Abstract

We show how the Newton-Hooke (NH) symmetries, representing a nonrelativistic version of de-Sitter symmetries, can be enlarged by a pair of translation vectors describing in Galilean limit the class of accelerations linear in time. We study the Cartan-Maurer one-forms corresponding to such enlarged NH symmetry group and by using cohomological methods we determine the general 2-parameter (in $D = 2 + 1$ 4-parameter) central extension of the corresponding Lie algebra. We derive by using nonlinear realizations method the most general group - invariant particle dynamics depending on two (in $D = 2 + 1$ on four) central charges occurring as the Lagrangean parameters. Due to the presence of gauge invariances we show that for the enlarged NH symmetries quasicovariant dynamics reduces to the one following from standard NH symmetries, with one central charge in arbitrary dimension $D$ and with second exotic central charge in $D = 2 + 1$.

1 Introduction

In the classification of all kinematical groups in \( D = 3 + 1 \) one finds the two nonrelativistic counterparts of \( dS \) and \( AdS \) symmetries - two Newton-Hooke (NH) cosmological groups generated by two NH nonrelativistic algebras \([1, 2, 3, 4]\). In comparison with the Galilei algebra, described by the generators \( J_{ij} \) (nonrelativistic rotation), \( P_i \) (space translations), \( K_i \) (nonrelativistic boosts) and \( H \) (time translations) in NH algebra one relation is deformed for the finite value \( R \) of nonrelativistic (A)dS radius

\[
[H, P_i] = \pm \frac{K_i}{R^2} \left( \begin{array}{c}
+ : dS \text{ case} \\
- : AdS \text{ case}
\end{array} \right).
\] (1.1)

In arbitrary dimension \( D \) one can introduce one central charge described by the mass parameter \( m \)

\[
[P_i, K_j] = m \delta_{ij}.
\] (1.2)

If \( D = 2 + 1 \) one can add second “exotic” central charge \( \theta \) \([5, 6, 7, 8, 3, 9]\)

\[
[K_i, K_j] = \theta \epsilon_{ij} \quad [P_i, P_j] = -\frac{\theta}{R^2} \epsilon_{ij}.
\] (1.3)

Recently the NH symmetries were enlarged by adding the constant accelerations, described by the generator \( F_i \) \([10]\). We denote corresponding algebra by \( \hat{\text{NH}} \) and list below the relations satisfied by new generators \( F_i \), in arbitrary dimension \( D \) with central extensions included:

\[
[J_{ij}, F_k] = \delta_{ik} F_j - \delta_{jk} F_i, \quad (1.4a)
\]
\[
[H, F_i] = 2K_i, \quad (1.4b)
\]
\[
[P_i, F_j] = [F_i, F_j] = 0, \quad (1.4c)
\]
\[
[K_i, F_j] = \mp 2m R^2 \delta_{ij}, \quad (-dS, +AdS). \quad (1.4d)
\]

We see that the relation (1.4d) does not provide a finite limit \( R \to \infty \); in order to obtain such an Galilean limit we should introduce \( R \)-dependent Newton-Hooke mass parameter

\[
m \longrightarrow m(R) = \mp \frac{c}{R^2}. \quad (1.5a)
\]

In such a way the relation (1.2) takes the form

\[
[P_i, K_j] = \mp \frac{c}{R^2} \delta_{ij} \quad (1.5b)
\]

and in the Galilean limit we obtain

\[
[P_i, K_j] = 0, \quad [K_i, F_j] = 2c. \quad (1.6)
\]
in accordance with the formulae introduced in [11]. Further if $D = 2 + 1$, 
one can introduce two “exotic” central charges $\theta, \theta'$, satisfying besides the 
relations (1.3) the following relations [10]

\[
\begin{align*}
[P_i, F_j] &= 2 \theta \epsilon_{ij} \quad (1.7a) \\
[F_i, F_j] &= \theta' \epsilon_{ij} \quad (1.7b)
\end{align*}
\]

One of the aims of this paper is to enlarge the NH algebra by adding another 
vectorial Abelian generator $R_i$, and introduce a new extension of NH 
algebra, which we call doubly enlarged $\tilde{\text{NH}}$ algebra. The new algebra de-
scribe the symmetries of a class of nonrelativistic reference frames which are 
characterized also by a relative acceleration linear in time in the flat limit 
$R \to \infty$.

