DEM AZURE CRYSTALS AND THE SCHUR POSITIVITY OF CATALAN FUNCTIONS

JONAH BLASIAK, JENNIFER MORSE, AND ANNA PUN

Abstract. Catalan functions, the graded Euler characteristics of certain vector bundles on the flag variety, are a rich class of symmetric functions which include $k$-Schur functions and parabolic Hall-Littlewood polynomials. We prove that Catalan functions indexed by partition weight are the characters of $U_q(\widehat{\mathfrak{sl}_\ell})$-generalized Demazure crystals as studied by Lakshmibai-Littelmann-Magyar and Naoi. We obtain Schur positive formulas for these functions, settling conjectures of Chen-Haiman and Shimozono-Weyman. Our approach more generally gives key positive formulas for graded Euler characteristics of certain vector bundles on Schubert varieties by matching them to characters of generalized Demazure crystals.

1. Introduction

The Kostka-Foulkes polynomials $K_{\lambda\mu}(q)$ originated in the character theory of $GL_\ell(\mathbb{F}_q)$ and their study has since flourished. They express the modified Hall-Littlewood polynomials in the Schur basis of the ring of symmetric functions, $H_\mu(x; q) = \sum_\lambda K_{\lambda\mu}(q) s_\lambda(x)$, and are $q$-weight multiplicities defined via a $q$-analog of Kostant’s partition function $P$:

$$K_{\lambda\mu}(q) = \sum_{w \in S_\ell} \text{sgn}(w) P_q(w(\lambda + \rho) - (\mu + \rho)) \quad \text{for} \quad \prod_{\alpha \in \Delta^+} \frac{1}{(1 - qx^\alpha)} = \sum_{\gamma \in \mathbb{Z}^\ell} P_q(\gamma)x^\gamma.$$

The positivity property, $K_{\lambda\mu}(q) \in \mathbb{Z}_{\geq 0}[q]$, has deep geometric and combinatorial significance: $K_{\lambda\mu}(q)$ are affine Kazhdan-Lusztig polynomials [64, 65], give characters of cohomology rings of Springer fibers [29, 83], record the Brylinski filtration of weight spaces [14], and are sums over tableaux weighted by the Lascoux-Schützenberger charge statistic [58].

A broader framework has emerged over the last decades. Broer [13] and Shimozono-Weyman [81], in their study of nilpotent conjugacy class closures, replaced the set of all positive roots $\Delta^+$ by a parabolic subset—the roots $\Delta(\eta) \subset \Delta^+$ above a block diagonal matrix. Panyushev [73] and Chen-Haiman [15] went further, taking any one of Catalan many upper order ideals $\Psi \subset \Delta^+$. The associated symmetric Catalan functions, $H(\Psi; \mu)(x; q) = \sum_\lambda K^\Psi_{\lambda\mu}(q) s_\lambda(x)$, indexed by $\Psi$ and partition $\mu$, are graded Euler characteristics of vector bundles on the flag variety.

The broader scope deepened ties to Kazhdan-Lusztig theory, advanced by the discovery of LLT polynomials [56, 59, 40, 23], and inspired a generalization of Jing’s Hall-Littlewood...
vertex operators [82]. Catalan functions were connected to spaces of coinvariants of fusion products in the WZW theory [19, 20], \( k \)-Schur functions and Gromov-Witten invariants [10, 11, 50, 52], and affine crystals [60, 69, 77, 79]. Positivity remained a central theme; extending earlier work of Broer, Chen-Haiman posed

**Conjecture 1.1.** The Catalan functions \( H(\Psi; \mu) \) are Schur positive: \( K_{\lambda \mu}^\Psi(q) \in \mathbb{Z}_{\geq 0}[q] \).

The picture in the dominant rectangle case, when \( \Psi = \Delta(\eta) \) and \( \mu \) is constant on parabolic blocks, is beautifully complete. These Catalan functions were equated with characters of \( U_q(\widehat{\mathfrak{sl}}_\ell) \)-Demazure crystals [79], and Schur positive formulas were established using Kirillov-Reshetikhin (KR) crystals [77, 78] and rigged configurations [39]. The view of Catalan functions as Euler characteristics ties their positivity to a conjecture on higher cohomology vanishing, first posed by Broer in the parabolic case and later extended by Chen-Haiman to arbitrary \( \Psi \) and partition \( \mu \); it was settled by Broer [13] in the dominant rectangle case.

The cohomology of vector bundles associated to Catalan functions, particularly for \( \Psi = \Delta^+ \), has been extensively studied [12, 13, 14, 25, 27, 43, 68, 73]. Hague [25] extended Broer’s cohomology vanishing result to some other classes of weights in the parabolic case, using Grauert-Riemenschneider vanishing and Frobenius splitting results of Mehta and van der Kallen [68]. Panyushev [73] established higher cohomology vanishing for a large subclass of Catalan functions; it includes the case \( \mu \) is strictly decreasing and \( \Psi \) arbitrary. Nonetheless, for arbitrary partitions \( \mu \), the vanishing conjecture remains open even for parabolic \( \Psi \).

The gold standard is to settle Conjecture 1.1 with a manifestly positive formula. Many attempts to extend the Lascoux-Schützenberger charge formula for Kostka-Foulkes polynomials were made. Shimozono-Weyman [81] conjectured such a formula for the parabolic Catalan functions \( H(\Delta(\eta); \mu) \), hinging on an intricate tableau procedure called katabolism. Soon after, katabolism led to the origin of \( k \)-Schur functions [49], and more recently, Chen-Haiman [15] proposed a variant of katabolism to solve Conjecture 1.1 completely. However, katabolism offered no traction for proofs.

We are now able to paint the picture in its entirety by moving to a larger framework of tame nonsymmetric Catalan functions \( H(\Psi; \mu; w) \), depending on an additional input \( w \in S_\ell \); they are Euler characteristics of vector bundles on Schubert varieties and specialize to Catalan functions when \( w = w_0 \). Our findings include

1. **Tame nonsymmetric Catalan functions are characters of \( U_q(\widehat{\mathfrak{sl}}_\ell) \)-generalized Demazure crystals**, subsets of \( B(\Lambda^1) \otimes \cdots \otimes B(\Lambda^p) \) of the form \( F_{\lambda_1} \cdots \otimes u_\Lambda \), where \( B(\Lambda^i) \) is a highest weight crystal, \( w_i = s_{j_1} \cdots s_{j_k} \) lies in the affine symmetric group \( \widehat{S}_\ell \), and \( \mathcal{F}_{\lambda_1}(S) = \bigcup_{b \in S; a_1, \ldots, a_p \geq 0} f_{j_1}^{a_1} \cdots f_{j_k}^{a_k} b \). Lakshmibai-Littelmann-Magyar [45] introduced these crystals in their study of Bott-Samelson varieties.

2. **Tame nonsymmetric Catalan functions are key positive**, implying and generalizing Conjecture 1.1. By the powerful theory of Demazure crystals [32, 35, 45, 63], \( U_q(\widehat{\mathfrak{sl}}_\ell) \)-generalized Demazure crystals restrict to disjoint unions of \( U_q(\widehat{\mathfrak{sl}}_\ell) \)-Demazure crystals, implying that their characters are key positive.

3. **Positive combinatorial formulas for the key coefficients of (2)**. We draw on techniques of Naoi [70] to match generalized Demazure crystals with a family of DARK crystals,
Demazure-like subsets of tensor products of KR crystals. Explicit katabolism combinatorics arises naturally by unraveling the $F_{w_i}$ operators on the DARK side.

(4) A katabolism tableau formula for Catalan functions. In the parabolic case, it agrees with and settles the Shimozono-Weyman conjecture.

(5) A conjectural module-theoretic strengthening of (2), generalizing the earlier higher cohomology vanishing conjectures of Broer and Chen-Haiman.

(6) The $t = 0$ nonsymmetric Macdonald polynomials $E_\alpha(x; q, 0)$ are tame nonsymmetric Catalan functions. Dating back to Sanderson [76], the $E_\alpha(x; q, 0)$ are characters of certain $U_q(\hat{s}_\ell)$-Demazure crystals. This topic has recently regained popularity [1, 2, 4, 5, 6, 61, 62, 72], and in particular Assaf-Gonzalez [5, 6] gave a key positive formula for $E_\alpha(x; q, 0)$. Our results yield a different key positive formula, which generalizes Lascoux’s tableau formula for cocharge Kostka-Foulkes polynomials [53].

2. Main results

The basic approach of [11] is to open the door to powerful inductive techniques by realizing $k$-Schur functions as a subclass of (symmetric) Catalan functions. In a similar spirit, our inductive approach here depends crucially on viewing the Catalan functions as a subclass of a larger family of nonsymmetric Catalan functions.

Nonsymmetric Catalan functions are Euler characteristics of vector bundles on Schubert varieties and can be defined by a Demazure operator formula. Fix $\ell \in \mathbb{Z}_{\geq 0}$. The symmetric group $S_\ell$ acts on $\mathbb{Z}[q][x] = \mathbb{Z}[q][x_1, \ldots, x_\ell]$ by permuting the $x_i$; let $s_i \in S_\ell$ denote the simple transposition which swaps $i$ and $i + 1$. Let $\mathcal{H}_\ell$ denote the 0-Hecke monoid of $S_\ell$ with generators $s_1, \ldots, s_{\ell-1}$. It is obtained from $S_\ell$ by replacing the relations $s_i^2 = id$ with $s_i^2 = s_i$. For $i \in [\ell - 1] := \{1, 2, \ldots, \ell - 1\}$, the Demazure operator $\pi_i$ is the linear operator on $\mathbb{Z}[q][x]$ defined by

$$\pi_i(f) = \frac{x_i f - x_{i+1}s_i(f)}{x_i - x_{i+1}}. \quad (2.1)$$

More generally, for any $w \in \mathcal{H}_\ell$, let $w = s_i s_{i_2} \cdots s_{i_m}$ and define the associated Demazure operator by $\pi_w := \pi_{i_1} \pi_{i_2} \cdots \pi_{i_m}$; this is well defined as the $\pi_i$ satisfy the 0-Hecke relations.

A root ideal is an upper order ideal of the poset $\Delta^+ = \Delta^+_\ell := \{(i, j) \mid 1 \leq i < j \leq \ell\}$ with partial order given by $(a, b) \leq (c, d)$ when $a \geq c$ and $b \leq d$. A labeled root ideal of length $\ell$ is a triple $(\Psi, \gamma, w)$ consisting of a root ideal $\Psi \subset \Delta^+_\ell$, a weight $\gamma \in \mathbb{Z}^\ell$, and $w \in \mathcal{H}_\ell$.

**Definition 2.1.** The nonsymmetric Catalan function associated to the labeled root ideal $(\Psi, \gamma, w)$ of length $\ell$ is

$$H(\Psi; \gamma; w)(x; q) := \pi_w \left( \text{poly} \left( \prod_{(i, j) \in \Psi} (1 - qx_i/x_j)^{-1} x^\gamma \right) \right) \in \mathbb{Z}[q][x], \quad (2.2)$$

where poly denotes the polynomial truncation operator, defined by its action on key polynomials: $\text{poly}(\kappa_\alpha) = \kappa_\alpha$ for $\alpha \in \mathbb{Z}^\ell_{\geq 0}$ and $\text{poly}(\kappa_\alpha) = 0$ for $\alpha \in \mathbb{Z}^\ell \setminus \mathbb{Z}^\ell_{\geq 0}$ (see §5).

In the case $w = w_0$, the longest element in $\mathcal{H}_\ell$, we recover the (symmetric) Catalan functions studied in [10, 11, 15, 73].
2.1. The rotation theorem. For a root ideal $\Psi \subset \Delta^+_\ell$, define the tuple $\mathbf{n}(\Psi) = (\mathbf{n}(\Psi)_1, \ldots, \mathbf{n}(\Psi)_{\ell-1}) \in [\ell]^{\ell-1}$ by

\[ \mathbf{n}(\Psi)_i := \left| \{ j \in \{ i, i+1, \ldots, \ell \} : (i, j) \notin \Psi \} \right|. \]  

(2.3)

**Definition 2.2.** A labeled root ideal $(\Psi, \gamma, w)$ of length $\ell$ is tame if the right descent set $\{ i \in [\ell - 1] \mid ws_i = w \}$ of $w$ contains $\mathbf{n}(\Psi)_1 + 1, \mathbf{n}(\Psi)_1 + 2, \ldots, \ell - 1$; informally, this means that $\pi_w$ symmetrizes the columns which intersect $\Psi$. We also say that the associated nonsymmetric Catalan function is tame.

Define the $\mathbb{Z}[q]$-algebra homomorphism $\Phi$ of $\mathbb{Z}[q][x]$ by

\[ \Phi(x_i) = x_{i+1} \text{ for } i \in [\ell - 1], \quad \Phi(x_\ell) = qx_1. \]  

(2.4)

A crucial finding of this paper is the following operator formula for tame nonsymmetric Catalan functions.

