Abstract

Introduction: The aim of this study was to investigate long-term outcomes in terms of pain, quality of life (QoL), and gastrointestinal symptoms in women following colorectal surgery for deep endometriosis.

Material and methods: In this historical cohort, women who underwent surgical treatment for deep endometriosis either nerve-sparing full-thickness discoid resection (DR) or colorectal segmental resection (SR) between March 2011 and August 2016 were re-evaluated through telephone interviews about their long-term pain symptoms, subjective overall QoL as rated using a score from 0 (worst) to 10 (optimal), and gastrointestinal outcomes reflected by lower anterior resection syndrome (LARS) following a first postsurgical evaluation (visit 1) published previously and a long-term follow-up evaluation (visit 2).

Results: The median long-term follow-up time was 35.4 months at visit 1 and 86 months at visit 2. Of 134 patients, 77 were eligible for final analysis and 57 were lost to follow-up. Compared with presurgical values, QoL scores were significantly increased at both postsurgical evaluation visits in both the SR cohort (scores of 3, 8.5, and 10 at the presurgical visit, visit 1, and visit 2, respectively; p < 0.001) and the DR cohort (scores of 3, 9, and 10, respectively; p < 0.001). Pain scores for dysmenorrhea (SR group scores of 8, 2, and 2, respectively; p < 0.001; DR group scores of 9, 2, and 1, respectively; p < 0.001), dyspareunia (SR group scores of 4, 0, and 0, respectively; p < 0.001; DR group scores of 5, 0, and 1, respectively; DR group scores of 5, 0, and 1, respectively; p = 0.003), and dyschezia (SR group scores of 8, 2, and 2, respectively; p < 0.001; DR group scores of 9, 2, and 1, respectively; p < 0.001) significantly decreased after surgery and remained stable in both cohorts over the follow-up period. Minor and major LARS, reflecting gastrointestinal function, was observed in 6.5% and 8.1% of the SR group and in 13.3% and 6.7% of the DR group, respectively, at visit 1 and in 3.2% and 3.2% of the SR group and 0% and 0% of the DR group, respectively, at visit 2, without significant differences between the SR and DR groups.

Abbreviations: DE, deep endometriosis; DR, discoid resection; LARS, lower anterior resection syndrome; SR, segmental resection; QoL, quality of life.
1 | INTRODUCTION

Endometriosis predominantly affects women in their reproductive years and may impair quality of life (QoL) and fertility. Deep lesions are usually associated with more adverse pain and gastrointestinal outcomes.1–4 The optimal treatment modality for symptomatic deep endometriosis (DE) should improve QoL and preserve or improve fertility with low recurrence and complication rates. Several studies have demonstrated a significant decrease in pain symptoms in women following surgical treatment for colorectal DE.5–8 However, debate is ongoing about how far surgical radicality – reflected by either segmental colorectal resection (SR) or discoid resection (DR), i.e. partial resection of the rectal wall, including the DE lesion or so-called rectal shaving – is really warranted to achieve optimal surgical outcomes, including preservation of gastrointestinal function.9

SR is usually performed in symptomatic patients with extensive, partially occluding, and/or multifocal disease,10,11 which may render so-called conservative approaches, including DR or shaving procedure, inappropriate. However, several lines of evidence indicate that SR may confer higher complication rates, including anastomotic leakage and fistula formation, compared with rectal shaving,12,13 with grade III complication rates similar to those with DR.13,14 Long-term sequelae of full-thickness colorectal resection also include lower anterior resection syndrome (LARS), which has been shown to occur following both techniques, without significant advantages of one method over the other.14,15 Interestingly, SR may be associated with a higher incidence of de novo bowel symptoms such as constipation.16 Nevertheless, data on long-term pain and functional outcomes following colorectal surgery for DE are limited. To further elucidate the therapeutic effect of surgical treatment over time, we evaluated the long-term results of our previously published data for SR and DR17 in terms of pain symptoms, QoL, and LARS scores.