We consider a group element of this algebra and we construct the Cartan-
Maurer one-forms\footnote{Some of the calculations with forms have being done using the Mathematica code for differential forms EDC \cite{12}.} from which we can calculate the nontrivial Eilenberg-
Chevalley cohomology, providind the non-trivial closed invariant two forms 
which determine the central extension.\footnote{See for example \cite{13}.} In any dimension $D$ the $\tilde{\text{NH}}$ Lie 
algebra has two central charges, and the number of central charges in $D = 
2 + 1$, similarly like for $\hat{\text{NH}}$ Lie algebra \cite{10}, is equal to four.\footnote{We disregard here in $D = 2 + 1$ the “trivial” central extension due to the deformation of the commutator $[H, J]$, where $J_{ij} = \epsilon_{ij} J$.}

We further study the physical consequences of the additional generators 
$F_i, R_i$. We construct the action of a particle with $\tilde{\text{NH}}$ symmetries, by the 
method of non-linear realizations \cite{14}. The action can be written as sum of 
WZ terms multiplied by central charge parameters. For a generic dimension 
$D$ the lagrangian depends on two parameters, but exceptionally if $D = 2+1$ 
it depends on four parameters. The parameters appearing in the lagrangean 
are (besides the $dS$ radius $R$) in one to one correspondence with the central 
extensions of the $\tilde{\text{NH}}$ algebra.

The consistency of the field equations imply the existence of one (two in 
$D = 2 + 1$) relations among the two (four) dimensionfull lagrangean parameters. These constraints permit the existence of two local gauge invariances 
of the lagrangean. If a suitable gauge fixing is chosen the gauge-fixed action 
can be identified with the one considered in \cite{3, 9}. We also consider the re-
striction to the first order $\tilde{\text{NH}}$ quasi lagrangean by imposing the vanishing of 
the Golstone bosons associated to generators $\bar{R}$. If we impose some covariant 
relations representing inverse Higgs mechanism \cite{15} we recover the $\tilde{\text{NH}}$ quasi 
invariant higher lagrangean of reference \cite{10}.

The plan of the paper is as follows: in section 2 we will introduce the 
double enlarged $\tilde{\text{NH}}$ algebra and its central extension; the case $D = 2 + 1$
is considered separately. In section 3 we construct the most general $\hat{\text{NH}}$ invariant first order lagrangean and its gauge invariances. We also show that the higher order actions considered in [10, 11] can be derived from our linear action. Finally in section 4 we provide some conclusions.

2 Doubly Enlarged Newton-Hooke Symmetries

The nonrelativistic de-Sitter and anti de-Sitter symmetries (see (1.1)) describe respectively the nonrelativistic expanding and nonrelativistic oscillating universes. The cosmological constant $\kappa = \frac{1}{R}$ describes the time scale determining the rate of expansion or the period of oscillations of the universe. When $\kappa \to 0$ we obtain the Galilean group and the standard flat nonrelativistic space-time.

The Newton-Hooke algebra describing nonrelativistic (anti)-de-Sitter symmetries [9, 17] was extended in [11] to acceleration - extended Newton-Hooke algebra (see (1.1)–(1.6)). The change of nonrelativistic space-time $(\vec{x} = (x_1, \ldots x_d), t)$ under the transformations of the acceleration - extended NH group are the following [11]

$$\delta x_i = a_i \cosh \frac{t}{R} + v_i R \sinh \frac{t}{R} + 2 b_i R^2 (\cosh \frac{t}{R} - 1) + \alpha_{ij} x_j$$
$$\delta t = t + a_0$$  (2.1)

with the following assignments of the parameters
- $a_i$ – spatial translations (generators $P_i$), dimension $[a_i] = L^1$
- $v_i$ – boosts (generators $K_i$), dimensions $[v_i] = L^0$
- $b_i$ – accelerations (generators $F_i$), dimensions $[b_i] = L^{-1}$
- $\alpha_{ij}$ – $O(d)$ space rotations (generators $I_{ij}$), dimensions $[\alpha_{ij}] = L^0$
- $a_0$ – time translation (generator $H$), dimension $[a_0] = L^1$.

