\textbf{ABSTRACT}

\textbf{Context:} The long-term consumption of glucocorticoids (GCs) may induce serious adverse effects such as hypertension. There is sufficient evidence related to the benefit of walnuts on the cardiovascular system.

\textbf{Objective:} This study assesses the effect of methanol extract of walnut [*Juglans regia* L. (Juglandaceae)] on dexamethasone-induced hypertension and the possible mechanisms in Wistar rats.

\textbf{Material and methods:} Animals were randomized into control, kernel extract (100 and 200 mg/kg/d, orally), dexamethasone (0.03 mg/kg/d, subcutaneously), dexamethasone + kernel (100 and 200 mg/kg/d, separately), and dexamethasone + captopril (25 mg/kg/d, orally) groups. Animals were treated with water, kernel extract or captopril by gavage 4 d before and during 11 d of saline or dexamethasone treatment. On the 16th day, blood pressure (BP) was recorded and blood samples were collected to measure nitric oxide (NO). Animal hearts were frozen for measurement of malondialdehyde (MDA) and glutathione peroxidase (GPX).

\textbf{Results:} Dexamethasone increased the diastolic BP and MDA/GPX ratio in comparison with control group (128 ± 7 vs. 105 ± 3 mmHg, \(p < 0.05\) and 0.2 ± 0.046 vs. 0.08 ± 0.02, \(p < 0.05\)). Combination of dexamethasone and walnut (200 mg/kg) prevented the dexamethasone-induced diastolic hypertension (109 ± 3 vs. 128 ± 7 mmHg; \(p < 0.05\)), increased the GPX level (14.8 ± 1.46 vs. 5.1 ± 0.64 unit/mg, \(p < 0.05\)), reduced the MDA/GPX ratio (0.16 ± 0.015 vs. 0.2 ± 0.046) and improved serum NO level.

\textbf{Conclusion:} Similar to captopril, walnut extract normalized dexamethasone-induced hypertension. A part of this beneficial effect apparently involves maintaining balance of the redox system and NO production.

\textbf{Introduction}

Glucocorticoids (GCs) are used to treat many inflammatory diseases and cancers, and to prevent the rejection of organ transplants. However, the high doses and long-term consumption of these agents are associated with serious adverse effects, such as cardiovascular events, hypertension, diabetes mellitus, bone loss and fractures (Brunton et al. 2008). The incidence of hypertension in patients on long-term steroid therapy varies between 10 and 40\% (Seth & Aggarwal 2004). Treatment with GCs increases blood pressure (BP) in both groups of normotensive and hypertensive persons (Saruta et al. 1986). In addition, enhanced vascular sensitivity to GCs has been also reported in patients with essential hypertension (Walker et al. 1996).

Dexamethasone is a synthetic glucocorticoid with potent anti-inflammatory and immunosuppressant properties. It is useful in various inflammatory and autoimmune diseases and used for some clinical conditions, such as multiple myeloma, adrenal insufficiency and to prevent vasogenic oedema secondary to cerebral tumours (Ong et al. 2009b). Similar to other GCs, hypertension is a common side effect of chronic dexamethasone therapy. Sodium retention is not a mechanism of dexamethasone-induced hypertension (Ong & Whitworth 2011). Possible mechanisms include nitric oxide-reodox imbalance, increased total peripheral resistance and enhanced pressor response to vasoconstrictors (Ong et al. 2009b).

Although the increase in total peripheral vascular resistance is a feature of hypertension caused by dexamethasone, but on the basis of experimental studies, vasodilatory drugs, such as minoxidil (Ong et al. 2009a), beta-adrenergic receptor blockers (Wen et al. 1999), calcium channel blockers (Whitworth et al. 1994), allopurinol and xanthine oxidase inhibitors (Ong et al. 2007) are ineffective on corticosteroid-induced hypertension.