**Theorem 2.3.** For any tame labeled root ideal $(\Psi, \gamma, w)$ with $\gamma \in \mathbb{Z}_\ell^\geq$,

\[ H(\Psi; \gamma; w) = \pi_w x_1^{\pi_1(\Psi)} \Phi \pi_{s(n_1)} x_1^{\pi_2(\Psi)} \Phi \pi_{s(n_2)} x_1^{\pi_3(\Psi)} \cdots \Phi \pi_{s(n_{\ell-1})} x_1^{\pi_\ell(\Psi)}, \]  

(2.5)

where $(n_1, \ldots, n_{\ell-1}) = \mathbf{n}(\Psi)$ and $s(d) := s_{d-1} s_{d-2} \cdots s_d \in \mathcal{H}_\ell$ for $d \in [\ell]$.

Its proof requires an in-depth understanding of polynomial truncation and is given in Section 5. The operator $\Phi$ arises in a recurrence for nonsymmetric Macdonald polynomials, and we will see in Section 8 that its appearance here is no coincidence.

2.2. Affine generalized Demazure crystals and key positivity. Theorem 2.3 allows us to connect tame nonsymmetric Catalan functions with affine Demazure crystals. We describe this connection here, but defer a thorough treatment of crystals to Section 4.

Let $U_q(\mathfrak{g})$ be the quantized enveloping algebra of a symmetrizable Kac-Moody Lie algebra $\mathfrak{g}$ (as in [37]). Among the data specifying a $U_q(\mathfrak{g})$-crystal $B$ are maps $\tilde{f}_i : B \cup \{0\} \rightarrow B \cup \{0\}$ for $i$ ranging over the Dynkin node set $I$. For a subset $S$ of $B$ and $i \in I$, define

\[ \mathcal{F}_i S := \{ \tilde{f}_i^m b \mid b \in S, m \geq 0 \} \setminus \{0\} \subset B. \]

For a dominant integral weight $\Lambda \in P^+$, let $B(\Lambda)$ denote the highest weight $U_q(\mathfrak{g})$-crystal of highest weight $\Lambda$ and $u_\Lambda$ its highest weight element.

**Definition 2.4.** A $U_q(\mathfrak{g})$-Demazure crystal is a subset of a highest weight $U_q(\mathfrak{g})$-crystal $B(\Lambda)$ of the form $\mathcal{F}_{i_1} \cdots \mathcal{F}_{i_k} \{u_\Lambda\}$.

Now specialize to $\mathfrak{g} = \widehat{\mathfrak{sl}_\ell}$, our focus here. The associated data includes Dynkin nodes $I = \mathbb{Z}/\ell \mathbb{Z} = \{ 0, 1, \ldots, \ell - 1 \}$, fundamental weights $\{ \Lambda_i \mid i \in I \}$, weight lattice $P = \sum_{i \in I} \mathbb{Z} \Lambda_i \oplus \mathbb{Z} \delta / \ell \mathbb{Z}$, and dominant weights $P^+ = \sum_{i \in I} \mathbb{Z}_{\geq 0} \Lambda_i + \mathbb{Z} \delta / \ell \mathbb{Z} \subset P$. Let $\tau$ denote the Dynkin diagram automorphism $I \rightarrow I$, $i \mapsto i + 1$. Let $\mathcal{S}_\ell$ denote the extended affine symmetric group and $\mathcal{H}_\ell$ its 0-Hecke monoid. The generators of $\mathcal{H}_\ell$ are denoted $\tau$ and $s_i$ ($i \in I$), and relations include $\tau s_i \tau^{-1} = s_{\tau(i)} = s_{i+1}$, braid relations, and $s_i^2 = s_i$.

**Definition 2.5.** Let $\mathcal{D}(\widehat{\mathfrak{sl}_\ell})$ be the set of all subsets $S \subset B$ such that $B$ is a tensor product of highest weight $U_q(\widehat{\mathfrak{sl}_\ell})$-crystals and the image of $S$ under $B \xrightarrow{\pi}$ is a disjoint union of $U_q(\widehat{\mathfrak{sl}_\ell})$-Demazure crystals. Here, $M$ is a multiset of elements of $P^+$. 

For $\Lambda \in P^+$, define the bijection of sets $F_\tau: B(\Lambda) \to B(\tau(\Lambda))$ by \( f_d \mapsto f_d \mu \), for any $j_1, \ldots, j_k \in I$ and $d_i \in \mathbb{Z}_{\geq 0}$; we also denote by $F_\tau$ the bijection $B(\Lambda^1) \otimes \cdots \otimes B(\Lambda^p) \xrightarrow{\tau_1 \otimes \cdots \otimes \tau_p} B(\tau(\Lambda^1)) \otimes \cdots \otimes B(\tau(\Lambda^p))$, for $\Lambda^1, \ldots, \Lambda^p \in P^+$. We can regard $F_\tau(i)$ and $F_\tau$ as operators on $D(\mathfrak{sl}_\ell)$ and as such they satisfy the relations of $\mathcal{H}_\ell$ (by [35, 70]—see §4.7). This yields a well-defined operator $F_w: D(\mathfrak{sl}_\ell) \to D(\mathfrak{sl}_\ell)$ for any $w \in \mathcal{H}_\ell$. From Corollary 2.7 and Kashiwara’s results on Demazure crystals [35], one readily obtains a Demazure operator formula for the character of $\text{AGD}(\mu)$—see §4.7. This argument is essentially due to [45], with the extended affine setup treated carefully in [70].

**Theorem 2.6** (Combinatorial Excellent Filtration [32, 45]). For any $\Lambda^1, \Lambda^2 \in P^+$ and $w \in \mathcal{H}_\ell$, $B_w(\Lambda^2) \otimes u_{\Lambda^1}$ is isomorphic to a disjoint union of $U_q(\mathfrak{sl}_\ell)$-Demazure crystals.

A $U_q(\mathfrak{sl}_\ell)$-generalized Demazure crystal is a subset of a tensor product of highest weight crystals of the form $F_{w_1}(F_{w_2}(\cdots F_{w_{p-1}}(F_{w_p}(u_{\Lambda^p}) \otimes u_{\Lambda^{p-1}}) \otimes \cdots \otimes u_{\Lambda^2}) \otimes u_{\Lambda^1})$ for some $\Lambda^1, \ldots, \Lambda^p \in P^+$ and $w_1, \ldots, w_p \in \mathcal{H}_\ell$. Theorem 2.6 and the well-definedness of $F_w$ on $D(\mathfrak{sl}_\ell)$ show that these are well-defined and yield the following corollary (this argument is essentially due to [45], with the extended affine setup treated carefully in [70]).

**Corollary 2.7.** Any $U_q(\mathfrak{sl}_\ell)$-generalized Demazure crystal is isomorphic to a disjoint union of $U_q(\mathfrak{sl}_\ell)$-Demazure crystals.

Our focus is on the following subclass of $U_q(\mathfrak{sl}_\ell)$-generalized Demazure crystals: for $w = (w_1, w_2, \ldots, w_p) \in (\mathcal{H}_\ell)^p$ and a partition $\mu = (\mu_1 \geq \cdots \geq \mu_p \geq 0)$, define the associated affine generalized Demazure (AGD) crystal by

$$
\text{AGD}(\mu; w) := F_{w_1}(F_{w_2}((\cdots F_{w_{p-1}}(F_{w_p}(u_{\mu^p}) \otimes u_{\mu^{p-1}}) \otimes \cdots \otimes u_{\mu^2}) \otimes u_{\mu^1})) 
\subseteq B(\mu^p) \otimes \cdots \otimes B(\mu^1),
$$

(2.6)

where $\mu^i = \mu_i - \mu_{i+1}$, with $\mu_{p+1} := 0$.

Let $\mathbb{Z}[P]$ denote the group ring of $P$ with $\mathbb{Z}$-basis $\{e^{\lambda}\}_{\lambda \in P}$. The character of a $U_q(\mathfrak{sl}_\ell)$-crystal $G$ is $\text{char}(G) = \sum_{g \in G} e^{\text{wt}(g)} \in \mathbb{Z}[P]$. Define the ring homomorphism $\zeta$ by

$$
\zeta: \mathbb{Z}[q][x] \to \mathbb{Z}[P], \quad x_i \mapsto e^{\Lambda_i-\Lambda_{i-1}+\ell+1-2\ell \delta}, \quad q \mapsto e^{-\delta}.
$$

(2.7)

Let $s(\Psi)$ be as in (2.3) and $s(d) = s_{\ell-1}s_{\ell-2} \cdots s_d$. For a root ideal $\Psi$, set

$$
s(\Psi) := (s(n(\Psi)_1), \ldots, s(n(\Psi)_{\ell-1})) \in (\mathcal{H}_\ell)^{\ell-1}.
$$

(2.8)

**Theorem 2.8.** Tame nonsymmetric Catalan functions of partition weight are characters of AGD crystals: for any tame labeled root ideal $(\Psi, \mu, w)$ of length $\ell$ with partition $\mu$,

$$
\zeta(H(\Psi; \mu; w)) = e^{-\mu_1 \lambda_0 + n(\mu) \delta} \text{char}(\text{AGD}(\mu; (w, s(\Psi))))
$$

(2.9)

where $n(\mu) = \frac{|\mu|}{2\ell} - \frac{1}{\ell} \sum_{i=1}^{\ell} (i-1) \mu_i$.

**Proof sketch.** From Corollary 2.7 and Kashiwara’s results on Demazure crystals [35], one readily obtains a Demazure operator formula for the character of $\text{AGD}(\mu; (w, s(\Psi)))$, which is not difficult to connect to the rotation Theorem 2.3. □
It can further be shown that the $U_q(\mathfrak{sl}_e)$-restriction of a $U_q(\mathfrak{sl}_e)$-Demazure crystal is isomorphic to a disjoint union of $U_q(\mathfrak{sl}_e)$-Demazure crystals (Theorem 4.1). Combining this with Corollary 2.7 and Theorem 2.8 proves that

**Corollary 2.9.** The tame nonsymmetric Catalan functions are key positive.

More detailed versions of Theorem 2.8 and Corollary 2.9—Theorem 7.5 and Corollary 7.13—are stated and proved in Section 7. They include explicit positive formulas for the key expansions.

### 2.3. DARK crystals

To extract key positive formulas from Theorem 2.8, we use a technique of Naoi [70] to match generalized Demazure crystals with subsets of tensor products of KR crystals, termed DARK crystals; the latter appears to have simpler combinatorics and, remarkably, exactly matches the katabolism combinatorics conjectured in [81].

Let $B^{1,s}$ denote the single row KR crystal; it is a seminormal crystal for the subalgebra $U_q'(\mathfrak{sl}_e) \subset U_q(\mathfrak{sl}_e)$ (see §4.4). Its elements are labeled by weakly increasing words of length $s$ in the alphabet $[\ell]$. For $\mu = (\mu_1 \geq \cdots \geq \mu_p \geq 0)$, set $B^\mu = B^{1,\mu_p} \otimes \cdots \otimes B^{1,\mu_1}$.

**Definition 2.10.** The Kirillov-Reshetikhin affine Demazure (DARK) crystal associated to $\mu = (\mu_1 \geq \cdots \geq \mu_p \geq 0)$ and $w = (w_1, \ldots, w_p) \in (\mathcal{H}_k)^p$, is the following subset of $B^\mu$:

$$B^{\mu,w} := \mathcal{F}_{w_1}(\mathcal{F}_{\tau} \mathcal{F}_{w_2}(\cdots \mathcal{F}_{\tau} \mathcal{F}_{w_p}(B_{\mu_1} \otimes B_{\mu_{p-1}}) \otimes B_{\mu_2}) \otimes B_{\mu_1}),$$

where $b_s \in B^{1,s}$ is the element labeled by the word $1^s$, $\mathcal{F}_{\tau} : B^{1,\mu_p} \otimes \cdots \otimes B^{1,\mu_j} \to B^{1,\mu_p} \otimes \cdots \otimes B^{1,\mu_j}$ is given by adding 1 (mod $\ell$) to each letter and then sorting each tensor factor to be weakly increasing (see Proposition 6.12), and $\mathcal{F}_{w_i} = \mathcal{F}_{j_1} \cdots \mathcal{F}_{j_k}$ for any chosen expression $w_i = s_{j_i} \cdots s_{j_k}$ ($i \in [p]$); the right side of (2.10) does not depend on these choices by [8, Theorem 3.7]. See §2.7 for examples.

The following modification of [70, Proposition 5.16] allows us to port results in crystal theory from AGD to DARK crystals.

**Theorem 2.11** ([8, Corollary 3.11]). Let $w, \mu, \mu^i$ be as in (2.6). There is a strict embedding of $U_q'('\mathfrak{sl}_e')$-seminormal crystals (see §4.1)

$$\Theta_\mu : B^\mu \otimes B(\mu_1 \Lambda_0) \hookrightarrow B(\mu^p \Lambda_p) \otimes \cdots \otimes B(\mu^1 \Lambda_1);$$

it is an isomorphism from the domain onto a disjoint union of connected components of the codomain. And under this map, $\Theta_\mu(B^{\mu,w} \otimes u_{\mu_1,\Lambda_0}) = \text{AGD}(\mu; w)$. Here, the $B(s\Lambda_i)$ are regarded as $U_q'(\mathfrak{sl}_e)$-seminormal crystals by restriction—see §4.4.