Let us observe that in the flat limit $R \to \infty$ we obtain from (2.1) the following formulae for acceleration - enlarged Galilean transformations

$$\delta x_i = a_i + v_i t + b_i t^2 + \alpha_{ij} x_j$$
$$\delta t = t + a_0.$$  (2.2)

In this paper we propose to extend the formula (2.2) by adding subsequent term

$$\delta x_i = c_i t^3,$$  (2.3)

or for $R < \infty$

$$\delta x_i = 6 c_i R^3 (\sinh \frac{t}{R} - \frac{t}{R})$$  (2.4)
The transformations (2.1) and (2.4) leads to the following differential realization of the doubly enlarged \( \hat{\text{NH}} \) algebra on nonrelativistic space-time

\[
\begin{align*}
P_i &= \cosh \frac{t}{R} \frac{\partial}{\partial x_i}, & K_i &= R \sinh \frac{t}{R} \frac{\partial}{\partial x_i} \\
F_i &= 2R^2(\cosh \frac{t}{R} - 1)\frac{\partial}{\partial x_i} \\
R_i &= 6R^3(\sinh \frac{t}{R} - t)\frac{\partial}{\partial x_i} \\
H &= \frac{\partial}{\partial t}, \\
J_{ij} &= x_i \frac{\partial}{\partial x_j} - x_j \frac{\partial}{\partial x_i}.
\end{align*}
\] (2.5)

The algebra of these vector fields give the unextended version of the algebra \( \hat{\text{NH}} \)

\[
\begin{align*}
[H, P_i] &= \frac{K_i}{R^2}, & [H, K_i] &= P_i, & [H, F_i] &= 2K_i \\
[H, R_i] &= 3F_i, & [I_A, I_B] &= 0, & I_A &= (P_i, K_i, F_i, R_i) \\
[I_{ij}, I_k] &= \delta_{ik}I_j - \delta_{jk}I_i, & I_i &= P_i \text{ or } K_i \text{ or } F_i \text{ or } R_i \\
[I_{ij}, I_{kl}] &= \delta_{ik}I_{jl} - \delta_{il}I_{jk} + \delta_{jl}I_{ik} - \delta_{jk}I_{il}.
\end{align*}
\] (2.6)

Let us write this Lie algebra in terms of the dual formulation. We introduce the Lie-valued left-invariant Maurer-Cartan (MC) 1-form

\[
\Omega_1 = g^{-1}dg = L^H H + L^P_i P_i + L^K_i K_i + L^F_i F_i + L^R_i R_i + L^I_{ij} I_{ij}
\] (2.7)

where \( g \) is an general element of the group and \( L^H, L^P_i, L^K_i, L^F_i, L^R_i, L^I_{ij} \) are 1-forms, whose explicit form depends on the parametrization of the group element. The MC one-form verifies the MC equation \( d\Omega + \Omega \wedge \Omega = 0 \), in terms of the 1-forms L’s we have

\[
\begin{align*}
dL^H &= 0 \\
dL^P_i &= L^P_j \wedge L^I_{ij} - L^H \wedge L^K_i \\
dL^K_i &= L^K_j \wedge L^I_{ij} - \frac{1}{R^2} L^H \wedge L^P_i - 2L^H \wedge L^F_i \\
dL^F_i &= L^F_j \wedge L^I_{ij} - 3L^H \wedge L^R_i \\
dL^R_i &= L^R_j \wedge L^I_{ij} \\
dL^I_{ij} &= L^I_{ik} \wedge L^I_{kj}.
\end{align*}
\] (2.8)

If \( D = 2 + 1 \) the rotations \( I_{ij} \) reduce to Abelian rotation \( I_{ij} = \epsilon_{ij}I \), and the relations (2.8) take the following form:

\[
\begin{align*}
dL^H &= 0 \\
\end{align*}
\] **4**We consider the hyperbolic \( dS \) case (see \( \mathbb{1} \)). The trigonometric case is obtained by changing, \( R \rightarrow iR \) in all the equations.
\[ dL_i^P = \epsilon_{ij} L_j^P \wedge L^I - L^H \wedge L_i^K \]
\[ dL_i^K = \epsilon_{ij} L_j^K \wedge L^I - \frac{1}{R^2} L^H \wedge L_i^P - 2L^H \wedge L_i^F \]
\[ dL_i^F = \epsilon_{ij} L_j^F \wedge L^I - 3L^H \wedge L_i^R \]
\[ dL_i^R = \epsilon_{ij} L_j^R \wedge L^I \]
\[ dL^I = 0. \] (2.9)

where \( L^I_{ij} = \epsilon_{ij} L^I \).

