutive volumes of 350 μL of PBS through the catheter (24G IV) that was inserted into the pharyngeal opening were instilled, and the NLF was collected from the nostrils. Subsequently, blood was extracted from the mouse orbit, the supernatant of blood was collected by centrifugation, and the serum was stored at −80°C. After euthanasia, the murine nasal maxillae were removed and immersed for fixation in 10% neutral formalin solution for 24 h; then, the intact nasal cavities were left to be fixed in 4% paraformaldehyde for histopathological examination.

5.1. Staining Analysis of Tissue Sections. After dewaxing and dehydrating, paraffin sections (4 μm) were stained by the stain kits of hematoxylin-eosin (H&E), periodic acid-Schiff (PAS), and toluidine blue (TB) stains according to the routine steps [19–21]. Moreover, the sections were dehydrated again, and then, they were mounted with neutral gum and examined by microscopy (ECLIPSE E100, Nikon, Japan). The sections by H&E stain were scored according to the degree of a dense arrangement of cells and the degree of mucosal swelling, the PAS stain was used to observe the number of goblet cells, and the TB stain was used to count the number of mast cells. In PAS stain, goblet cells are purplish-red, and nuclei are blue. In TB stains, the mast cells are dark purple.

5.2. Enzyme-Linked Immunosorbent Assay. The levels of immunoglobulin E (IgE), histamine (HIS), leukotriene B4 (LTB4), IL-2, 4, 5, 6, 10, 17, interferon-γ (IFN-γ), tumor necrosis factor-α (TNF-α), transforming growth factor-β1 (TGF-β1) in serum, or NLF were measured by ELISA according to instructions. The ELISA kits of IgE (MM-0056M1), HIS (MM-0548M1), LTB4 (MM-0041M1), IL-4 (MM-0165M1), IL-5 (MM-0164M1), IFN-γ (MM-0182M1), IL-6 (MM-0163M1), and IL-17 (MM-0170M1) were purchased from Jiangsu Meimian, Co., Ltd., China. Moreover, the IL-2 and TGF-β1 ELISA kits were provided by Shanghai Enzyme-linked Biotechnology Co., Ltd., China.
5.3. Cell Counting. After centrifugation, the precipitate of NLF was resuspended in 1 mL PBS (100 mM) supplemented with 1% bovine serum albumin (BSA) (G5001, Servicebio, China). Eosinophils, neutrophils, and lymphocytes were stained by Wright’s-Giemsa stain (CO133, Beyotime, China) for cell counting [22]. The number of cells was counted by using a hemocytometer.

6. Immunohistochemistry (IHC)

After dewaxing and dehydrating, the tissue section (4 µm) was subjected to citrate antigen retrieval solution for antigen retrieval, and endogenous peroxidase of it was blocked by H2O2. Moreover, 3% BSA was used to block the tissue section. Subsequently, the NF-κB p65 (1:200, AF5006, Affinity, US) and p-STAT3 (1:200, AF3293, Affinity, US) antibodies were incubated with the sections separately at 4°C overnight. After incubation by the corresponding secondary antibody, tissue sections were sequentially stained by a DAB kit (G1212, Servicebio, China) and hematoxylin (G1340, Servicebio, China) [23]. Lastly, they were dehydrated and mounted. Microscopy was used for observation and analysis. The positive expression was brown-yellow, and the nuclei were blue.

6.1. Quantitative Real-Time PCR (qRT-PCR). Generally speaking, after total RNA was extracted from mouse nasal mucosa by using the Trizol kit (B511311, Sangon Biotech, Shanghai, CHN), and reverse transcription was performed by using the HiFiScript cDNA Synthesis Kit (CW2569, CWBIO, Beijing, CHN). PCR was carried out under the following conditions by SYBR Premix Ex TaqII according to instructions, 95 °C for 10 min and 95 °C for 15 s, then at 60 °C for 60 s, performed 40 cycles [24]. The data were processed by the relative quantitative method (2^−ΔΔCt). The primer information is shown in Table 1.