**Remark 2.12.** This article makes important use of the $U_q'(\mathfrak{sl}_e)$-crystal structures of $B^\mu \otimes B(\mu_1 \Lambda_0)$ and $B(\mu^p \Lambda_p) \otimes \cdots \otimes B(\mu^1 \Lambda_1)$, but not of $B^\mu$—it does not seem to be the right object for the combinatorics of interest here. However, the $U_q(\mathfrak{sl}_e)$-restriction of $B^\mu$, being isomorphic to that of $B^\mu \otimes B(\mu_1 \Lambda_0)$, is of interest and will be frequently used.

### 2.4. Katabolism and Schur positive formulas

We establish the Schur positivity of Catalan functions in the strongest possible terms with a streamlined tableau formula. It arises naturally from DARK crystals by unraveling the $\mathcal{F}_{w_i}, \mathcal{F}_{\tau}$, and tensor operations in their construction (in the spirit of [45, 46]).
Given a weak composition \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \in \mathbb{Z}_{\geq 0}^\ell \), the diagram of \( \alpha \) consists of a left justified array of boxes with \( \alpha_i \) boxes in row \( i \) (rows are allowed to be empty). A tabloid \( T \) of shape \( \alpha \) is a filling of the diagram of \( \alpha \) with weakly increasing rows, drawn in English notation with rows labeled \( 1, 2, \ldots, \ell \) from the top down. Set \( \text{shape}(T) = \alpha \). The content of \( T \) is the vector \((c_1, \ldots, c_\ell)\), where \( c_i \) is the number of times letter \( i \) appears in \( T \).

Let \( \text{Tabloids}_\ell \) denote the set of tabloids of any shape \( \alpha \in \mathbb{Z}_{\geq 0}^\ell \), and \( \text{Tabloids}_\ell(\mu) \subset \text{Tabloids}_\ell \) the subset with fixed content \( \mu \). Let \( \text{SSYT}_\ell(\mu) \) denote the subset of \( \text{Tabloids}_\ell(\mu) \) which are tableaux, tabloids with partition shape and where entries strictly increase down columns. Given a tabloid \( T \), let \( T^i \) denote the \( i \)-th row of \( T \) and \( T[i,j] \) the subtabloid of \( T \) consisting of the rows in the interval \([i,j] := \{i, i+1, \ldots, j\}\); set \( T[\cdot] = T[1,\cdot] \).

**Definition 2.13** (Partial insertion). For \( T \in \text{Tabloids}_\ell \) such that \( T[i,\ell-1] \) is a tableau, define \( P_{i,\ell}(T) \in \text{Tabloids}_\ell \) to be the tabloid obtained by column inserting the \( \ell \)-th row of \( T \) into \( T[i,\ell-1] \) and leaving rows 1 through \( i-1 \) of \( T \) fixed. (There is a way to extend this definition to any tabloid \( T \) but this simpler version is all we need for the results of this section—see Definition 6.8 and Remark 6.16.)

**Example 2.14.** Let \( \ell = 5 \). We compute \( P_{2,5}(T) \) for the \( T \in \text{Tabloids}_5(4, 3, 3, 3, 2) \) below:

\[
T = \begin{bmatrix}
1 & 1 & 1 & 1 & 1 \\
2 & 2 & 2 & 2 & 2 \\
3 & 3 & 3 & 3 & 3 \\
4 & 4 & 4 & 4 & 4 \\
5 & 5 & 5 & 5 & 5
\end{bmatrix}
\]

\( \text{shape}(T) = (6, 2, 2, 0, 5) \)

\( \text{shape}(P_{2,5}(T)) = (6, 5, 2, 2, 0) \)

**Definition 2.15** (Katabolism). For \( T \in \text{Tabloids}_\ell \), define \( \text{kat}(T) \in \text{Tabloids}_\ell \) as follows: remove all 1’s from \( T \) and left justify rows, then remove the first (top) row and add it as the new \( \ell \)-th row, and finally subtract 1 from all letters.

Let \( n = (n_1, \ldots, n_{p-1}) \in [\ell]^{p-1} \) and \( \mu \in \mathbb{Z}_{\geq 0}^\ell \) for some \( p \in \mathbb{Z}_{>1} \). A tableau \( T \in \text{SSYT}_\ell(\mu) \) is \( n \)-katabolizable if, for all \( i \in [p-1] \), the tabloid \( P_{n_i,\ell} \circ \text{kat} \circ \cdots \circ P_{n_2,\ell} \circ \text{kat} \circ P_{n_1,\ell} \circ \text{kat}(T) \) has all its 1’s on the first row.

**Example 2.16.** For \( \ell = 5 \) and \( n = (3, 2, 2, 1) \), the tableau below (left) is \( n \)-katabolizable:

In contrast, the following tableau is not \( n \)-katabolizable:

The elements of \( \mathcal{B}^\mu \) are naturally labeled by biwords whose top word is \( \mu^{\ell p} \cdots 2^{\mu_2}1^{\mu_1} \) and whose bottom word is weakly increasing on the intervals with constant top word. Define the bijection \( \text{inv}: \mathcal{B}^\mu \xrightarrow{\cong} \text{Tabloids}_\ell(\mu) \) as follows: for all \( i \), the \( i \)-th row of \( \text{inv}(b) \) is obtained by sorting the letters above the \( i \)’s in the bottom word of \( b \in \mathcal{B}^\mu \). (This is essentially the well-known inverse map on biwords generalizing the inverse of a permutation—see §6.4.) Katabolism exactly characterizes the image of DARK crystals under \( \text{inv} \).
Theorem 2.17. For a partition $\mu$ and root ideal $\Psi$, the map $\text{inv}$ gives a bijection

$$\mathcal{B}_{\mu; (w_0, s(\Psi))}^{\text{inv}} \rightarrow \{ T \in \text{Tabloids}_\ell(\mu) \mid P(T) \text{ is } n(\Psi)-\text{katabolizable} \}$$

which takes content to shape. Here, $P(T)$ denotes the insertion tableau of the row reading word $T^\ell \cdots T^1$ of $T$.

We settle Conjecture 1.1 with a manifestly positive formula.

Theorem 2.18. For any root ideal $\Psi \subset \Delta^+_\ell$ and partition $\mu = (\mu_1 \geq \cdots \geq \mu_\ell \geq 0)$, the associated Catalan function has the following Schur positive expression:

$$H(\Psi; \mu; w_0) (x; q) = \sum_{\substack{U \in \text{SSYT}_\ell(\mu) \mid U \text{ is } n(\Psi)-\text{katabolizable}}} q^{\text{charge}(U)} s_{\text{shape}(U)} (x). \quad (2.11)$$

Proof sketch (details in §7.3). Combine Theorems 2.17, 2.8, and 2.11 and select the tabloids which are $\text{inv}$ of the $U_q(\mathfrak{sl}_\ell)$-highest weight elements of $\mathcal{B}_{\mu; (w_0, s(\Psi))}$.

See Example 7.14. When $\Psi = \Delta^+$, every $U \in \text{SSYT}_\ell(\mu)$ is $1$-katabolizable and this is the Lascoux-Schützenberger [58] charge formula for the modified Hall-Littlewood polynomial $H_\mu(x; q) = \sum_\lambda K_{\mu\lambda}(q)s_\lambda(x)$.

Theorem 2.18 resolves the Shimozono-Weyman conjecture [81, Conjecture 27] for the generalized Kostka polynomials $K_{\mu\lambda}(q)$. Indeed, Proposition 7.7 confirms that Shimozono-Weyman katabolizability agrees with $n(\Psi)$-katabolizability for the parabolic root ideal $\Psi = \Delta(\eta)$, defined for $\eta \in \mathbb{Z}_{\geq 0}^r$ by

$$\Delta(\eta) := \{ \alpha \in \Delta^+_\ell \text{ above the block diagonal with block sizes } \eta_1, \ldots, \eta_r \}. \quad (2.12)$$

For example, $\Delta(1, 3, 2)$.

This gives the first proof of positivity for the Catalan functions and generalized Kostka polynomials in the parabolic case.

Remark 2.19. Shimozono [78] and Schilling-Warnaar [77] give a positive formula for the dominant rectangle Catalan functions $H(\Delta(\eta); \mu; w_0)$ (i.e., $\mu = a_1^{\eta_1} \cdots a_r^{\eta_r}, a_1 \geq \cdots \geq a_r$) using tensor products of arbitrary KR crystals in type A. Included in Theorem 2.18 is a different formula addressing this case, using subsets of tensor products of single row KR crystals. Conjecture 10 of [40] proposes a map to reconcile these two different formulas.

We further obtain a positive combinatorial formula for the key expansion of any tame nonsymmetric Catalan function of partition weight by similar methods (Corollary 7.13).

2.5. Consequences for $t = 0$ nonsymmetric Macdonald polynomials. A deep theory of nonsymmetric Macdonald polynomials has developed over the last 30 years, beginning with the work of Opdam-Heckman [71], Macdonald [67], and Cherednik [16]. Our results apply to the type A nonsymmetric Macdonald polynomials at $t = 0$, $E_\alpha(x; q, 0)$, a nonsymmetric generalization of the modified Hall-Littlewood polynomials. They were connected to affine Demazure characters by Sanderson [76] and the subject of recent results and conjectures on key positivity [1, 2, 4, 5, 6]. The $t = 0$ nonsymmetric Macdonald
polynomials in other types have also received considerable attention [30, 61, 62, 72]. Our results yield the following.

**Theorem 2.20.** For any $\alpha \in \mathbb{Z}_\geq 0$, $E_\alpha(x; q, 0)$ is (1) the character of a $U_q(\widehat{sl}_\ell)$-Demazure crystal, and (2) key positive with key expansion

$$E_\alpha(x; q, 0) = \sum q^{\sum_i (\alpha_i^2) - \text{charge}(P(T))} S_{\text{shape}(T)}(x),$$

(2.13)

where the sum is over tabloids $T$ satisfying the katabolizability conditions in Corollary 8.4/Definition 7.10. Further, up to a specialization $x_\ell+1 = \cdots = x_m = 0$ when $m = |\alpha| > \ell$, $E_\alpha(x; q, 0)$ is (3) a tame nonsymmetric Catalan function, and (4) the Euler characteristic of a vector bundle on a Schubert variety.

**Proof.** Statement (1) is due to Sanderson [76], and we also recover it as a special case of our character formula (7.8) for AGD crystals (see Theorem 8.3). Statement (2) is proved in Corollary 8.4, (3) in Theorem 8.11, and (4) follows from (3) and Theorem 3.2. □

The formula (2.13) generalizes Lascoux’s formula for cocharge Kostka-Foulkes polynomials [53], answering a call put out in [2, Conjecture 15], [55, p. 267-268] for a description of the key coefficients of $E_\alpha(x; q, 0)$ in this style. Assaf-Gonzalez [5, 6] studied the problem from a different point of view and realized the coefficients in terms of crystals on nonattacking fillings with no coinversion triples (objects defined in [24]). See also Remark 8.6.

**2.6. Consequences for $k$-Schur functions.** The $k$-Schur functions are a family of symmetric functions which arose in the study of Macdonald polynomials [49] and were subsequently connected to Gromov-Witten invariants and affine Schubert calculus [51, 52, 47]. For $\mu = (k \geq \mu_1 \geq \cdots \geq \mu_\ell \geq 0)$, define the $k$-Schur Catalan function by $s^{(k)}(x; q)$ := $H(\Delta^k(\mu); \mu; w_0)(x; q)$, where the root ideal $\Delta^k(\mu)$ is determined by $n(\Delta^k(\mu))_i = \min\{k - \mu_i + 1, \ell - i + 1\}$ for all $i \in [\ell]$. Building off of [47, 48, 51], it was established [11] that the $q = 1$ specializations $\{s^{(k)}(x; 1)\}$ represent Schubert classes in the homology of the affine Grassmannian $\text{Gr}_{\text{SL}_{k+1}}$.

A combinatorial formula for the Schur expansion of $s^{(k)}(x)$ was given in [11] in terms of chains in Bruhat order on the affine symmetric group $\widehat{S}_{k+1}$ and the spin statistic. Theorem 2.18 yields a very different formula:

**Corollary 2.21.** The $k$-Schur function $s^{(k)}(x)$ has the following Schur positive expansion:

$$s^{(k)}(x) = \sum_{T \in \text{SSYT}_{\ell}(\mu)} q^{\text{charge}(T)} S_{\text{shape}(T)}. \quad (2.14)$$

Namely, $T$ occurs in the sum as follows: remove the $\mu_1$ 1’s from the first row of $T$ and column insert the remainder of row 1 into rows larger than $\min\{k - \mu_1, \ell - 1\}$; remove $\mu_2$ 2’s from first row and column insert its remainder into rows larger than $\min\{k - \mu_2, \ell - 2\}$; continue until reaching an $i$ such that there are not $\mu_i$ 1’s in the first row; $T$ survives if no such $i$ occurs.