Now we will construct the extended algebra \( \widehat{\text{NH}} \). In order to describe the central charges in arbitrary dimension one should look for the invariant closed 2-forms \( \Omega_2 \), with closure property \( d\Omega_2 = 0 \) following from the relations (2.8), (2.9), and write the 2-form, \( \Omega_2 = d\Omega_1 \) as bilinear exterior product of the MC 1-forms (see e.g. [13]). One obtains in arbitrary dimension \( D \) the following two nontrivial cohomology classes of rank 2:

\[ \Omega_2^{(c)} = L_i^F \wedge L_j^K - \frac{1}{2R^2} L_i^K \wedge L_j^P + 3L_i^P \wedge L_j^R \] (2.10a)
\[ \Omega_2^{(M)} = L_i^F \wedge L_j^R \] (2.10b)

In \( D = 2 + 1 \) one obtain besides the cohomology classes (2.10a-b) still two “exotic” cohomology classes, namely

\[ \widetilde{\Omega}_2^{(\theta)} = -\frac{1}{2R^2} \epsilon_{ij} L_i^P \wedge L_j^P + \frac{1}{2} \epsilon_{ij} L_i^K \wedge L_j^K \]
\[ -2\epsilon_{ij} L_i^F \wedge L_j^P - 2R^2(\epsilon_{ij} L_i^F \wedge L_j^F - 3 \epsilon_{ij} L_i^K \wedge L_j^R) \] (2.11a)
\[ \widetilde{\Omega}_2^{(\theta')} = \epsilon_{ij} L_i^R \wedge L_j^R \] (2.11b)

In order to obtain the Liouville one-forms \( \Theta_1^{(c)}, \Theta_1^{(M)}, \tilde{\Theta}_1, \tilde{\Theta}_1' \)

\[ \Omega_2^{(c)} = d\Theta_1^{(c)} \]
\[ \Omega_2^{(M)} = d\Theta_1^{(M)} \]
\[ \widetilde{\Omega}_2^{(\theta)} = d\tilde{\Theta}_1 \]
\[ \widetilde{\Omega}_2^{(\theta')} = d\tilde{\Theta}_1' \] (2.11c)

one should provide a parametrization of the group element.

From the forms (2.10a-b) we can construct the centrally extended Lie algebra in arbitrary dimension \( D \). The algebra is given by \( \widehat{\text{NH}} \) relations (2.6) with the commuting algebra of generators \( (P_i, K_i F_i, R_i) \) replaced by the non-vanishing commutation relations:

\[ [P_i, R_j] = -3c \delta_{ij} \] (2.12a)
\[ [K_i, P_j] = \frac{1}{2R^2} c \delta_{ij} \] (2.12b)
\[ [F_i, K_j] = -c \delta_{ij} \] (2.12c)
\[ [F_i, R_j] = -M \delta_{ij} \] (2.12d)

where \( c \) and \( M \) are two central charges.
If \( D = 2 + 1 \) from \((2.11)\) we obtain two additional central charges \( \theta, \theta'' \):

\[
\begin{align*}
[F_i, F_j] &= 4R^2 \theta \epsilon_{ij} \\
[P_i, P_j] &= \frac{1}{R^2} \theta \epsilon_{ij} \\
[F_i, P_j] &= 2 \theta \epsilon_{ij} \\
[K_i, K_j] &= -\theta \epsilon_{ij} \\
[K_i, R_j] &= -6R^2 \theta \epsilon_{ij} \\
[R_i, R_j] &= -\theta'' \epsilon_{ij}
\end{align*}
\]

(2.13)

We see therefore that our new enlarged \( \widehat{NH} \) algebra in \( D = 2 + 1 \) depends on two standard \( (m \text{ and } M) \) and two exotic \( (\theta \text{ and } \theta'') \) central charges.