Food intake is an important factor for the prevention and treatment of cardiovascular diseases. Walnut [*Juglans regia* L. (Juglandaceae)], a well known and popularly nut has been seen in the food basket of some people in world. Walnut is rich in bioactive compounds, such as dietary fibre, folic acid and...
antioxidants. There is sufficient evidence related to its benefit in reducing cardiovascular risk factors (Kris-Etherton 2014). Human studies showed that walnut decreases the LDL cholesterol dose dependently, improves the endothelium-dependent vasodilation and reduces the total peripheral resistance (Ros et al. 2004; Cortés et al. 2006; West et al. 2010; Kris-Etherton 2014). With knowledge of the side effects of antihypertensive drugs, as well as the priority of prevention to treatment, in this study, we investigated whether walnut extract can prevent the dexamethasone-induced hypertension in rat.

Materials and methods

This study was approved by the national guidelines for conducting animal studies (Ethic committee permission no. K/91/127-Kerman University of Medical Sciences, Iran).

Dexamethasone was from Iran Hormone Company and sodium thiopental, which used for anaesthesia induction was from Biocheme, Kundl, Austria. The glutathione peroxidase (GPX) and serum nitrite level were measured using Randox (Northern Ireland, UK) and the Griess reagent (Promega Corp., Madison, WI) kits, respectively. Walnuts were prepared during September 2013 from Dehbakri area, Kerman, Iran. Shelled whole walnut (600 g) was homogenized in 1500 mL of methanol and kept at room temperature for 72 h and stirred daily (Chauhan et al. 2004). Then, the mixtures were filtered and organic layer was distilled under reduced pressure at 25 °C and freeze-dried. The crude extracts were stored at −20 °C until use (Joukar et al. 2013). The phenolic and flavonoid contents of this type of Persian walnut kernel (Gerdakaneh, genotype G1) have been assessed previously (Akbari et al. 2012). Its total phenolic content [gallic acid equivalents] was 115 mg/100 g and its flavonoid content [catechin equivalents] was 70 mg/100 g of kernel. Male Wistar rats weighing 250–300 g were allowed free access to standard laboratory rat chow and tap water and were housed under controlled temperature (21–23 °C) and 12 h light/dark cycle during experiment.

Experimental protocol

Animals were divided into seven groups and treated as follows:

Control (CTL) group: saline (1 mL/kg/d), vehicle for dexamethasone was injected subcutaneously (SC) daily for 11 d (T5–T15) and tap water (0.5 mL) by the gavage method for 15 d (T1–T15).

DX Group: dexamethasone (0.03 mg/kg; SC) (Thida et al. 2010) was injected daily from T5 to T15 and tap water (0.5 mL) by the gavage method for 15 d (T1–T15).

Walnut 100 (W100) group: rats received walnut extract 100 mg/kg (Qamar & Sultana 2011) by the gavage method for 15 d (T1–T15) and saline was injected SC daily for 11 d (T5–T15).

Walnut 200 (W200) group: rats were treated with walnut extract 200 mg/kg by the gavage method for 15 d (T1–T15) and saline was injected SC daily for 11 d (T5–T15).

W100 + DX group: 100 mg/kg of walnut extract was given by gavage for 15 d (T1–T15) and dexamethasone was injected SC daily for 11 d (T5 to T15).

W200 + DX group: 200 mg/kg of walnut extract was given by gavage for 15 d (T1 to T15) and dexamethasone was injected SC daily for 11 d (T5–T15).

Cap + DX group (positive control group): animals were treated with captopril 25 mg/kg/d (Olatunji & Soladoye 2008) by gavage for 15 d (T1–T15) and dexamethasone was injected SC daily for 11 d (T5–T15).