Example 7.14 illustrates (2.14) for $s^{(3)}_{22211}$. This formula has the same spirit as the original definition of $k$-Schur functions [49], which expressed them in terms of sets of
tableaux called super atoms $\Lambda^{(k)}_\mu$, constructed using Shimozono-Weyman katabolism and crystal reflection operators.

**Conjecture 2.22.** The set of tableaux appearing in (2.14) is equal to the super atom $\Lambda^{(k)}_\mu$.

### 2.7. Examples

Here, we provide running examples for reference throughout the article. Similar examples are also given in Figure 5 on the last page.

Figure 1 (right) depicts the DARK crystal $B^{\mu,w}$ for $\ell = 3, \mu = (2, 1, 1), w = (id, s_2 s_1, s_2 s_1)$; it can be constructed step by step using the $\mathcal{F}_i, \mathcal{F}_r$, and tensor operations as illustrated.

The first two lines give two different names for each DARK crystal. The connected components of solid edges decompose them into $U_q(\mathfrak{sl}_\ell)$-Demazure crystals, each of which
has character equal to a key polynomial; the key expansions of their charge weighted characters (see §7) are given in the third to last line, written so that reading left to right gives the components top to bottom, e.g., \{3211\} has character \(\kappa_{211} = x_1^2x_2x_3\). By Corollary 7.13, these characters are tame nonsymmetric Catalan functions (second to last line), though this requires rewriting the DARK crystals appropriately (last line), e.g., \(\mathcal{F}_{s_1}(\mathcal{F}_\tau \mathcal{F}_{s_{2s_1}}(b_1) \otimes b_1) = \mathcal{F}_{s_{1s_2}}(\mathcal{F}_\tau \mathcal{F}_{s_{2s_1}}(b_0) \otimes b_1) = B^{(1,1,0);(s_{1s_2},s_2s_1,s_{2s_1})}\). Here, \(b_s\) denotes the element of \(B_1\), labeled by \(1\), with \(b_0\) the empty word (see §6.1).

The dashed arrows are the \(\tilde{f}_i\)-edges of \(B^{\mu,w} \otimes u_{2A_0}\) (technically this is just a subset of the \(U'_q(\widehat{\mathfrak{sl}_2})\)-seminormal crystal \(B^{\mu} \otimes B(2A_0)\) but we often think of it as coming with the edges \(\tilde{f}_i, \tilde{e}_i\) \((i \in I)\) which have both ends in the subset). By Theorem 2.11, \(AGD(\mu; \mathbf{w}) = \Theta_\mu(B^{\mu,w} \otimes u_{2A_0})\), which is isomorphic to a disjoint union of \(U_q(\widehat{\mathfrak{sl}_2})\)-Demazure crystals; the corresponding decomposition of \(B^{\mu,w}\) is given by the components of dashed and solid edges (in the rightmost crystal). Here there are two such components, so \(AGD(\mu; \mathbf{w})\) is not a single \(U_q(\widehat{\mathfrak{sl}_2})\)-Demazure crystal; this demonstrates a fundamental difference between this work and earlier work [44, 76, 79] relating generalizations of Kostka-Foulkes polynomials to Demazure crystals, where only single \(U_q(\widehat{\mathfrak{sl}_2})\)-Demazure crystals were used.

Figure 2 depicts the tabloids obtained by applying \text{inv} to the rightmost two DARK crystals in Figure 1. By Theorem 6.20 (the full version of Theorem 2.17), the tabloids on the right are also the \(T \in \text{Tabloids}_{s_4}(211)\) which are \(\mathbf{w}\)-katabolizable in the sense of Definition 6.14; the ones on the left are the \(T \in \text{Tabloids}_{s_4}(11)\) which are \((s_{1s_2},s_2s_1)\)-katabolizable. The bold tabloids, by reading off their shapes and charges, give the rightmost two key expansions in Figure 1; this will be explained in Corollary 7.13.

3. Higher cohomology vanishing and nonsymmetric Catalan functions

This section uses notation in §1, (2.1)–(2.2), and Definition 5.1, but is otherwise notionally independent from the remainder of the paper.

Let \(G = GL_\ell(\mathbb{C})\) and \(B \subset G\) the standard upper triangular Borel subgroup. For \(w \in \mathcal{S}_\ell\), let \(X_w = B \cdot wB \subset G/B\) denote the Schubert variety. Given a \(B\)-module \(N\), let \(G \times_B N\) denote the homogeneous \(G\)-vector bundle on \(G/B\) with fiber \(N\) above \(B \subset G/B\), and let \(\mathcal{L}(N)\) denote the locally free \(O_{G/B}\)-module of its sections. We also denote by \(\mathcal{L}(N) \mid_{X_w}\) the restriction of \(\mathcal{L}(N)\) to \(X_w\).

Consider the adjoint action of \(B\) on the Lie algebra \(\mathfrak{u}\) of strictly upper triangular matrices. The \(B\)-stable (or “ad-nilpotent”) ideals of \(\mathfrak{u}\) are in bijection with root ideals via the map sending the root ideal \(\Psi\) to the \(B\)-submodule, call it \(\mathfrak{u}_\Psi\), of \(\mathfrak{u}\) with weights \(\{\epsilon_i - \epsilon_j \mid (i,j) \in \Psi\}\).

The character of a \(B\)-module \(N\) is \(\text{char}(N) = \sum_{\alpha \in \mathbb{Z}^\ell} \dim(N_\alpha)x^\alpha\), where \(N_\alpha = \{v \in N \mid \text{diag}(x_1,\ldots,x_\ell)v = x^\alpha v\}\) is the \(\alpha\)-weight space of \(N\) and \(x^\alpha := x_1^{\alpha_1} \cdots x_\ell^{\alpha_\ell}\). Let \(d\) be the \(\mathbb{Z}\)-linear operator on \(\mathbb{Z}[x_1^{\pm1},\ldots,x_\ell^{\pm1}]\) satisfying \(d(x^\alpha) = x^{-\alpha}\), so that \(\text{char}(N)^* = d(\text{char}(N))\); extend it to an operator on \(\mathbb{Z}[x_1^{\pm1},\ldots,x_\ell^{\pm1}]/[q]\) by \(d(\sum_{d \geq 0} f_d q^d) = \sum_{d \geq 0} d(f_d)q^d\).

For \(\gamma \in \mathbb{Z}^\ell\), let \(\mathbb{C}_\gamma\) denote the one-dimensional \(B\)-module of weight \(\gamma\).

We need the following result of Demazure [17, §5.5] (this assumes \(G\) is semisimple; see also [31, II.14.18 (a)] where reductive \(G\) are allowed).
Theorem 3.1. For any weight \( \gamma \in \mathbb{Z}^t \) and \( w \in S_t \),
\[
d \circ \pi_w \circ d(x^\gamma) = \sum_{i \geq 0} (-1)^i \text{char} \, H^i(X_w, \mathcal{L}(C_\gamma)).
\]

Nonsymmetric Catalan functions appear naturally as graded Euler characteristics, extending a description of the Catalan functions in [73, 15]:

**Theorem 3.2.** For any labeled root ideal \((\Psi, \gamma, w)\),
\[
H(\Psi; \gamma; w) = \text{poly} \circ d \left( \sum_{i,j \geq 0} (-1)^i q^j \text{char} \, H^i(X_w, \mathcal{L}(S^j u^*_\Psi \otimes C_\gamma^*)) \right),
\]
(3.1)

where \( S^j u^*_\Psi \) denotes the \( j \)-th symmetric power of the \( B \)-module \( u^*_\Psi \).

**Proof.** The series \( d \left( \prod_{(i,j) \in \Psi} (1 - qx_i/x_j)^{-1} x^\gamma \right) \) gives the character of \( \bigoplus_j S^j u^*_\Psi \otimes C_\gamma^* \) where \( q \) keeps track of the grading. Each homogeneous component \( S^j u^*_\Psi \otimes C_\gamma^* \) has a \( B \)-module filtration into one-dimensional weight spaces. Then by the additivity of the Euler characteristic and Theorem 3.1,
\[
\sum_{i,j \geq 0} (-1)^i q^j \text{char} \, H^i(X_w, \mathcal{L}(S^j u^*_\Psi \otimes C_\gamma^*)) = d \circ \pi_w \circ d \left( \prod_{(i,j) \in \Psi} (1 - qx_i/x_j)^{-1} x^\gamma \right).
\]

Applying \( \text{poly} \circ d \) to both sides, the right side becomes the nonsymmetric Catalan function \( H(\Psi; \gamma; w) \) from Definition 2.1 after using \( \text{poly} \circ \pi_w = \pi_w \circ \text{poly} \) (Proposition 5.5 (i)). \( \square \)

**Remark 3.3.** A version of (3.1) holds for any \( B \)-module \( N \), with the product over \( \Psi \) in the definition of \( H(\Psi; \gamma; w) \) replaced by a product over the multiset of weights of \( N \). However, restricting to the \( u^*_\Psi \) is natural from the geometric perspective of [73], e.g., for \( w = w_0 \) and \( \Psi = \Delta^+ \), \( H^i(G/B, \mathcal{L}(\bigoplus_j S^j u^*_\Psi \otimes C_\gamma^*)) \cong H^i(T^*(G/B), \theta^* \mathcal{L}(C_\gamma^*)) \), where \( T^*(G/B) \) is the cotangent bundle of the flag variety and \( \theta : T^*(G/B) \to G/B \) the projection.

For \( \nu = (\nu_1 \geq \cdots \geq \nu_t) \in \mathbb{Z}^t \), let \( V(\nu) \) be the irreducible \( G \)-module of highest weight \( \nu \). Let \( \alpha \in \mathbb{Z}^t \) and \( \alpha^+ \) be the weakly decreasing rearrangement of \( \alpha \). The Demazure module \( D(\alpha) \subset V(\alpha^+) \) is the \( B \)-module \( Bu_\alpha \), where \( u_\alpha \) is an element of the (one-dimensional) \( \alpha \)-weight space of \( V(\alpha^+) \). The Demazure atom module \( \hat{D}(\alpha) \) is the quotient of \( D(\alpha) \) by the sum of all Demazure modules properly contained in \( D(\alpha) \). The characters \( \kappa_\alpha(x) = \text{char}(D(\alpha)) \) and \( \hat{\kappa}_\alpha(x) = \text{char}(\hat{D}(\alpha)) \) are the key polynomial and Demazure atom, respectively which will be discussed further in §4.8 and §5.2.

As in [84, §2.3], say a \( B \)-module \( N \) has an excellent filtration (resp. relative Schubert filtration) if its dual \( N^* \) has a \( B \)-module filtration whose subsequents are isomorphic to Demazure modules (resp. Demazure atom modules).

**Conjecture 3.4.** Let \((\Psi, \mu, w)\) be a labeled root ideal with partition \( \mu \) and \( j \geq 0 \).

(i) The nonsymmetric Catalan function \( H(\Psi; \mu; w) \) is a positive sum of Demazure atoms, i.e., \( H(\Psi; \mu; w)(x; q) = \sum_\alpha K^{\Psi, w}_{\alpha, \mu}(q) \hat{\kappa}_\alpha(x) \) with \( K^{\Psi, w}_{\alpha, \mu}(q) \in \mathbb{Z}_{\geq 0}[q] \).

(ii) \( H^i(X_w, \mathcal{L}(S^j u^*_\Psi \otimes C_\mu^*)) = 0 \) for \( i > 0 \).

(iii) \( H^0(X_w, \mathcal{L}(S^j u^*_\Psi \otimes C_\mu^*)) \) has a relative Schubert filtration.

(iv) \( H^0(X_w, \mathcal{L}(S^j u^*_\Psi \otimes C_\mu^*)) \) has an excellent filtration when \((\Psi, \mu, w)\) is tame.
For tame \((\Psi, \mu, w)\), Corollary 2.9 implies (i), while conjectures (ii) and (iv) constitute a module-theoretic strengthening of this corollary. Similarly, (ii) and (iii) give a module-theoretic strengthening of (i).

In this paragraph we discuss the case of Conjecture 3.4. First note that the cohomology groups are \(G\)-modules, so (iii)–(iv) hold and (ii) implies (i). Conjecture (ii) was posed by Chen-Haiman [15, Conjecture 5.4.3]; this generalized a conjecture of Broer for parabolic \(\Psi\), which he settled in the dominant rectangle case [13, Theorem 2.2]. Hague [25, Theorems 4.15 and 4.23] extended this result to some other classes of weights (still parabolic \(\Psi\)). Panyushev proved that (ii) holds when the weight \(\mu - \rho + \sum_{(i,j) \in \Delta^+} \varepsilon_i - \varepsilon_j\) is weakly decreasing, where \(\rho = (\ell - 1, \ell - 2, \ldots, 0)\). Frobenius splitting methods [43] give another proof of a subcase of Broer’s result; this method has the advantage of applying to \(G\) over algebraically closed fields of prime characteristic.

When \(\Psi = \emptyset\), \(H^0(X_w, \mathcal{L}(\mathbb{C}_1)^*) = D(w\mu)\) (implying (iii)-(iv)) and the cohomology vanishing (ii) are results of Demazure [17, 18]; a gap in [17] is bypassed by another proof method of Andersen [3, §4.3]; see also II.14.18 (b) and II.14.15 (e) of [31].