3 Particle Lagrangian from Nonlinear Realizations

In this section we will construct the most general particle lagrangian (quasi) invariant under the group \( \widehat{NH} \) and its gauge invariances. We will use the method of non-linear realizations \[14\]. As we shall see the most general \( \widehat{NH} \) first order invariant action is endowed with gauge symmetries. We also discuss the corresponding \( NH \) first order quasi invariant lagrangian as well as the connection with the higher order lagrangian proposed in \([10]\).

3.1 General Reparametrization Invariant Action

Let us consider the coset of the unextended algebra \( \widehat{NH}_{SO(d)} \). We locally parametrize the coset as follows

\[ g = e^{iH} e^{xP} e^{K} e^{F} e^{R} \]

The (Goldstone) coordinates of the coset depend on the parameter \( \tau \) that parametrizes the world line of the particle (see for example \[10\]). The corresponding Maurer-Cartan one-form

\[ \Omega_1 = L^H H + L^P P_i + L^K K_i + L^F F_i + L^R R_i + L^I I_{ij} \]

(3.2)

In arbitrary dimension \( D \) the 1-forms \( L \) are

\[
\begin{align*}
L^H &= dt \\
L^P &= v_i \, dt + dx_i \\
L^K &= dv_i + 2w_i dt + \frac{1}{R^2} x_i dt \\
L^F &= dw_i + 3s_i dt
\end{align*}
\]
\( L_i^R = ds_i \). (3.3)

Substituting the one-forms in the formulae (2.10a,b) and (2.11a,b) one obtains the following formulae for the corresponding Liouville one-forms, satisfying the relations (2.11c)

\[
\Theta_1^{(c)} = \bar{w}^2 dt - \frac{1}{4 R^2} \bar{\varphi}^2 dt + \frac{\bar{w} \cdot \bar{\varphi}}{R^2} dt + \frac{1}{4} \frac{1}{(R^2)^2} x^2 dt - \frac{1}{2 R^2} \vec{v} \cdot d \vec{x} + \bar{\omega} d \bar{\varphi}
\]

\[-3 \bar{s} d \bar{x} - \frac{3}{2} \bar{s}^2 dt \] (3.4a)

\[
\Theta_1^{(M)} = -\bar{s} d \bar{w} - \frac{3}{2} \bar{s}^2 dt \] (3.4b)

and

\[
\tilde{\Theta}_1 = \epsilon_{ij} \left( \frac{1}{2} v_i dv_j - 2 w_i dx_j dt + 2 v_i w_j dt - 6 x_i s_j dt \right) + \frac{\epsilon_{ij}}{R^2} \left( v_i x_j dt - \frac{1}{2} x_i dx_j \right) - 2 \epsilon_{ij} R^2 \left( w_i dw_j - 3 s_i dv_j - 6 s_i w_j dt \right) \] (3.5a)

\[
\tilde{\Theta}_1'' = \frac{1}{2} \epsilon_{ij} s_i ds_j \] (3.5b)

In arbitrary dimension \( D \) the action is given by

\[
S = \int (c \Theta_1^{(c)} + M \Theta_1^{(M)})^* \] (3.6)

and in the \( D = 2 + 1 \) we have

\[
\tilde{S} = S + \int (\theta \tilde{\Theta}_1 + \theta'' \tilde{\Theta}_1'')^* \] (3.7)

where \(^*\) means pullback on the worldline of the particle parametrized by \( \tau \). One can fix the diffeomorphism invariance by choosing \( t = \tau \). In D dimensions the Lagrangean deduced from (3.6) has the following explicit form

\[
L_1 = c \left[ \left( \bar{w}^2 - \frac{1}{4 R^2} \bar{\varphi}^2 + \frac{\bar{w} \cdot \bar{\varphi}}{R^2} + \frac{1}{4} \frac{1}{(R^2)^2} x^2 \right) - 3 \bar{s} \cdot \bar{v} \right] + \left( \bar{s} \bar{w} + \frac{3}{2} \bar{s}^2 \right) - M \left( \bar{s} \bar{w} + \frac{3}{2} \bar{s}^2 \right) \] (3.8)