6.2. Western Blot (WB). The RIPA lysate buffer (P0013D, Beyotime, CHN) was used to obtain the total proteins from mouse nasal mucosa, and a BCA kit (pc0020, Solarbio, CHN) was used to measure the concentration of total proteins. Then, protein denaturation was used by way of 100°C boiling water for 5 min, and the proteins were separated by electrophoresis. Later, the polyvinylidene fluoride membranes were used to transfer proteins in electroblotting, and then they were blocked by 5% nonfat milk. After washing by TBST and incubating with the TLKR4 (1:2000, AF7017), TRAF6 (1:2000, AF5376), p-IκBα (1:2000, AF2002), IκBα (1:2000, AF5002), NF-κB p65 (1:1500, AF5006), ROR-γt (1:500, DF3196), p-STAT3 (1:2000, AF3293), STAT3 (1:2000, AF6294), and β-actin (1:10000, AF7018) antibodies at 4°C overnight, the samples reacted with the corresponding secondary antibody for 2 h at 25 °C next day. Moreover, an ECL chemiluminescence kit (PE0010, Solarbio, Beijing, CHN) was used to color the protein band; subsequently, the membranes with the protein band were imaged with a chemiluminescence instrument (610020-9Q, Qin Xiang, Shanghai, CHN). The antibodies were all provided by Affinity Biosciences Ltd., Co, USA.

6.3. 16S rDNA High-Throughput Sequencing. After euthanasia, the caecum contents of 5 mice in each group were taken and handed over to Suzhou PANOMIX Biomedical Tech Co., Ltd. The total DNA of intestinal contents of mice was quantified by NanoDrop 2000, and the quality of DNA was detected by 1.2% agarose gel electrophoresis. The genome was amplified by PCR to obtain the v4-v5 region of the bacterial 16SrRNA gene. The Vazyme VAHTSTM DNA Clean Beads were added to the purification and recovery of amplification products. The recovered products of PCR amplification were quantified by the Quant-iT PicoGreen dsDNA assay kit, and the quantitative instrument was a microplate reader (BioTek, flx800). According to the sequencing quantity requirements of each sample, each sample shall be mixed according to the corresponding proportion. The sequencing library was prepared with the TruSeq Nano DNA LT Library Prep kit of Illumina company, and then high throughput sequencing was started. Sequence denoising or OTU clustering was performed according to QIIME2 dada2 or VSEARCH, and subsequently, QIIME2 (2019.4) was also used for species composition, alpha diversity, and beta diversity analysis. Based on KEGG (Kyoto Encyclopedia of Genes and Genomes, https://www.genome.jp/kegg/) and MetaCyc [25] (Metabolic Pathways From all Sources, https://metacyc.org/) databases, the microbial metabolic function of samples was predicted to find out different pathways and obtain the species composition of specific pathways. The enrichment pathway analysis was carried out based on intestinal microflora that has significant differences in the abundance of groups.

6.4. Statistical Analysis. If the metrology data were normally distributed and conformed to the homogeneity of the variance test, it was analyzed by the Turkey test; if the data were in normal distribution but unequal variance, the data met the paired Student’s t-test. All data were analyzed by SPSS 16.0. software and expressed as the mean ± standard deviation, and P < 0.05 means the difference was statistically significant.

7. Results

7.1. SD Treatment Improved the Disease Behavior and Histopathological Injury of AR Mice. The observation of sneezing and rubbing of the nose behavior was performed to verify the improvement effect of SD on AR mice (Figures 1(a) and 1(b)). The numbers of sneezing and rubbing the nose in the AR group were significantly higher than those in the control group, while SD-treated mice reversed it (P < 0.01). The histopathological injury of nasal mucosal in AR mice was assessed by H&E, PAS, and TB stains. In the AR group compared to the control group, the degree of cellular disarrangement and mucosal swelling was much more severe (Figure 1(c)); the number of goblet cells and mast cells was significantly larger (Figures 1(d) and 1(e))

TB proteins were assessed by western blot (Figures 4(f)–4(m)). The degrees of TLR4, TRAF6, p-IkBα, and NF-κB were measured by IHC. The average optical density of NF-κB was both markedly higher compared to the control group, and in the SD group, the average optical density of NF-κB was significantly reduced (P<0.01). Moreover, all of the protein degrees were increased significantly in the AR group than those in the control group (P<0.01). In the SD group, they are all decreased compared to the AR group (P<0.01, P<0.05).