4. BACKGROUND ON CRYSTALS

We begin by reviewing crystals for any symmetrizable Kac-Moody Lie algebra \(\mathfrak{g}\) and prove that restrictions of Demazure crystals are disjoint unions of Demazure crystals. We then fix notation and conventions for \(\mathfrak{g} = \widehat{\mathfrak{sl}}_k\) following Naoi [70] and Kac [33]; note that the notation \(I, P, P^+, \alpha_i, \alpha_i^\vee\) is for general \(\mathfrak{g}\) in §4.1–4.2 and for \(\mathfrak{sl}_k\) from §4.3 through the remainder of the paper.

4.1. \(U_q(\mathfrak{g})\)-(seminormal) crystals. The quantized enveloping algebra \(U_q(\mathfrak{g})\) is specified by a Dynkin node set \(I\), coweight lattice \(P^*\), weight lattice \(P = \text{Hom}_\mathbb{Z}(P^*, \mathbb{Z})\), coroots \(\{\alpha_i^\vee\}_{i \in I} \subset P^*\), roots \(\{\alpha_i\}_{i \in I} \subset P\), and a symmetric bilinear form \((\cdot, \cdot)\): \(P \times P \to \mathbb{Q}\) subject to several conditions (see [37, §2.1]). This data given, a \(U_q(\mathfrak{g})\)-seminormal crystal is a set \(B\) equipped with a weight function \(\text{wt}: B \to P\) and crystal operators \(\tilde{e}_i, \tilde{f}_i: B \sqcup \{0\} \to B \sqcup \{0\}\) \((i \in I)\) such that for all \(i \in I\) and \(b \in B\), there holds \(\tilde{e}_i(0) = \tilde{f}_i(0) = 0\) and

\[
\begin{align*}
\text{wt}(\tilde{e}_i b) &= \text{wt}(b) + \alpha_i \text{ whenever } \tilde{e}_i b \neq 0, \text{ and } \text{wt}(\tilde{f}_i b) = \text{wt}(b) - \alpha_i \text{ whenever } \tilde{f}_i b \neq 0; \\
\varepsilon_i(b) &= \max\{k \geq 0 \mid \tilde{e}_i^k b \neq 0\} < \infty, \quad \phi_i(b) := \max\{k \geq 0 \mid \tilde{f}_i^k b \neq 0\} < \infty; \\
(\alpha_i^\vee, \text{wt}(b)) &= \phi_i(b) - \varepsilon_i(b); \\
\tilde{f}_i(\tilde{e}_i b) &= b \text{ whenever } \tilde{e}_i b \neq 0, \text{ and } \tilde{e}_i(\tilde{f}_i b) = b \text{ whenever } \tilde{f}_i b \neq 0.
\end{align*}
\]

This agrees with the notion of a seminormal crystal in [37, §7], the notion of a crystal in [70], and the notion of a \(P\)-weighted \(I\)-crystal in [79].

A strict embedding of \(U_q(\mathfrak{g})\)-seminormal crystals \(B, B'\) is an injective map \(\Psi: B \sqcup \{0\} \to B' \sqcup \{0\}\) such that \(\Psi(0) = 0\) and \(\Psi\) commutes with \(\text{wt}, \varepsilon_i, \phi_i, \tilde{e}_i, \text{ and } \tilde{f}_i\) for all \(i \in I\). It is necessarily an isomorphism from \(B\) onto a disjoint union of connected components of \(B'\).

For \(U_q(\mathfrak{g})\)-seminormal crystals \(B_1\) and \(B_2\), their tensor product \(B_1 \otimes B_2 = \{b_1 \otimes b_2 \mid b_1 \in B_1, b_2 \in B_2\}\) is the \(U_q(\mathfrak{g})\)-seminormal crystal with weight function \(\text{wt}(b_1 \otimes b_2) = \text{wt}(b_1) \otimes \text{wt}(b_2)\).
Let \( J \subset I \) and \( \hat{P}^* \subset P^* \) be such that \( \{ \alpha^\vee_i \}_{i \in I} \subset \hat{P}^* \). As \( P = \text{Hom}_{\mathbb{Z}}(P^*, \mathbb{Z}) \), restricting maps from \( P^* \) to \( \hat{P}^* \) yields a projection \( z: P \to \hat{P} := \text{Hom}_{\mathbb{Z}}(\hat{P}^*, \mathbb{Z}) \). Assume that the sets \( \{ \alpha^\vee_i \}_{i \in I}, \{ \alpha_i \}_{i \in I}, \{ \alpha^\vee_i \}_{i \in J}, \{ z(\alpha_i) \}_{i \in I} \) are linearly independent. The algebra \( U_q(\mathfrak{g}) \) has generators \( e_i, f_i, i \in I \), and \( q^h, h \in P^* \). Let \( U_q(\mathfrak{g}, J) \subset U_q(\mathfrak{g}) \) be the subalgebra generated by \( e_i, f_i, i \in J \), and \( q^h, h \in P^* \); it is a quantized enveloping algebra and its defining data includes \( J, \{ \alpha^\vee_i \}_{i \in J} \subset \hat{P}^*, \{ z(\alpha_i) \}_{i \in I} \subset \hat{P} \).

It is straightforward to verify that for any \( M \) in \( \mathcal{O}_{\text{int}}(\mathfrak{g}) \), the local crystal basis of the \( U_q(\mathfrak{g}) \)-restriction of \( M \) is also a local crystal basis of the \( U_q(\mathfrak{g}, J) \)-restriction of \( M \) and so is isomorphic to the direct sum of local crystal bases of highest weight \( U_q(\mathfrak{g}, J) \)-modules by [34] (see [37, §4.6] for a similar result). Moreover, the associated \( U_q(\mathfrak{g}) \)-crystal \( B \) of \( (\mathcal{L}, \mathcal{B}) \) and \( U_q(\mathfrak{g}, J) \)-crystal \( \hat{B} \) of \( \text{Res}_{U_q(\mathfrak{g}, J)}(\mathcal{L}, \mathcal{B}) \) are related as follows: \( \hat{B} \) is obtained from \( B \) by replacing its weight function with \( z \circ wt: B \to \hat{P} \) and taking only the crystal operators \( \tilde{e}_i, \tilde{f}_i \) for \( i \in J \). We say \( \hat{B} \) is the \( U_q(\mathfrak{g}, J) \)-restriction of \( B \) and denote it \( \text{Res}_{J}B \) or similar—see §4.4.

The following crystal restriction theorem will be important for obtaining key positivity results. Its proof was communicated to us by Peter Littelmann, and we are also grateful to Wilberd van der Kallen who pointed us to his module-theoretic version [84, Theorem 6.3.1]. A more general module-theoretic version was recently given in [6, Appendix A].

**Theorem 4.1.** Let \( U_q(\mathfrak{g}, J) \subset U_q(\mathfrak{g}) \) be as above. For any \( U_q(\mathfrak{g}) \)-Dumazure crystal \( S \), \( \text{Res}_{J}S \) is isomorphic to a disjoint union of \( U_q(\mathfrak{g}, J) \)-Dumazure crystals.

Here, \( S = \mathcal{F}_{i_1} \cdots \mathcal{F}_{i_k} \{ u_{\Lambda} \} \subset B(\Lambda) \) for some highest weight \( U_q(\mathfrak{g}) \)-crystal \( B(\Lambda) \) (as in Definition 2.4) and \( \text{Res}_{J}S \) denotes the set \( S \) regarded as a subset of \( \text{Res}_{J}B(\Lambda) \), which is isomorphic to a disjoint union of highest weight \( U_q(\mathfrak{g}, J) \)-crystals by the discussion above.

**Proof.** As \( \{ \alpha^\vee_i \}_{i \in I} \) is linearly independent, we can choose \( \{ \Lambda_j \}_{j \in I} \subset P \) such that \( \langle \alpha^\vee_i, \Lambda_j \rangle = m \delta_{ij} \) for \( i, j \in I \) and \( m \in \mathbb{Z}_{\geq 1} \). Set \( \mathcal{J} = I \setminus J \) and \( \rho_{J} = \sum_{i \in J} \Lambda_i \). Put \( c = 1 + \max \{ \varepsilon_i(b) \mid \).

\[ \begin{align*}
\tilde{e}_i(b_1 \otimes b_2) &= \begin{cases} 
\tilde{e}_i b_1 \otimes b_2 & \text{if } \varepsilon_i(b_1) > \phi_i(b_2), \\
b_1 \otimes \tilde{e}_i b_2 & \text{if } \varepsilon_i(b_1) \leq \phi_i(b_2).
\end{cases} \\
\tilde{f}_i(b_1 \otimes b_2) &= \begin{cases} 
\tilde{f}_i b_1 \otimes b_2 & \text{if } \varepsilon_i(b_1) \geq \phi_i(b_2), \\
b_1 \otimes \tilde{f}_i b_2 & \text{if } \varepsilon_i(b_1) < \phi_i(b_2).
\end{cases}
\end{align*} \quad (4.1, 4.2) \]
b \in S}. Consider the $U_q(\mathfrak{g})$-crystal $B(c p_J)$ with highest weight element $u_{c p_J}$. Since $\phi_i(u_{c p_J}) = \langle \alpha_i^\vee, c p_J \rangle = c m$ for $i \in J$, the tensor product rule (4.2) implies
\[ \tilde{f}_i(b \otimes u_{c p_J}) \notin S \otimes u_{c p_J} \quad \text{for all } i \in J \text{ and } b \in S. \] (4.3)

By [32, §2.11], $S \otimes u_{c p_J}$ is a disjoint union of $U_q(\mathfrak{g})$-Demazure crystals, each of the form $\mathcal{F}_{i_1} \cdots \mathcal{F}_{i_m} (b \otimes u_{c p_J})$ for some $b \in S$ and, by (4.3), we must have $i_j \in J$; moreover, $\mathcal{F}_{i_1} \cdots \mathcal{F}_{i_m} (b \otimes u_{c p_J}) = (\mathcal{F}_{i_1} \cdots \mathcal{F}_{i_m} (b)) \otimes u_{c p_J}$, which follows from (4.2) and $\phi_i(u_{c p_J}) = \langle \alpha_i^\vee, c p_J \rangle = 0$ for $i \in J$. Thus $S$ is a disjoint union of sets of the form $\mathcal{F}_{i_1} \cdots \mathcal{F}_{i_m} (b)$, and these are $U_q(\mathfrak{g})$-Demazure crystals as $\tilde{e}_i(b \otimes u_{c p_J}) = 0$ implies $\tilde{e}_i(b) = 0$ for $i \in J$. \hfill \Box

**Remark 4.2.** Let $U_q(\mathfrak{g})_J \subset U_q(\mathfrak{g})$ be as above and assume $J = I$. Then a subset $S$ of a $U_q(\mathfrak{g})$-crystal $B$ is isomorphic to a disjoint union of $U_q(\mathfrak{g})$-Demazure crystals if and only if $\text{Res}_J S$ is isomorphic to a disjoint union of $U_q(\mathfrak{g})_J$-Demazure crystals. This is immediate from the definitions since $B$ and $\text{Res}_J B$ have the same $\tilde{f}_i$-edges for all $i \in J = I$.

4.3. **The affine Lie algebra $\hat{\mathfrak{sl}}_\ell$.** Let $\hat{\mathfrak{sl}}_\ell$ be the complex affine Kac-Moody Lie algebra of type $A_{\ell-1}^{(1)}$, with associated Dynkin nodes $I = \mathbb{Z}/\ell\mathbb{Z} = \{0, 1, \ldots, \ell - 1\}$ and Cartan matrix $A = (a_{ij})_{i,j \in I}$. Let $\mathfrak{h} \subset \hat{\mathfrak{sl}}_\ell$ be the Cartan subalgebra, which has a basis consisting of the simple coroots $\{\alpha_i^\vee | i \in I\} \subset \mathfrak{h}$ together with the scaling element $d \in \mathfrak{h}$. We have the simple roots $\{\alpha_i | i \in I\} \subset \mathfrak{h}^*$, with pairings $\langle \alpha_i^\vee, \alpha_j \rangle = a_{ij}$ and $\langle d, \alpha_i \rangle = \delta_0(i, j \in I)$. The fundamental weights $\{\Lambda_i | i \in I\} \subset \mathfrak{h}^*$ are defined by $\langle \alpha_i^\vee, \Lambda_j \rangle = \delta_{ij}$ for $i,j \in I$, $\langle d, \Lambda_0 \rangle = 0$, and
\[ \langle d, \Lambda_i - \Lambda_{i-1} \rangle = \frac{2 i - 1 - \ell}{2 \ell} \quad \text{for } i \in [\ell]. \] (4.4)

The convention (4.4) is implicit in [70] and ensures the extended affine Weyl group acts nicely on $\alpha_i$ and $\Lambda_i$, which will be important in §4.6. The $\{\Lambda_i | i \in I\}$ together with the null root $\delta = \sum_{i \in I} \alpha_i$ form a basis for $\mathfrak{h}^*$; note that $\langle \alpha_i^\vee, \delta \rangle = 0$ for $i \in I$ and $\langle d, \delta \rangle = 1$.