The field equations following from (3.8) are

\[
\frac{1}{2 R^2} \left( \frac{1}{R^2} x_i + \bar{v}_i \right) + \frac{w_i}{R^2} + 3 \bar{s}_i = 0 \] (3.9a)

\[
\frac{1}{2 R^2} \left( \bar{x}_i + v_i \right) + (3 \bar{s}_i + \bar{w}_i) = 0 \] (3.9b)

\[
c \left( \frac{1}{R^2} x_i + \bar{v}_i \right) + 2 c w_i + M \bar{s}_i = 0 \] (3.9c)

\[
M \left( \bar{w}_i + 3 \bar{s}_i \right) + 3 c \left( v_i + \bar{x}_i \right) = 0 \] (3.9d)
3.2 Gauge Invariances and Reduction to Oscillator Dynamics

From relations (3.9a) and (3.9c) follows as the consistency condition (if $\dot{s}_i \neq 0$)

$$M = 6cR^2.$$  \hfill (3.10)

If (3.10) is valid the pair of relations (3.9c,d) are the same as the relations (3.9a,d). The equation (3.9a,b) describe the following relations between the one-forms (3.3) ($L^x = L^x dt$, where $\dot{L}^x = \frac{dL^x}{dt}$)

$$\frac{1}{2R^2}\dot{L}^P_i + \dot{L}^F_i = 0,$$  \hfill (3.11a)

$$\frac{1}{2R^2}\dot{L}^K_i + 3\dot{L}^R = 0.$$  \hfill (3.11b)

We see that in field equations (3.11a-b) out of four functions $x_i(t)$, $v_i(t)$, $w_i(t)$, $s_i(t)$ two can be chosen arbitrary. Such a property reflects the presence (if condition (3.10) is satisfied) of two-parameter local gauge invariance. Indeed, the action (3.8) depends only on the following two linear combinations of the field variables.

$$u_i = w_i + \frac{x_i}{2R^2},$$  \hfill (3.12a)

$$y_i = s_i + \frac{1}{6R^2}v_i.$$  \hfill (3.12b)

Substituting (3.12a-b) into (3.8) one obtains

$$L_1 = c \left( \frac{\dot{u}^2}{2} - 9R^2\frac{\dot{y}^2}{2} - 6R^2y_i \cdot \dot{u}_i \right).$$  \hfill (3.13)

The dependence of $L$ on linear combinations (3.12a,b) means that the action (3.8) is invariant under the following two local gauge transformations, leaving the variables $u_i$ and $y_i$ invariant

$$\delta x_i = \epsilon_i \quad \delta w_i = -\frac{1}{2R^2}\epsilon_i,$$

$$\delta s_i = \eta_i \quad \delta v_i = -\frac{1}{6R^2}\eta_i.$$  \hfill (3.14)

By fixing the gauge invariances (3.14)

$$\epsilon_i = 2R^2w_i \Rightarrow \quad u_i = \frac{1}{2R^2}x_i, \quad w_i = 0$$ \hfill (3.15a)

$$\eta_i = 6R^2s_i \Rightarrow \quad y_i = \frac{1}{6R^2}v_i, \quad s_i = 0$$ \hfill (3.15b)

we obtain the following gauge-fixed form of the action (3.8)

$$L_1^{\text{fix}} = -\frac{c}{2R^2} \left( \ddot{v}^x x + \frac{1}{2} v^2 - \frac{1}{2} R^2 x^2 \right).$$  \hfill (3.16)
The field equations derived from (3.16) are
\[ \ddot{\vec{v}} + \dot{\vec{x}} = 0 \quad \ddot{\vec{v}} + \frac{1}{R^2} \ddot{\vec{x}} = 0, \] (3.17)
lead to the hyperbolic oscillator equation
\[ \dddot{\vec{x}} - \frac{1}{R^2} \dddot{\vec{x}} = 0 \] (3.18)
with the frequency described by the inverse of \( dS \) radius.