On the 16th day, the animals were anesthetized with sodium thiopental (50 mg/kg i.p.), and the trachea was cannulated for better spontaneously breathing throughout the experiment. A heparinized saline-filled (15 units/mL) cannula connected to a pressure transducer and PowerLab system was inserted into the left carotid artery to record heart rate (HR) and arterial BP (Joukar et al. 2012). BP and HR were recorded following recovery time from surgery (15 min). The mean arterial pressure (MAP) was calculated by ‘MAP = Ps + (Ps - Pd)/3 formula’, where Ps is the diastolic arterial pressure and Pd is the systolic arterial pressure. At the end of the experiment, the blood samples were taken to measure serum nitrite level. Then, the animals were sacrificed. Their hearts were removed and washed with cold saline. A piece of heart apex was dissected, weighed, and homogenized in 5 mL of 0.1 M Tris-HCl buffer (pH 7.4) in ice-cold condition. Thereafter, it was centrifuged by refrigerated centrifuge and the clear supernatant solution was taken for biochemical analysis. The amount of total protein was measured using the Lowry et al. (1951) method. Malondialdehyde (MDA) levels, an index of lipid peroxidation, which produced by oxidative elements activation, were estimated by concentration of thiobarbituric acid reactive substances (TBARS) in heart tissue (Ohkawa et al. 1979). The GPX in the heart tissue was determined using the Randox assay kit according to the manufacturer’s protocol (Ghorbani Baravati et al. 2015). Blood samples were centrifuged at 5000 g for 10 min for serum separation. Serum nitrite concentrations, the main metabolite of NO, were measured by Griess reaction method using available reagents and kit (Promega Co, Fitchburg, WI) with a detection limit of 2.5 μmol (Barmaki & Khazaei 2015).

Results

Blood pressure and heart rate

Administration of 200 mg/kg of walnut extract was associated with non-significant reduction of BP compared to CTL group. Taking dexamethasone for 11 d resulted in an increase in arterial BP in such a way that the diastolic pressure in DX group was significantly higher than CTL and W100 groups (p < 0.05). In addition, the MAP, systolic and diastolic pressures were significantly lower in W200 group than DX group (p < 0.01) (Figure 1). Co-administration of walnut and dexamethasone prevented the hypertensive effect of dexamethasone, so that the BP in W100 + DX and W200 + DX groups had no significant difference with CTL group. Moreover, in the presence of dexamethasone, the attenuating effect of 200 mg/kg of walnut extract on diastolic BP was similar to the captopril, a potent angiotensin-converting enzyme inhibitor and antihypertensive drug (Figure 1). Walnut and dexamethasone individually or together did not have significant effect on HR of animals (Figure 2).

Biochemical findings

The values of GPX as an enzymatic antioxidant indicator did not show significant difference in W100 and W200 groups in comparison with CTL group. This parameter was significantly lower in animal group that received dexamethasone alone compared with CTL, W100 (p < 0.05) and W200 groups (p < 0.01). Walnut therapy reversed the negative effect of dexamethasone on GPX level of heart tissue so that there was no significant difference
among W100, W200, DX, W100 and W200 groups. Captopril also helped to preserve this factor and prevented the significant reduction of this parameter in Cap+DX group (Figure 3). Walnut consumption 200 mg/kg/d increased the level of MDA, a lipid peroxidation marker, in heart tissue (p < 0.05 vs. CTL and W100 group). Dexamethasone administration had no remarkable effect on MDA level of heart. However, combination of walnut and dexamethasone was associated with significant increase in MDA level when compared with DX or W100 groups (p < 0.05). The lowest value of MDA was observed in Cap+DX group (Figure 4). The ratio of MDA/GPX was higher in the DX group (p < 0.05, vs. CTL group) and was lower in the Cap+DX group (p < 0.01, vs. DX group). Both doses of walnut consumption attenuated the incremental effect of dexamethasone on MDA/GPX so that the value of this index did not show significant difference between W100 + DX and W200 + DX groups vs. CTL group (Figure 5). Walnut virtually non-significant but dose-dependently increased the serum NO level. This parameter was non-significantly lower in DX group compared with CTL group. In presence of dexamethasone, 200 mg/kg of walnut consumption significantly improved the serum NO level (p < 0.05) (Figure 6).

**Discussion**

The results of this study showed the preventive effect of walnut extract on dexamethasone-induced hypertension. In addition, in presence of dexamethasone, walnut extract improved the NO production and prevented the imbalance of redox system.