Let $P = \bigoplus_{i \in I} \mathbb{Z} \Lambda_i$ be the weight lattice and $P^+ = \sum_{i \in I} \mathbb{Z}_{\geq 0} \Lambda_i + \mathbb{Z}_{\geq 0} \delta$ the dominant weights. Let $\text{cl} : \mathfrak{h}^* \to \mathfrak{h}^*/C \delta$ be the weight lattice and $P = \bigoplus_{i \in I} \mathbb{Z} \Lambda_i$. Let $\text{aff} : \mathfrak{h}^*/C \delta \to \mathfrak{h}^*$ be the section of cl satisfying $\langle d, \text{aff}(\lambda) \rangle = 0$ for all $\lambda \in \mathfrak{h}^*/C \delta$. Set $\varpi_i = \text{aff}(\text{cl}(\Lambda_i - \Lambda_0))$ for $i \in I$ (hence $\varpi_0 = 0$).

Let $\mathfrak{sl}_\ell \subset \hat{\mathfrak{sl}}_\ell$ be the simple Lie subalgebra with Dynkin nodes $I \setminus \{0\} = [\ell - 1]$, Cartan subalgebra $\mathfrak{h} = \bigoplus_{i \in [\ell - 1]} \mathbb{C} \alpha_i^\vee \subset \mathfrak{h}$, and fundamental weights $\{\varpi_i | i \in [\ell - 1]\} \subset (\mathfrak{h})^*$. The associated weight lattice $\hat{\mathfrak{h}} = \bigoplus_{i \in [\ell - 1]} \mathbb{Z} \alpha_i^\vee \subset \mathfrak{h}$ is naturally viewed as the image of $P$ under the projection $\mathfrak{h}^* \to \mathfrak{h}^*/(C \delta \oplus \mathbb{C} \Lambda_0) = (\mathfrak{h})^*$; moreover, $\varpi_i$ maps to $\alpha_i$ and $\bigoplus_{i \in [\ell - 1]} \mathbb{Z} \varpi_i \subset \mathfrak{h}^*$ maps isomorphically onto $\hat{\mathfrak{h}} \subset (\mathfrak{h})^*$.

4.4. **Type A crystals.** Let $U_q(\hat{\mathfrak{g}}_J)$ be the quantized enveloping algebra specified by the data $I, \rho^* = \text{Hom}_{\mathbb{Z}}(P, \mathbb{Z}), P = \{\alpha_i^\vee\} | i \in I, \{\alpha_i\} | i \in I \}$ above and the symmetric bilinear form $(\cdot, \cdot) : P \times P \to \mathbb{Q}$ defined by $(\alpha_i, \alpha_j) = a_{ij}$, $(\alpha_i, \Lambda_0) = \delta_{i0}, (\Lambda_0, \Lambda_0) = 0$. The subalgebra $U_q(\mathfrak{gl}_\ell) \subset U_q(\hat{\mathfrak{g}}_J)$ fits the form in §4.2, with Dynkin node subset $[\ell - 1] \subset I$, coweight lattice $\bigoplus_{i \in [\ell - 1]} \mathbb{Z} \alpha_i^\vee$, and weight lattice $\hat{\mathfrak{h}}$. Let $U_q(\mathfrak{g}_\ell)$ be as in [37, §5]; data includes Dynkin nodes $[\ell - 1]$, weight lattice $\mathbb{Z}^\ell$, and roots $\{\epsilon_i - \epsilon_{i+1}\}_{i \in [\ell - 1]}$. 

\
Let \( U'_q(\widehat{\mathfrak{sl}}_\ell) \subset U_q(\widehat{\mathfrak{sl}}_\ell) \) be the subalgebra generated by \( e_i, f_i, i \in I \), and \( q^h, h \in P^*_\text{cl} = \bigoplus_{\ell \in I} \mathbb{Z} \alpha_i^\vee \); it can be considered a quantized enveloping algebra with data \( I, \{\alpha_i^\vee\}_{i \in I} \subset P^*_\text{cl}, \{\text{cl}(\alpha_i)\}_{i \in I} \subset P_\text{cl} \) (it fits the form in [37, Definition 2.1]), but note that the roots are not linearly independent. For \( U'_q(\widehat{\mathfrak{sl}}_\ell) \), we work with \( U'_q(\widehat{\mathfrak{sl}}_\ell) \)-seminormal crystals so that we can work with both KR crystals and restrictions of \( U_q(\widehat{\mathfrak{sl}}_\ell) \)-crystals and treat them uniformly, while for \( g = \mathfrak{sl}_\ell, \mathfrak{gl}_\ell \), or \( \widehat{\mathfrak{sl}}_\ell \) we only need \( U_q(g) \)-crystals.

We fix some notation for restricting crystals and specify the projection \( z \) of weight lattices (as in (4.2)) for each case. For a \( U_q(\mathfrak{gl}_\ell) \)-crystal (resp. \( U_q(\widehat{\mathfrak{sl}}_\ell) \)-crystal) \( B \), its \( U_q(\mathfrak{sl}_\ell) \)-restriction \( \text{Res}_{\mathfrak{sl}_\ell} B \) has edges \( \bar{e}_i, \bar{f}_i, i \in [\ell - 1] \), and \( z \) is the canonical projection \( \mathbb{Z}^\ell \to \mathbb{Z}^\ell/\mathbb{Z}(1, \ldots, 1) \cong \hat{P}, \epsilon_i \mapsto \bar{\epsilon}_i - \bar{\epsilon}_{i-1} \) (resp. \( P \to \hat{P} \)). For a \( U'_q(\widehat{\mathfrak{sl}}_\ell) \)-seminormal crystal \( B \), its \( U_q(\mathfrak{sl}_\ell) \)-restriction \( \text{Res}_{\mathfrak{sl}_\ell} B \) has edges \( \bar{e}_i, \bar{f}_i, i \in [\ell - 1] \), and \( z \) is the canonical projection \( P_\text{cl} \to \hat{P} \) (this does not fit the form in §4.2 and it need not yield a \( U_q(\mathfrak{sl}_\ell) \)-crystal, but it does so for all \( U'_q(\widehat{\mathfrak{sl}}_\ell) \)-seminormal crystals considered in this paper). For a \( U_q(\mathfrak{sl}_\ell) \)-crystal \( B \), its \( U'_q(\widehat{\mathfrak{sl}}_\ell) \)-restriction has the same edges as \( B \) and \( z \) is \( \text{cl} \colon P \to P_\text{cl} \) (it is easily verified that this always yields a \( U'_q(\widehat{\mathfrak{sl}}_\ell) \)-seminormal crystal).

4.5. The affine symmetric group and 0-Hecke monoid. The extended affine symmetric group \( \widehat{S}_\ell \) is the group generated by \( \tau \) and \( s_i \ (i \in I) \) with relations

\[
\begin{align*}
    s_i^2 &= \text{id} \\
    s_is_j &= s_js_i \quad \text{if} \ a_{ij} = 0 \quad \text{(equivalently,} \ i \notin \{j-1,j+1\}\text{)} \\
    s_is_{i+1}s_i &= s_{i+1}s_is_{i+1} \\
    \tau s_i &= s_{i+1}\tau \\
    \tau^\ell &= \text{id}
\end{align*}
\]

Here, \( i, j \) denote arbitrary elements of \( I = \mathbb{Z}/\ell\mathbb{Z} \). The affine symmetric group \( \widehat{S}_\ell \) is the subgroup of \( \widehat{S}_\ell \) generated by the \( s_i \) for \( i \in I \), and the symmetric group \( S_\ell \) is the subgroup generated by \( s_i \) for \( i \in [\ell - 1] \). We have \( \widehat{S}_\ell = \Sigma \rtimes \widehat{S}_\ell \), where \( \Sigma = \{\tau^i \mid i \in [\ell]\} \cong \mathbb{Z}/\ell\mathbb{Z} \); as in §2.2, we also denote by \( \tau \) the Dynkin diagram automorphism \( I \to I, i \mapsto i + 1 \), so that \( \tau s_i \tau^{-1} = s_{\tau(i)} \).

Following the conventions of [70], \( \widehat{S}_\ell \) is also naturally realized as a subgroup of \( GL(\mathfrak{h}^*) \): for \( i \in I \), \( s_i \) acts by \( s_i(\lambda) = \lambda - \langle \alpha_i^\vee, \lambda \rangle \alpha_i \) for \( \lambda \in \mathfrak{h}^* \), and \( \tau \in GL(\mathfrak{h}^*) \) is determined by \( \tau(\Lambda_i) = \Lambda_{i+1} \) for \( i \in I \) and \( \tau(\delta) = \delta \). Another useful description of \( \Sigma \subset \widehat{S}_\ell \) is as the subgroup of \( \widehat{S}_\ell \subset GL(\mathfrak{h}^*) \) which takes the set \( \{\alpha_i \mid i \in I\} \) to itself; moreover, \( \sigma(\alpha_i) = \alpha_{\sigma(i)} \) for all \( \sigma \in \Sigma, i \in I \).

The 0-Hecke monoid \( \tilde{\mathcal{H}}_\ell \) of \( \widehat{S}_\ell \) is the monoid generated by \( \tau \) and \( s_i \ (i \in I) \) with relations (4.6)–(4.9) (with \( s_i \)’s in place of \( s_i \)’s) together with

\[
s_i^2 = s_i \quad \text{(4.10)}
\]

for \( i \in I \). The 0-Hecke monoid \( \mathcal{H}_\ell \) of \( S_\ell \) is the submonoid of \( \tilde{\mathcal{H}}_\ell \) generated by \( s_i \) for \( i \in [\ell - 1] \).
The length of \( w \in \tilde{S}_\ell \), denoted \( \text{length}(w) \), is the minimum \( m \) such that \( w = s_{i_1}s_{i_2} \cdots s_{i_m} \) for some \( i_j \in I \). For \( w \in \tilde{S}_\ell \), we can write \( w = \tau^iv, \, v \in \tilde{S}_\ell \); define \( \text{length}(w) = \text{length}(v) \).

An expression for \( w \in \tilde{S}_\ell \) as a product of \( \tau^i \)'s and \( s_i \)'s is reduced if it uses \( \text{length}(w) \) \( s_i \)'s. Length and reduced expressions for elements of \( \tilde{H}_\ell \) are defined similarly.

### 4.6. Dynkin diagram automorphisms and crystals

Any \( \sigma \in \Sigma \), viewed as an element of \( GL(h^*) \), satisfies \( \sigma(P) = P \) and since \( \sigma(\delta) = \delta \), it also yields an element of \( GL(h^*/\mathbb{C}\delta) \) which satisfies \( \sigma(P_{cl}) = P_{cl} \); hence \( \sigma \) yields automorphisms of \( P \) and \( P_{cl} \).

For \( \sigma \in \Sigma \) and \( U(\widehat{sl}_\ell) \)-crystals (resp. \( U'(\widehat{sl}_\ell) \)-seminormal crystals) \( B, B' \), a bijection of sets \( \theta: B \to B' \) is a \( \sigma \)-twist if

\[
\sigma(\text{wt}(b)) = \text{wt}(\theta(b)), \quad \text{and} \quad \theta(\tilde{e}_i b) = \tilde{e}_{\sigma(i)} \theta(b), \quad \theta(\tilde{f}_i b) = \tilde{f}_{\sigma(i)} \theta(b) \quad \text{for all } i \in I, \quad \text{where } \theta(0) = 0.
\]

For any \( \Lambda \in P^+ \), there is a unique \( \sigma \)-twist \( \mathcal{F}_\sigma^\Lambda: B(\Lambda) \to B(\sigma(\Lambda)) \), which follows from \( \sigma(\alpha_i) = \alpha_{\sigma(i)} \) and the uniqueness of local crystal bases of highest weight modules [34].

It is easily verified that if \( \theta_1: B_1 \to B'_1 \) and \( \theta_2: B_2 \to B'_2 \) are \( \sigma \)-twists, then so is \( \theta_1 \otimes \theta_2: B_1 \otimes B_2 \to B'_1 \otimes B'_2 \). Thus the tensor product of maps

\[
\mathcal{F}_\sigma^\Lambda \otimes \cdots \otimes \mathcal{F}_\sigma^{\Lambda_p}: B(\Lambda^1) \otimes \cdots \otimes B(\Lambda^p) \to B(\sigma(\Lambda^1)) \otimes \cdots \otimes B(\sigma(\Lambda^p))
\]

is the natural choice of \( \sigma \)-twist from any tensor product \( B(\Lambda^1) \otimes \cdots \otimes B(\Lambda^p) \) of highest weight \( U_q(\widehat{sl}_\ell) \)-crystals, \( \Lambda^1, \ldots, \Lambda^p \in P^+ \). We let \( \mathcal{F}_\tau \) denote the operator on \( \mathcal{D}(\widehat{sl}_\ell) \) (see Definition 2.5) which takes \( S \subset B(\Lambda^1) \otimes \cdots \otimes B(\Lambda^p) \) to \( \mathcal{F}_\tau^\Lambda \otimes \cdots \otimes \mathcal{F}_\tau^{\Lambda_p}(S) \). This agrees with and explains the definition of \( \mathcal{F}_\tau \) in §2.2. Similarly, there is a unique \( \tau \)-twist of \( U'(\widehat{sl}_\ell) \)-seminormal crystals \( \mathcal{F}_\tau: \mathcal{B}^\mu \to \mathcal{B}^\mu \), explained in §6.6.