In \( D = 2 + 1 \) dimensions from (3.5a-b) one obtains the following part of the action depending on two exotic charges \( \theta, \theta'' \)
\[ L_2 = \theta \left[ \frac{1}{2} \epsilon_{ij} v_i \dot{v}_j - \frac{1}{2 R^2} \epsilon_{ij} x_i \dot{x}_j - 2 \epsilon_{ij} w_i \dot{x}_j + 2 \epsilon_{ij} v_i w_j - 6 \epsilon_{ij} x_i s_j + \frac{\epsilon_{ij}}{R^2} v_i x_j - 2 \epsilon_{ij} R^2 (w_i \dot{w}_j - 3 s_i \dot{v}_j - 6 s_i w_j) \right] + \frac{\theta''}{2} \epsilon_{ij} s_i \dot{s}_j . \] (3.19)

Introducing new variable \( u_i \) (see (3.12a)) one gets
\[ L_2 = \theta \left( -2 \epsilon_{ij} R^2 u_i \dot{u}_j + 2 \epsilon_{ij} v_i u_j + 12 \epsilon_{ij} R^2 s_i u_j + \frac{1}{2} \epsilon_{ij} v_i \dot{v}_j + 6 \epsilon_{ij} R^2 s_i \dot{v}_j \right) + \frac{\theta''}{2} \epsilon_{ij} s_i \dot{s}_j . \] (3.20)
the field equations are
\[ 2 \theta \epsilon_{ij} \left( 2 R^2 \dot{u}_j + v_j + 6 R^2 s_j \right) = 0 \] (3.21a)
\[ \epsilon_{ij} \left( \dot{v}_j + 2 u_j + 6 R^2 \dot{s}_j \right) = 0 \] (3.21b)
\[ 6 \theta R^2 \epsilon_{ij} \left( \dot{v}_j + 2 u_j \right) + \theta'' \epsilon_{ij} \dot{s}_j = 0 \] (3.21c)
by consistency (if \( \dot{s}_i \neq 0 \)) we have
\[ \theta'' = 36 R^4 \theta . \] (3.22)
In such a case the action (3.20) depends only on two variables (3.12a-b)
\[ L_2 = \theta R^2 \left( -2 \epsilon_{ij} u_i \dot{u}_j + 12 \epsilon_{ij} y_i u_j + 18 \epsilon_{ij} R^2 y_i \dot{y}_j \right) . \] (3.23)

The most general action in \( D = 2 + 1 \) is described by the sum of the action (3.8) and (3.19). If we write down the field equations it appears that one can derive the following equation
\[ A \dot{s}_i + B \epsilon_{ij} \dot{s}_j = 0 \] (3.24)
where
\[ A = M - 6c R^2 \quad B = \theta'' - 36 R^4 \theta . \] (3.25)
The solvability of Eq. (3.24) leads to
\[
\det \begin{pmatrix} A & B \\ -B & A \end{pmatrix} = 0 \quad \Rightarrow \quad A^2 + B^2 = 0 \quad \Rightarrow \quad A = 0, B = 0 \quad (3.26)
\]
i.e. we reproduce the constraints (3.10) and (3.22).

Using the conditions (3.15a-b) and (3.10), (3.22) one obtains the following general gauge-fixed action in \( D = 2 + 1 \)
\[
L_{\text{fix}} = L_{1|\vec{s} = 0} + L_{2|\vec{s} = 0} = -\frac{c}{4R^2} \left( 2v_i \dot{x}_i + \vec{v}^2 - \frac{1}{R^2} \vec{x}^2 \right) \\
+ \theta \epsilon_{ij} \frac{1}{2} \left( -\frac{x_i \dot{x}_j}{R^2} - 2 \frac{x_i v_j}{R^2} + v_i \dot{v}_j \right) \quad (3.27)
\]
which can be identified with the one presented in [9] (see formula (3.5a,b)) if we pass from \( dS \) to \( AdS \) case (\( R \to iR \)), parametrize velocity with opposite sign (\( v_i \to -v_i \)) and put \( m = -\frac{c}{2R^2}, \theta = \frac{\kappa}{2} \). One can state therefore that the physical content of our model is the same as in the case of standard Newton-Hooke symmetries, with the same number of generators as in Galilean case.