2 | MATERIAL AND METHODS

We conducted a retrospective comparative follow-up study on pain outcomes, QoL, and LARS scores among women who underwent surgery for colorectal DE by either nerve-sparing, full-thickness DR or SR at the Clinic Ottakring and Hospital of St John of God, Vienna, Austria, from March 2011 to August 2016. All patients enrolled in a previous analysis were eligible for follow-up. All surgical procedures were performed by one main gynecological surgeon (GH) in a multidisciplinary team setting consisting of four colorectal surgeons (BD, TB, FB, MD) and two urological surgeons. All procedures were initially performed laparoscopically under general anesthesia using four ports with single-shot intravenous antibiotic treatment 1 h before surgery. The surgical steps of each technique were previously defined in detail.17

2.1 | Patients and outcomes

Postoperative data were obtained via a telephone survey. The interviews were performed by one co-author (DD). Pain symptoms such as dysmenorrhea, dyspareunia, dyschezia, and dysuria were evaluated using a numerical 10-point analogue rating scale as used in the primary work. Patients rated QoL on a scale of 0–10, with 0 being the lowest and 10 the highest score possible. LARS scores were used to evaluate gastrointestinal function. This is a widely applied tool designed to establish a scoring system for postoperative bowel dysfunction in patients who have undergone a low anterior resection. It asks about five important items: incontinence for flatus, incontinence for liquid stools, frequency, clustering, and urgency.18 Scores range from 0 to 42, where 0–20 is interpreted as no LARS, 20–30 is minor LARS, and 30–42 is major LARS.

2.2 | Statistical analyses

No parameters except for age were distributed normally. In descriptive statistics, age was given as mean ± standard deviation, and the other parameters were given as median (25–75th percentile). For the quantitative data, we used Student’s t test to compare normally distributed parameters and the Mann–Whitney U test to compare non-normally distributed parameters. The chi-squared test was used to compare qualitative data between surgery groups. We used Friedman’s test and a post-hoc Wilcoxon signed-rank test to evaluate the differences in QoL and symptom scores for each surgery.

Conclusions: Colorectal surgery for deep endometriosis, either by DR or SR, provides stable and long-term pain relief with low rates of permanent gastrointestinal function impairment.

Key message

Colorectal surgery for deep endometriosis, either by discoid or segmental outcomes in terms of pain, quality of life, and gastrointestinal symptoms.
group during the follow-up periods. All statistical analyses were performed using SPSS 17 (SPSS Inc.) software. A p-value of <0.05 was considered statistically significant.

2.3 | Ethical approval

The study was approved by the local institutional review board at Hospital St John of God (Reference number 2102/2018) on January 12, 2021.

3 | RESULTS

Of 134 patients, 77 (57.5%) were included in the final analysis and 57 (42.5%) were lost to follow-up. In total, 15 of the 77 (19%) patients underwent DR and 62 (81%) underwent SR. The median follow-up interval at visit 1 was 35.4–36.5 (±21.9) months in the SR group and 34.3 (±24.3) months in the DR group as published in our first work. The median follow-up interval at long-term visit 2 was 86 (68–104) months for all patients, with a median follow-up period of 90 (range 70–100) months for both the SR and DR groups (Figure 1). Interestingly, dysuria had decreased after surgery at the first postsurgical visit in the SR group but did not significantly decrease after surgery at the first and second postsurgical visits in the DR group. Nine of the 62 patients in the SR group used oral contraceptives or levonorgestrel-releasing intrauterine devices, primarily for contraceptive reasons. Three (8%) patients underwent two subsequent surgical procedures for endometriosis in the SR cohort (p = 0.17). Two patients who primarily underwent DR underwent secondary SR resection because of recurrent rectal DE. Three of the 15 patients in the DR group and 10 of the 62 patients in the SR group used oral contraceptives or levonorgestrel-releasing intrauterine devices, primarily for contraceptive reasons.