7.2. SD Treatment on AR Mice Could Improve Inflammation and Allergy. The levels of cytokines related to inflammation and allergy in the serum were measured by ELISA (Figures 2(a)–2(i)). The levels of IgE, HIS, LTB4, IL-4, IL-2, IL-5, and TNF-α in the AR group were significantly higher than those in the control group, and SD treatment on AR mice could inhibit those levels notably (P<0.01). Moreover, the number of IL-2, IL-10, and IFN-γ was much lower in the AR group compared to the SD group, and the SD treatment could increase those levels markedly (P<0.01).

In the NLF, the levels of IL-6, IL-17, and IL-4 were inhibited notably with SD treatment on AR mice (P<0.01) (Figures 2(j), 2(l) and 2(m)), while the IL-10 and TGF-β1 levels were raised (P<0.01) (Figures 2(k) and 2(n)). The numbers of eosinophils, leukocytes, lymphocytes, and neutrophils were significantly up-regulated in the AR group compared to the control group, and they were markedly down-regulated after SD treatment (P<0.01) (Figures 2(o)–2(r)).

7.3. SD Treatment Regulated the TLR4/TRAF6/NF-κB and IL-6/ROR-γt/STAT3 Pathways in the Nasal Mucosa of AR Mice. The expression levels of NF-κB p65 and p-STAT3 were measured by IHC. The average optical density of NF-κB p65 and p-STAT3 was both markedly higher compared to the control group, and in the SD group, the average optical density of NF-κB p65 and p-STAT3 was significantly reduced (P<0.01) (Figures 3(a) and 3(b)).

The mRNA levels of TLR4, TRAF6, IL-6, ROR-γt, and STAT3 mRNA were measured by qRT-PCR (Figures 4(a)–4(e)). They were up-regulated in the AR group compared to the control group, while they were markedly reduced in the SD group than those in the AR group (P<0.01, P<0.05). The degrees of TLR4, TRAF6, p-IκBα/IκBα, and NF-κB proteins were assessed by western blot (Figures 4(f)–4(m)). Moreover, SD treatment could markedly antagonize the above trend (P<0.01).

7.4. SD Improved the OVA-Induced AR by the Intestinal Microflora Modulation. The effects of SD on the community diversity of intestinal microbial in AR mice were tested by 16S rDNA high-throughput sequencing. After processing the abundance table of ASV/OTU by the qiime feature-table rarely function in QIME2, as shown in Figure 5(a), the number of units varies at each level (phylum, class, order, family, genus, and species) in different groups was counted. Moreover, in the genus level, the top 20 shown in Figure 5(b) are Pseudomonas, Bifidobacterium, Ruminococcus, Allobaculum, Parabacteroides, and so on. The alpha diversity analysis of intestinal flora by different indexes is shown in Figure 5(c). In the SD group compared to the AR group, the alpha diversity of Pielou’s evenness has a significant difference (P<0.05). In Shannon and Simpson indexes, there are also significant differences in the SD group compared with the control group (P<0.05). According to the beta diversity analysis of Jaccard and unweighted unifrac based on PCoA, there were differences between the control group, the AR group, and the SD group (Figure 5(d)).

7.5. Analysis of Species Differences of the Intestinal Microflora among Different Groups. The marker species were analyzed by LDA effect size analysis (Figure 6(a)). c_Bacilli, o_Lactobacillales, and f_Lactobacillaceae were the top 3 with the highest abundance in the control group; o_Defferrribacterales, g_Mucispirillum, and c_Defferrribacteres were the top 3 with the highest abundance in the AR group; c_Clostridia, o_Clostridiales, and f_Ruminococcaceae were the top 3 with the highest abundance in the SD group. The distribution of the relative abundance of marker species (Cytophagales, Burkholderia, Alteromonadales, Lactococcus, and Clostridiaceae) in different groups is shown in Figure 6(b), and it