3.3 Relation with \( \hat{\text{NH}} \) Higher Order Lagrangean

Firstly we derive the \( \hat{\text{NH}} \) first order lagrangean from our results presented above. For that purpose we should put equal to zero the Goldstone fields associated with generators \( \vec{R} \), (\( \vec{s} = 0 \)). For dimension \( D \neq 2 + 1 \) the action density becomes \( L_{1|\vec{s} = 0} \), where the lagrangean \( L_1 \) is given by (3.8). Instead for \( D = 2 + 1 \) there is an extra term \( L_{2|\vec{s} = 0} \) with \( L_2 \) described (3.19).

Let us use the variables
\[
u_i = w_i + \frac{x_i}{2R^2}, \quad (3.28)
\]
\[
y_i = \frac{1}{6R^2} v_i. \quad (3.29)
\]

We can write the Lagrangeans as
\[
L_{1|\vec{s} = 0} = \tilde{c} \left( 2 \vec{u}^2 - \frac{1}{2R^2} \vec{v}^2 - 2v_i \cdot \dot{u}_i \right) \quad (3.30)
\]
\[
L_{2|\vec{s} = 0} = \theta' \left( \epsilon_{ij} u_i \dot{u}_j - \frac{1}{2R^2} \epsilon_{ij} v_i u_j - \frac{1}{4R^2} \epsilon_{ij} v_i \dot{v}_j \right) \quad (3.31)
\]
where \( \tilde{c} = \frac{c}{2}, \theta' = -4R^2 \theta \).

If we employ the covariant inverse Higgs mechanism [15], by putting \( L_i^K = L_i^P = 0 \) and using (3.3), (3.28) we obtain
\[
v_i = -\dot{x}_i \quad (3.32)
\]
\[
u_i = -\frac{1}{2} \dot{v}_i. \quad (3.33)
\]
From (3.30) and (3.31) we get the \( \hat{\text{NH}} \) higher order Lagrangean proposed in [10].
4 Conclusions

We demonstrated that the action constructed via Cartan-Maurer one-forms for extended NH groups with additional constant and linear acceleration generators \( (F_i, R_i) \) supplements only a gauge sector of the standard Newton-Hooke dynamics. To achieve such equivalence we have to reduce the number of central charges via suitably chosen relations \((3.10)\) and \((3.20)\). We recall that changing the sign of \( R^2 \) (see \((1.1)\)) we obtain from the hyperbolic oscillator (see \((3.18)\)) the standard one, with trigonometric solutions (see \([9]\)).

It seems therefore that if consider more general NH algebras with extra Abelian generators, the particle dynamics will be equivalent to the one describing ordinary NH particle. This is due the appearance of gauge symmetries associated the extra generators. It will be interesting to understand better such a property.

We have also seen that if we assume that Goldstone fields associated with \( \vec{R} \) vanish and we impose some covariant relations one recovers the \( \hat{\text{NH}} \) higher order lagrangians introduced in reference \([10]\).

Finally we would like to observe that the transformations \((2.1)-(2.4)\), for \( R \rightarrow \infty \), can be extended as follows

\[
x'_i = x_i + a_i(t).
\]

We get in such a way the reparametrization group of Newton’s equation of particle in the presence of nonrelativistic gravitational potential \( V(x,t) \) (see e.g. \([18]\)).

\[
\frac{d^2x_i}{dt^2} = \frac{\partial V}{\partial x_i} \tag{4.2}
\]

which is invariant under \((4.1)\) if \( V' = V - \ddot{a}_i x_i \). It seems interesting to consider the link between the extension of system \((4.2)\) for \( R \) finite and the enlarged NH symmetries of arbitrary order.

Acknowledgements

We acknowledge Roberto Casalbuoni, Gary Gibbons, Mikhail Plyushchay, Peter Stichel and Andrzej Trautmann for useful discussions. This work has been supported by the European EC-RTN project MRTN-CT-2004-005104, MCYT FPA 2007-66665, CIRIT GC 2005SGR-00564, Spanish Consolider-Ingenio 2010 Programme CPAN (CSD2007-00042) and by Polish MNiSW grant N N202 318534 (JL). We would like to thank the PH-TH Division at CERN for its hospitality where this works has started.