### 4.7. \( U_q(\widehat{sl}_\ell) \)-Demazure crystals

Recall that for a subset \( S \) of a seminormal crystal \( B \) and \( i \in I \), \( \mathcal{F}_i S = \{ \tilde{f}^k_i b \mid b \in S, k \geq 0 \} \setminus \{ 0 \} \subset B \).

**Proposition 4.3.** The operators \( \mathcal{F}_i \) (\( i \in I \)) and \( \mathcal{F}_\tau \) take \( U_q(\widehat{sl}_\ell) \)-Demazure crystals to \( U_q(\widehat{sl}_\ell) \)-Demazure crystals. Hence they can be regarded as operators on \( \mathcal{D}(\widehat{sl}_\ell) \) and as such they satisfy the 0-Hecke relations (4.6)–(4.10) of \( \tilde{H}_\ell \).

**Proof.** This follows from [70, Lemma 4.3] and its proof (which is largely based on [35]). \( \square \)

Thus for any \( w \in \tilde{H}_\ell \), we can define \( \mathcal{F}_w: \mathcal{D}(\widehat{sl}_\ell) \to \mathcal{D}(\widehat{sl}_\ell) \) by

\[
\mathcal{F}_w = \mathcal{F}_{c_1} \mathcal{F}_{c_2} \cdots \mathcal{F}_{c_m},
\]

where \( w = c_1 \cdots c_m \) with each \( c_j \in \{ s_i \mid i \in I \} \sqcup \{ \tau \} \) and \( \mathcal{F}_{s_i} := \mathcal{F}_i \), and this is independent of the chosen expression for \( w \). Recall that for \( \Lambda \in P^+ \) and \( w \in \tilde{H}_\ell \), \( B_w(\Lambda) := \mathcal{F}_w \{ u_\Lambda \} \).

We thus have \( \mathcal{F}_w B_w(\Lambda) = \mathcal{F}_w \mathcal{F}_w \{ u_\Lambda \} = \mathcal{F}_{w'w} \{ u_\Lambda \} = B_{w'w}(\Lambda) \) for any \( \Lambda \in P^+ \) and \( w, w' \in \tilde{H}_\ell \).
4.8. \(U_q(\mathfrak{gl}_\ell)-\text{Demazure crystals and key polynomials.}\) The symmetric group \(S_\ell\) acts on \(\mathbb{Z}^\ell\) by permuting coordinates. It is also convenient to define an action of \(H_\ell\) on \(\mathbb{Z}^\ell\) by

\[
s_i \alpha = \begin{cases} 
  s_i \alpha & \text{if } \alpha_i \geq \alpha_{i+1}, \\
  \alpha & \text{if } \alpha_i \leq \alpha_{i+1}.
\end{cases}
\]  
(4.11)

Let \(B^{\mathfrak{gl}}(\nu)\) denote the highest weight \(U_q(\mathfrak{gl}_\ell)\)-crystal and \(u_\nu\) its highest weight element, parameterized by \(\nu \in \{\lambda \in \mathbb{Z}^\ell \mid \lambda_1 \geq \cdots \geq \lambda_\ell\}\), the dominant integral weights for \(U_q(\mathfrak{gl}_\ell)\). Definition 2.4 defines \(U_q(\mathfrak{gl}_\ell)\)-Demazure crystals but let us make this more explicit. They are indexed by elements of \(\mathbb{Z}^\ell\). Let \(\alpha \in \mathbb{Z}^\ell\). Denote by \(\alpha^+\) the weakly decreasing re-arrangement of \(\alpha\) and \(p(\alpha) \in H_\ell\) the shortest element such that \(p(\alpha)\alpha^+ = \alpha\). Define the \(U_q(\mathfrak{gl}_\ell)\)-Demazure crystal indexed by \(\alpha\) to be \(BD(\alpha) = F_{p(\alpha)}(u_{\alpha^+}) \subset B^{\mathfrak{gl}}(\alpha^+)\).

**Remark 4.4.** Analogous results to §4.7 hold for \(U_q(\mathfrak{gl}_\ell)\)-Demazure crystals. In particular, the \(\mathcal{F}_i\) \((i \in [\ell - 1])\) can be regarded as operators on the set of \(U_q(\mathfrak{gl}_\ell)\)-Demazure crystals and as such satisfy the 0-Hecke relations (4.6), (4.7), (4.10) of \(H_\ell\).

Consider the group ring of the \(\mathfrak{gl}_\ell\)-weight lattice \(\mathbb{Z}[\mathbb{Z}^\ell] = \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}]\). It has the monomial basis \(x^\alpha := x_1^{\alpha_1}x_2^{\alpha_2} \cdots x_\ell^{\alpha_\ell}\), as \(\alpha\) ranges over \(\mathbb{Z}^\ell\). Recall from (2.1) that the Demazure operators \(\pi_i\) are given by \(\pi_i = \frac{x_i - s_i + 1}{x_i - 1}\) for \(i \in [\ell - 1]\). They were defined as operators on \(\mathbb{Z}[q][x]\), but we will also regard them as operators on \((\mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}])[q]\) or \(\mathbb{A}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}]\) for a ground ring \(\mathbb{A}\), given by the same formula. They satisfy the 0-Hecke relations (4.6), (4.7), (4.10) of \(H_\ell\) (see e.g. [74]). Thus, just as we discussed for \(\mathcal{F}_w\) in §4.7, \(\pi_w\) makes sense for any \(w \in H_\ell\) and \(\pi_w \pi_w' = \pi_{ww'}\) for all \(w, w' \in H_\ell\).

**Definition 4.5.** For \(\alpha \in \mathbb{Z}^\ell\), define the key polynomial or Demazure character by

\[
\kappa_\alpha = \pi_{p(\alpha)}x^{\alpha^+}.
\]  
(4.12)

If \(\alpha \in \mathbb{Z}^\ell\) is weakly decreasing, then \(\kappa_\alpha\) is simply the monomial \(x^\alpha\), while if \(\alpha\) is weakly increasing, then \(\kappa_\alpha\) is the Schur function \(s_{\alpha^+}(x) = s_{\alpha^+}(x_1, x_2, \ldots, x_\ell)\).

We record several facts about key polynomials for later use. First, it follows from \(\pi_{s_i} \pi_{w'} = \pi_{s_iw'}\) for all \(w' \in H_\ell\), that

\[
\pi_i \kappa_\alpha = \kappa_{s_i \alpha},
\]  
(4.13)

where \(s_i \alpha\) is as in (4.11).

Next, note that for \(f \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}]\), \(s_i(f) = f\) if and only if \(\pi_i(f) = f\) if and only if \(f\) is symmetric in \(x_i, x_{i+1}\). Further, for \(f, g \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}]\) with \(s_i(f) = f\),

\[
\pi_i(fg) = f\pi_i(g).
\]  
(4.14)

It is immediate from Definition 4.5 and (4.14) that

\[
(x_1 \cdots x_\ell)^d \kappa_\alpha = \kappa_{\alpha+(d, \ldots, d)}\ 	ext{for all } d \in \mathbb{Z} \text{ and } \alpha \in \mathbb{Z}^\ell.
\]  
(4.15)

**Proposition 4.6.** The key polynomials \(\{\kappa_\alpha \mid \alpha \in \mathbb{Z}^\ell\}_{\geq 0}\) form a basis for \(\mathbb{Z}[x_1, \ldots, x_\ell]\) and \(\{\kappa_\alpha \mid \alpha \in \mathbb{Z}^\ell\}\) form a basis for \(\mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}]\).

**Proof.** The first holds by [74, Corollary 7], and the second then follows from (4.15). \(\square\)

**Remark 4.7.** We caution that though the key polynomials \(\kappa_\alpha, \alpha \in \mathbb{Z}^\ell_{\geq 0}\), have the \(\mathfrak{gl}_{\infty}\)-stability property \(\kappa_\alpha = \kappa_{\alpha, 0} = \kappa_{\alpha, 0, 0} = \cdots\), this is not so for the \(\kappa_\beta\) with \(\beta \in \mathbb{Z}^\ell \setminus \mathbb{Z}^\ell_{\geq 0}\).
The character of a subset $S$ of a $U_q(\mathfrak{gl}_\ell)$-crystal is $\text{char}_{\mathfrak{gl}}(S) = \sum_{b \in S} x^{\text{wt}(b)} \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}]$.

**Proposition 4.8.** The characters of $U_q(\mathfrak{gl}_\ell)$-Demazure crystals are key polynomials: for any $\alpha \in \mathbb{Z}_\ell$,

$$\text{char}_{\mathfrak{gl}}(BD(\alpha)) = \sum_{b \in BD(\alpha)} x^{\text{wt}(b)} = \kappa_{\alpha}(x_1, \ldots, x_\ell).$$

**Proof.** This is a consequence of [35]. Note that the setup of [35] encompasses the $\mathfrak{gl}_\ell$ case with weight lattice $\mathbb{Z}_\ell$ (see [37, §5]), and the Demazure operators defined therein match the $\pi_i$ in the definition of key polynomials. □

5. The rotation theorem for tame nonsymmetric Catalan functions

We give the proof of the rotation Theorem 2.3, which requires Demazure operator identities and an in-depth study of polynomial truncation. Interestingly, the expression it gives for tame nonsymmetric Catalan functions is automatically polynomially truncated, whereas we had to explicitly add the truncation in our definition of these functions.

**Definition 5.1.** The polynomial truncation operator, denoted $\text{poly}$, is the linear operator on $\mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}]$ determined by its action on the basis $\{\kappa_\alpha | \alpha \in \mathbb{Z}_\ell\}$:

$$\text{poly}(\kappa_\alpha) = \begin{cases} 
\kappa_\alpha & \text{if } \alpha \in \mathbb{Z}_\ell^{\geq 0}, \\
0 & \text{otherwise}.
\end{cases}$$

We extend this in the natural way to a linear operator on $\mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}][[q]]$ by $\text{poly}(\sum_{d \geq 0} f_d q^d) = \sum_{d \geq 0} \text{poly}(f_d) q^d$ for any $f_d \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}]$.

5.1. Root expansion. A straightforward yet surprisingly powerful recursion played an important role for the Catalan functions in [11]. This is easily generalized to the nonsymmetric setting. For a root ideal $\Psi$, we say $\alpha \in \Psi$ is a removable root of $\Psi$ if $\Psi \setminus \alpha$ is a root ideal. For $\alpha = (i, j) \in \Delta_\ell^+$, write $\varepsilon_\alpha = \varepsilon_i - \varepsilon_j \in \mathbb{Z}_\ell$.

**Proposition 5.2.** Let $(\Psi, \gamma, w)$ be a labeled root ideal. For any removable root $\alpha$ of $\Psi$,

$$H(\Psi; \gamma; w) = H(\Psi \setminus \alpha; \gamma; w) + q H(\Psi; \gamma + \varepsilon_\alpha; w).$$

**Proof.** Apply the linear operator $\pi_w \circ \text{poly}$ to the following identity of series:

$$\prod_{(i,j) \in \Psi} (1 - qx_i/x_j)^{-1} x^\gamma = (1 - qx_\alpha)^{-1} \prod_{(i,j) \in \Psi \setminus \alpha} (1 - qx_i/x_j)^{-1} x^\gamma$$

$$= (1 + qx_\alpha (1 - qx_\alpha)^{-1}) \prod_{(i,j) \in \Psi \setminus \alpha} (1 - qx_i/x_j)^{-1} x^\gamma$$

$$= \prod_{(i,j) \in \Psi \setminus \alpha} (1 - qx_i/x_j)^{-1} x^\gamma + q \prod_{(i,j) \in \Psi} (1 - qx_i/x_j)^{-1} x^{\gamma + \varepsilon_\alpha}. \quad \square$$
5.2. Polynomial truncation. Polynomial truncation is better understood using the following symmetric bilinear form which comes from Macdonald theory and was given a self-contained treatment by Fu and Lascoux [21]. For \( f, g \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}] \), define

\[
(f, g) = \text{CT} \left( f(x_1, \ldots, x_\ell)g(x_\ell^{-1}, \ldots, x_1^{-1}) \prod_{(i,j) \in \Delta^\ell} (1 - x_i/x_j) \right),
\]

where \( \text{CT} \) denotes taking the constant term.

For \( \alpha \in \mathbb{Z}^\ell \), define the Demazure atom by \( \hat{\alpha} = \hat{\pi}(\alpha)x^\alpha \). Here, \( \hat{\pi}_i := \pi_i - 1 \) and \( \hat{\pi}_w := \hat{\pi}_i \cdots \hat{\pi}_m \), where \( w = s_i \cdots s_m \) is a reduced expression; this is well defined since the \( \hat{\pi}_i \) satisfy the braid relations.