Figure 3: Continued.
showed that the abundance of these markers was significantly changed in the AR mice after SD treatment. The enrichment analysis on MetaCyc and KEGG pathways was counted for marker species to find out the metabolic pathways with a potential high correlation (Figures 7(a) and 7(b)). The enrichment pathways were the L-arginine degradation II, glycogen degradation II, superpathway of polyamine biosynthesis III, and isoprene biosynthesis II.
Figure 5: The effects of SD treatment on the intestinal microbial diversity of AR mice (n = 5). (a) The statistics of microbial taxa at phylum, class, order, family, genus, and species levels. There was large species abundance at the family and genus level. (b) The relative species abundance histograms on the genus. (c) The boxplots of the alpha diversity index. The Chao1 and observed species indexes are used to analyze the abundance. Shannon and Simpson are used to analyze diversity, the faith’s PD index is used to characterize evolution-based diversity, Pielou’s evenness index is used to characterize evenness, and Good’s coverage index represents coverage. (d) The beta diversity was analyzed by PCoA that was based on the Bray–Curtis, Jaccard, unweighted UniFrac, and weighted UniFrac. All error bars represent the mean ± standard deviation. SD: Saposhnikovia divaricata, AR: allergic rhinitis, and PCoA: principal co-ordinates analysis.
paths (Figures 8(a)–8(d)). In the L-arginine degradation II (AST) pathway, *Pseudomonas* is a common bacterium of the three groups, and its relative abundance ranks first (Figure 8(a)). In the glycogen degradation II (eukaryotic) pathway and the superpathway of polyanamine biosynthesis III, *Pseudoalteromonas* and *Vibrio* had the largest abundance in the control group (Figures 8(b), (c)). Interestingly, in the isoprene biosynthesis II (engineered) pathway, there is only *Corynebacterium* in the control and SD groups (Figure 8(d)).

8. Discussion

Traditional Chinese medicine has a definite and stable role in the prevention and treatment of AR with the advantages of overall regulation, multidirectional and multitarget [26]. Lenon studied the effect of a Chinese herbal formula (RCM-101) on rat peritoneal mast cells that inhibited HIS, LTB4, and prostaglandin E2 [27]. Yu-Ping-Feng-San (YPFS), a Chinese herbal medicine formula, was proved beneficial for treating adult AR [28], and Chen found that the potential therapeutic effect of YPFS on AR mice may be via T helper 1 and 2 [29]. SD was a key medicine of YPFS, which has been reported to be inhibiting the immunoregulatory mediators, TNF-α, IFN-γ, and IL-1β, in U937 cells [30]. Therefore, this study explored the effect and biological mechanism of SD on AR mice and proved that SD could improve disease behavior and histopathological injury.

Especially, SD reduced the number of mast cells in the nasal mucosa and the levels of inflammatory factors in the serum and NLF of AR mice in this study. Mast cells are the key effector cells of anaphylaxis and play an important role in the regulation of immune response [31]. Researchers found that the high level of IgE was related to the accumulation of mast cells [32], and IgE was a key receptor of mast cell degranulation, that is, the basis of type I hypersensitivity and inflammation [33]. The multiple inflammatory mediators of MCS degranulation and metabolites generated by membrane phospholipid metabolism are involved in the nasal allergic response to AR, such as HIS and LT [34], and they are strongly associated with the pathological manifestations of sneezing, scratching the nose, and tissue edema in AR [35]. LTB4 is key for the activation of mast cells and an attractant for their progenitor, which initiates inflammatory responses and promotes the release of inflammatory cytokines [36, 37]. What is more, a study reported that in an HDM-induced eosinophilic airway-inflammation mouse model, inhibition of LTB4 receptors restrained the number of eosinophils and the levels of IL-4,

Figure 7: Continued.
5, and 13 to relieve pulmonary inflammation [38]. In short, this study observed that SD treatment on AR mice can improve sneezing and rubbing of the nose, reduce nasal mucosa swelling, and inhibit the levels of inflammatory cells and factors, which may be related to the reduction in IgE, HIS, and LTB4.