In agreement with our finding, in a human study, West et al. (2010) demonstrated that hypercholesterolemic subjects who consumed walnut and walnut oil diet for 6 weeks showed a significant reduction in diastolic BP and total peripheral resistance, both at rest and during stress. In other study, individuals at high-cardiovascular risk who improved their diet towards a traditional Mediterranean diet plus nut pattern showed significant reduction in BP (Fitó et al. 2007). In an animal study, tannic acid, one of the major components of walnut, reduced the BP in
experimental hypertensive rats without any effect in normotensive rats (Turgut Cosan et al. 2015). Walnuts contain small amounts of sodium and a significant amount of magnesium, calcium, potassium, fibre, antioxidants and unsaturated fatty acids (Gharibzahedi et al. 2014) and all of these components can affect BP (Myers & Champagne 2007). The cardiovascular protective effects of the polyunsaturated and monounsaturated fatty acids found in walnut are approved (Fitch et al. 2007; Berryman et al. 2013). These substances can reduce the thromboxane A2 and hence its vasoconstrictor effect and thereby reduce the BP (Berrougui et al. 2004). The walnuts also contain significant amounts of potassium, which by reducing the volume of extracellular fluid and modulation of renin-angiotensin system can induce smooth muscle cell relaxation and reduction of peripheral resistance and thereby decrease the BP (Treasure & Ploth 1983). Calcium is the other abundant mineral in walnut that can reduce the intracellular calcium by inhibition of parathormone and leads to BP reduction (Jorde et al. 2000). The imbalance between oxidant and antioxidant activity in favour to the oxidative stress can cause the development of cardiovascular disease. Increase of pro-oxidants production, such as superoxide anion hydrogen peroxide, reduction of nitric oxide (NO) synthesis and decrease of antioxidants bioavailability are the major factors associated with oxidative stress-induced endothelial injury and promotion of hypertension (Sinha & Dabla 2015). This study showed that dexamethasone reduced GPX and increased MDA/GPX ratio and redox imbalance. It also non-significantly decreased the NO production that appeared as the lower level of serum NO metabolites in DX group. The dexamethasone-induced oxidative damage and apoptosis are reported in previous studies (Sun et al. 2015; Yi et al. 2015). Therefore, the increase of oxidative stress and reduction of NO synthesis and hence endothelial injury are the plausible mechanisms for elevated BP in DX group. Our results also showed that these negative effects recovered by walnut extract along with promotion of NO production and redox balance. Several human studies have shown the beneficial effects of walnut consumption on endothelial function and improvement of endothelium-dependent vasodilation (Ros et al. 2004; Cortés et al. 2006; West et al. 2010). In a randomized, crossover, and controlled-feeding study Haddad et al. (2014) showed that walnut meal increased plasma γ-tocopherol, hydrophilic and lipophilic oxygen radical absorbance capacity, ferric reducing antioxidant
power and uric acid. On the other hand, walnut meal decreased the oxidized LDL when compared with refined control meal. The antioxidant and free radical scavenging activity of walnut can be attributed to its phenolic (flavonoid and non-flavonoid) contents (Negi et al. 2011; Akbari et al. 2012). It is confirmed the high-correlation coefficient between phenol content and radical scavenging activity of walnut (Akbari et al. 2012). In addition, walnut has a high content of L-arginine, the amino acid precursor of the endogenous vasodilator NO (Cooke et al. 1993; Ros 2009). Thus, a part of preventive effect of walnut on dexamethasone-induced hypertension can explain by its antioxidant and its endothelial protective effects and also improvement of endothelium-dependent vasodilation.

Conclusions

These findings reveal that similar to captopril; walnut kernel extract is able to prevent dexamethasone-induced hypertension in rat. A part of this beneficial effect apparently induced through higher NO production and antioxidant system protection. It should be considered that walnut is an edible nut while captopril is a chemical drug with well-known side effects. Although more studies are warranted to extend this finding to human, the emerging picture is that walnut or perhaps other nuts to be supplementary regimen in clinical management of patients undergoing long-term treatment with steroids.