As depicted in Table 2, QoL scores significantly increased and the symptom scores for dysmenorrhea, dyspareunia, and dyschezia significantly decreased at the first postsurgical visit (visit 1) and remained stable over the follow-up period at visit 2 in both the SR and DR groups (Figure 1). Interestingly, dysuria had decreased after surgery at the first postsurgical visit and had increased at the second postsurgical visit in the SR group but did not significantly decrease after surgery at the first and second postsurgical visits in the DR group. Nine of the 62 (14.5%) patients in the SR group and three of the 15 (20%) patients in the DR group underwent bladder resection for endometriosis. In the subgroup analysis of the patients who underwent bladder resection, there were no significant changes in dysuria scores between preoperative and postsurgical visit 1, between postsurgical visits 1 and 2, and between preoperative and postsurgical visit 2 in both groups.

We observed no differences between LARS scores over the follow-up period at visit 2 in either surgery group (p = 0.45 and p = 0.79, respectively) (Table 2). All patients who were eligible for long-term follow-up were asked whether they would repeat the surgery with all its consequences; 80% of those in the DR cohort and 96% of those in the SR group were in favor of surgery.

### Table 1 | Patient characteristics, demographic data, and intraoperative findings of women undergoing segmental and discoid resection for colorectal deep infiltrating endometriosis

|                          | Segmental resection (n = 62) | Discoid resection (n = 15) | p-value |

*p < 0.05 vs presurgical; **p < 0.05 vs postsurgical-1.

The present study demonstrates that colorectal surgery for DE either by SR or DR not only provides significant pain relief for all reported symptoms and increases QoL over 2 years after surgery but also confers stable improvements over a long-term period of up to 7 years. In addition, the prevalence of digestive complaints following colorectal surgery for DE, either by SR or DR, appears to be an efficient and long-term effective treatment for symptomatic patients. Meuleman et al. reported a recurrence rate of 4%–25% at 2 years follow-up. A recent review showed a complete improvement of 85%–95% at 2-year follow-up. In our study, 8% and 19.9% of patients exhibited recurrent symptoms in the DR and SR groups, respectively. However, no differences in QoL scores between the DR and SR groups were observed. It is important to highlight the occurrence of postoperative LARS, which support the observation of higher recurrence rates after DR. Dysmenorrhea and dyschezia, two symptoms reported in the DR group, were not more frequent after DR but may be explained by the migration of our patients. Additionally, a significant correlation was observed between dysmenorrhea and dyschezia, indicating no potential benefit of one technique over the other. Changes in QoL scores indicating a moderate increase of symptoms in patients undergoing SR may be attributable to factors unrelated to surgery or endometriosis.

CONCLUSION

The present study demonstrates that colorectal surgery for DE either by SR or DR not only provides significant pain relief for all reported symptoms and increases QoL over 2 years after surgery but also confers stable improvements over a long-term period of up to 7 years. In addition, the prevalence of digestive complaints following colorectal surgery for DE, either by SR or DR, appears to be an efficient and long-term effective treatment for symptomatic patients.
and may influence pain symptoms. However, this may be negligible because only three of the 15 patients in the DR group and ten of the 62 patients in the SR group used oral contraceptives or levonorgestrel intrauterine devices, primarily for contraceptive reasons. Furthermore, LARS symptoms must be interpreted with caution because LARS-like symptoms may be prevalent in up to 10% of the healthy general population. Finally, the retrospective nature of our study may cause a potential bias, and further prospective studies are needed in this field, including control groups. The strengths of our work include the long observation period: very few other publications have evaluated the long-term effects of colorectal surgery for DE. Furthermore, the final argument in favor of surgery in symptomatic patients, despite the risk of complications and sequelae, such as LARS or bowel stenosis, can be observed in our patients’ responses to the question as to whether they would choose to undergo their surgery again. In total, 80% in the DR cohort and 96% in the SR cohort confirmed that they would.

5 | CONCLUSION

Surgical treatment of DE confers improvement that later plateaus and remains stable, increasing QoL, with low rates of severe complications and sequelae such as LARS. Future prospective studies that include control groups are necessary to support these assumptions. Colorectal surgery for DE, either by DR or SR, provides stable and long-term pain relief with low rates of permanent gastrointestinal function impairment.