In addition, we studied the expression degrees of the TLR4/TRAF6/NF-κB and IL-6/ROR-κt/STAT3 pathways by IHC, qRT-PCR, and WB. A study on patients with persistent allergic rhinitis found that the TLR4 mRNA level was significantly higher compared to the control group [39]. He inhibition of TLR4/TRAF6/NF-κB signaling improved AR, and Wang reported the alleviation of miR-146a on the inflammation in AR mice by inhibiting the TLR4/TRAF6/NF-κB pathway [40]. Besides, Piao’s team reported that Saiskosaponin A attenuated the AR via regulating the levels of the IL-6/ROR-κt/STAT3/IL-17/NF-κB pathway. It has been reported that MCs could amplify the immune response of T cells in the presence of TLR4 which is required for the induction of immune responses by MCs [41]. This study observed that SD restrained the protein levels of the TLR4/TRAF6/NF-κB and IL-6/ROR-κt/STAT3 pathways, which may be the one of reasons that SD improved AR.

In recent decades, studies have found that the dysbiosis of intestinal microflora was closely related to the development of allergic diseases [42]. Germ-free mice have a significantly lower density of mast cells in the small intestine than normal mice, and the migration of mast cells from the blood to the intestine is also associated with intestinal microflora [43]. Studies have demonstrated that the gut microbiota could regulate type 2 immunity, regulate basophil hematopoiesis, and determine the trend of the host immune response [15]. Besides, a study has reported that Clostridium butyricum could promote the expression of IL-10 by antigen-specific B cells, leading to improved immune indicators in AR patients with the downregulation of IgE and Th2 [16]. In this study, we found dysbiosis in the intestinal microflora of AR mice, and after SD treatment, the

intestinal microflora abundances were changed. The abundances of Bacteroidetes, Proteobacteria, and Firmicutes in AR mice were significantly different from those in control mice. A study reported that Bacteroidetes was related to the improvement effect of the compound small peptide of Chinese medicine on intestinal immunity in mice [44]. Moreover, Burkholderia, which belonged to Proteobacteria, in intestinal contents of fish was increased by the growth-
promoting traditional Chinese medicine treatment [45]. Kim’s team reported that the abundance of Firmicutes was decreased when atopic dermatitis in mice was improved [46]. Similarly, this analysis of intestinal microflora in this study reported that those microflora may play a role in the improvement of AR, which deserves further study. The interaction and biological mechanism between AR and intestinal microflora have the value of further exploration. Of course, the analysis results of the intestinal microflora are all predictions. If the sample number can be increased, a more accurate analysis of the intestinal microflora can be carried out. In summary, this study provides experimental evidence for the future development of SD intervention in AR and provides new ideas and the basis for the development of new drugs against allergic rhinitis in traditional Chinese medicine.

9. Conclusions

To summarize, this paper proved the improving effect of SD on behavior and histopathology of AR mice, and SD treatment inhibited the levels of proinflammatory and immune mediators (IgE, HIS, LTB4, IL-4, 5, 6, 17, TNF-α, and TGF-β1) and raised the levels of anti-inflammatory mediators (IL-2, 10, and IFN-γ) in OVA-induced AR mice. Moreover, SD treatment regulated the levels of NF-κB, TLR4, TRAF6, p-IκBα/1xBa, ROR-γt, and p-STAT3/STAT3 proteins and intestinal microflora in AR mice. This study suggested that the improvement effect of AR by SD treatment is related to the TLR4/TRAF6/NF-κB, IL-6/ROR-γt/STAT3 pathways and intestinal microflora modulation. The results of this study provide a new idea and the basis for traditional Chinese medicine on AR treatment.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Ethical Approval

All animal experiments were performed with the approval of the Animal Experimentation Ethics Committee of Zhejiang Eyong Pharmaceutical Research and Development Center (certificate no. SYXK (Zhe) 2021–0033), and the experiments were conducted strictly following the legal requirements.

Conflicts of Interest

The authors declare that they have no conflicts of interest.