**Theorem 5.3** ([21, Theorem 15]). The key polynomials and Demazure atoms are dual bases with respect to \( \langle \cdot, \cdot \rangle \): for \( \alpha, \beta \in \mathbb{Z}^\ell \), \( (\hat{\alpha}, \hat{\beta}) = \delta_{\alpha, \beta} \), where \( \delta \) is the Kronecker delta and \( w_0 \) is the longest permutation in \( S_\ell \).

**Proof.** The statement in [21, Theorem 15] is for \( \alpha, \beta \in \mathbb{Z}^\ell_{\geq 0} \), and this yields the statement for \( \alpha, \beta \in \mathbb{Z}^\ell \) too since it implies that for \( d \) sufficiently large, \( (\hat{\alpha}, \hat{\beta}) = \delta_{\alpha, \beta} \).

Hence, letting \( c_{\alpha, \beta} \in \mathbb{Z}_{\geq 0} \) denote the atom to monomial expansion coefficients, i.e., \( \hat{\alpha} = \sum_{\beta \in \mathbb{Z}^\ell} c_{\alpha, \beta} x^\beta \), the coefficient of \( \alpha \) in the key expansion of any \( f \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}] \) is given by

\[
\text{CT} \left( \prod_{(i,j) \in \Delta^+} (1 - x_i/x_j) \hat{\kappa}_{\alpha\beta}(x_\ell^{-1}, \ldots, x_1^{-1}) \right) = \sum_{\beta \in \mathbb{Z}^\ell} c_{\alpha, \beta} \text{CT} \left( \prod_{(i,j) \in \Delta^+} (1 - x_i/x_j)x^{-\text{rev}(\beta)} \right)
\]

\[
= \sum_{\beta \in \mathbb{Z}^\ell} c_{\alpha, \beta} \left( \text{coefficient of } x^{\text{rev}(\beta)} \text{ in the monomial expansion of } f \prod_{(i,j) \in \Delta^+} (1 - x_i/x_j) \right),
\]

where \( \text{rev}(\beta) := (\beta_\ell, \ldots, \beta_1) \) denotes the reverse of any \( \beta = (\beta_1, \ldots, \beta_\ell) \in \mathbb{Z}^\ell \). We package this into the following corollary:

**Corollary 5.4.** For \( f \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}] \),

\[
f = \sum_{\alpha, \beta \in \mathbb{Z}^\ell} c_{\alpha, \beta} \left( \text{coefficient of } x^{\text{rev}(\beta)} \text{ in } f \prod_{(i,j) \in \Delta^+} (1 - x_i/x_j) \right) \hat{\kappa}_\alpha,
\]

\[
\text{poly}(f) = \sum_{\alpha, \beta \in \mathbb{Z}^\ell_{\geq 0}} c_{\alpha, \beta} \left( \text{coefficient of } x^{\text{rev}(\beta)} \text{ in } f \prod_{(i,j) \in \Delta^+} (1 - x_i/x_j) \right) \hat{\kappa}_\alpha.
\]

**Proposition 5.5.** Let \( \gamma \in \mathbb{Z}^\ell \) and \( w \in \mathcal{H}_\ell \) be arbitrary.

(i) For any \( f \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}][[q]] \), \( \text{poly}(\pi_i(f)) = \pi_i(\text{poly}(f)) \).

(ii) For any \( \alpha \in \mathbb{Z}^\ell_{\geq 0} \), \( \text{poly}(x^\alpha) = x^\alpha \).

(iii) If \( \sum_{a=k}^\ell \gamma_a < 0 \) for some \( k \in [\ell] \), then \( \text{poly}(x^\gamma) = 0 \).

(iv) If \( \sum_{a=k}^\ell \gamma_a < 0 \) for some \( k \in [\ell] \), then \( H(\Psi; \gamma; w) = 0 \) for any root ideal \( \Psi \subset \Delta^+_\ell \).

(v) If \( \gamma_{m+1} = \cdots = \gamma_\ell = 0 \), then \( H(\Psi; \gamma; w) = H(\Psi'; \gamma; w) \) for any \( \Psi, \Psi' \subset \Delta^+_m \) such that \( \Psi \cap \Delta^+_m = \Psi' \cap \Delta^+_m \).
Proof. Statement (i) is immediate from the definition of polynomial truncation and (4.13). Both \( \{x^\alpha \mid \alpha \in \mathbb{Z}^\ell_{\geq 0} \} \) and \( \{\kappa_\alpha \mid \alpha \in \mathbb{Z}^\ell_{\geq 0} \} \) are \( \mathbb{Z} \)-bases for \( \mathbb{Z}[x_1, \ldots, x_\ell] \) (Proposition 4.6). Since poly acts as the identity on the latter basis by definition, (ii) follows.

To prove (iii), by (5.3), it suffices to show that for any term \( cx^\gamma \) in the monomial expansion of \( x^\gamma \prod_{(i,j) \in \Delta^+} (1 - x_i/x_j) \), we have \( \zeta \notin \mathbb{Z}^\ell_{\geq 0} \). Indeed, for such a term we must have \( \sum_{a=k}^\ell \zeta_a \leq \sum_{a=k}^\ell \gamma_a < 0 \) as needed.

To prove (iv), recall \( H(\Psi; \gamma; w) = \pi_w(\text{poly}(x^\gamma \prod_{(i,j) \in \Psi} (1 + q x_i/x_j + q^2 (x_i/x_j)^2 + \cdots ))) \) from Definition 2.1. Any term \( cx^\gamma = \prod_{(i,j) \in \Psi} q^{d_{ij}} (x_i/x_j)^{d_{ij}} \) arising in the expansion of the product over \( \Psi \) satisfies \( \sum_{a=k}^\ell \zeta_a \leq 0 \), so \( \sum_{a=k}^\ell (\gamma + \zeta)_a < 0 \) and \( \pi_w(\text{poly}(c x^{\gamma+\zeta})) = 0 \) by (iii). Thus \( H(\Psi; \gamma; w) = 0 \). Statement (v) follows similarly from the observation that any term \( cx^\gamma = \prod_{(i,j) \in \Psi} q^{d_{ij}} (x_i/x_j)^{d_{ij}} \) with \( d_{ij} > 0 \) for some root \( (i, j) \) with \( j > m \), satisfies \( \sum_{a=k}^\ell (\gamma + \zeta)_a < 0 \). \( \square \)

Corollary 5.6. The nonsymmetric Catalan functions lie in \( (\mathbb{Z}[q])[x_1, \ldots, x_\ell] \) rather than the larger \( (\mathbb{Z}[x_1, \ldots, x_\ell])[\![q]\!] \), i.e., they are finite sums of key polynomials \( \kappa_\alpha, \alpha \in \mathbb{Z}^\ell_{\geq 0} \), with coefficients which are polynomials in \( q \) with integer coefficients.

Proof. Similar to the proof of (iv) above, one checks that in computing \( H(\Psi; \gamma; w) \), any term \( q^d x^\gamma = \prod_{(i,j) \in \Psi} q^{d_{ij}} (x_i/x_j)^{d_{ij}} \) with \( d > \ell |\gamma| \) satisfies \( \sum_{a=k}^\ell (\gamma + \zeta)_a < 0 \) for some \( k \in [\ell] \). \( \square \)

5.3. Identities for Demazure operators and polynomial truncation. Recall from (2.4) that \( \Phi \) is the operator on \( \mathbb{Z}[q][x] \) given by \( \Phi(f) = f(x_2, \ldots, x_\ell, q x_1) \); here we will regard it as an operator on \( \mathbb{Z}[q, q^{-1}][x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}] \).

Proposition 5.7. For any \( f \in \mathbb{Z}[q, q^{-1}][x_1^{\pm 1}, \ldots, x_\ell^{\pm 1}] \),

\[
\pi_{i+1} \Phi(f) = \Phi \pi_{i}(f) \quad \text{for } i = 1, \ldots, \ell - 2.
\]

Thus, recalling that \( \tau_1 \tau^{-1} = \sigma_{i+1} \), we have

\[
\pi_{\tau \tau^{-1}} \Phi(f) = \Phi \pi_{\tau}(f) \quad \text{for any } \tau \in \mathcal{H}_{\ell-1} \times \mathcal{H}_1 \subset \mathcal{H}_\ell.
\]

Proof. This is a direct computation from the definition of the Demazure operator \( \pi_i \):

\[
\Phi(\pi_i(f)) = \Phi \left( \frac{x_i f - x_{i+1} s_i(f)}{x_i - x_{i+1}} \right) = \frac{x_{i+1} \Phi(f) - x_{i+2} s_{i+1}(\Phi(f))}{x_{i+1} - x_{i+2}} = \pi_{i+1}(\Phi(f)). \quad \square
\]

Lemma 5.8. For any \( f \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_{\ell-1}^{\pm 1}] \) and \( a \geq 0 \), \( \text{poly}(x_1^a \Phi(f)) = x_1^a \Phi(\text{poly}(f)) \).

Proof. Since poly and \( \Phi \) are linear operators, it is enough to prove this for \( f \) ranging over the \( \mathbb{Z} \)-basis \( \{\kappa_\zeta \mid \zeta \in \mathbb{Z}^{\ell-1} \} \) of \( \mathbb{Z}[x_1^{\pm 1}, \ldots, x_{\ell-1}^{\pm 1}] \). In light of Remark 4.7, computing \( \text{poly}(\kappa_\zeta) \) is nontrivial as we have defined polynomial truncation with respect to the basis \( \{\kappa_\alpha \mid \alpha \in \mathbb{Z}^\ell \} \) of \( \mathbb{Z}[x_1^{\pm 1}, \ldots, x_{\ell-1}^{\pm 1}] \). However, we can use Demazure operators: write \( \kappa_\zeta = \pi_v x^\mu(0) \) with \( \mu = \zeta^+ \in \mathbb{Z}^{\ell-1} \) and \( v = p(\zeta) \in \mathcal{H}_{\ell-1} \) as in Definition 4.5 but for \( \ell - 1 \) in place of \( \ell \). Then

\[
x_1^a \Phi(\text{poly}(\pi_v x^\mu(0))) = \pi_{\tau \tau^{-1}} x_1^a \Phi(\text{poly}(x^\mu(0))) = \begin{cases} 
\pi_{\tau \tau^{-1}}(x^\mu(0)) & \text{if } \mu \in \mathbb{Z}^\ell_{\geq 0} \\
0 & \text{otherwise},
\end{cases}
\]
where the first equality is by Propositions 5.5 (i) and 5.7 and then (4.14); the second equality uses Proposition 5.5 (ii) for the top line and Proposition 5.5 (iii) for the bottom line (µ weakly decreasing implies µ<sub>ℓ-1</sub> < 0 if µ ∉ ℤ<sub>≥0</sub>\(^{-1}\)).

On the other hand, there holds

\[
poly(x_1^a \Phi(\pi, x^\mu)) = \pi_{\tau \tau v^{-1}} \mbox{poly}(x_1^a \Phi(x^\mu)) = \pi_{\tau \tau v^{-1}} \mbox{poly}(x_{(a, \mu)}) = \begin{cases} 
\pi_{\tau \tau v^{-1}} x_{(a, \mu)} & \text{if } \mu \in \mathbb{Z}_{≥0}^{\ell-1} \\
0 & \text{otherwise.}
\end{cases}
\]

The justification is just as in the previous paragraph (the last equality uses a ≥ 0). □

Lascoux [55, §4.1] gives a partial description of a Monk’s rule for key polynomials, i.e. \(x_i \kappa_\alpha\) expanded in key polynomials. The computations therein are similar to the next three lemmas, which we need for polynomial part computations. Recall that \(\hat{\pi}_i = \pi_i - 1\).

**Lemma 5.9.** For any \(f \in \mathbb{Z}[x_{\ell+1}^1, \ldots, x_{\ell}^1]\),

\[
\begin{align*}
&x_{i+1} \hat{\pi}_i(f) = \hat{\pi}_i(x_i f) & \text{for } i \in [\ell - 1], \\
x_i^{-1} \hat{\pi}_i(f) = \hat{\pi}_i(x_i^{-1} f) & \text{for } i \in [\ell - 1], \\
x_i^{-1} \pi_{i-1}(f) = \pi_{i-1}(x_i^{-1} f) + x_i^{-1} f & \text{for } 2 \leq i \leq \ell.
\end{align*}
\]

**Proof.** The identity (5.4) is proved by direct computation:

\[
\hat{\pi}_i(x_i f) = \frac{x_i(x_i f) - x_{i+1}s_i(x_i f)}{x_i - x_{i+1}} - \frac{(x_i - x_{i+1})x_i f}{x_i - x_{i+1}} = \frac{x_{i+1}x_i f - x_i^{-1}s_i(f)}{x_i - x_{i+1}} = x_{i+1} \hat{\pi}_i(f).
\]

Multiplying both sides by \(x_i^{-1} x_{i+1}^{-1}\) (which commutes with \(\pi_i\)) yields (5.5), and (5.6) is a rearrangement of (5.4). □

**Lemma 5.10.** Let \(f \in \mathbb{Z}[x_{\ell+1}^1, \ldots, x_{\ell}^1]\) such that \(s_i(f) = f\) for \(a < i < \ell - 1\). Then

\[
x_{\ell} \hat{\pi}_{\ell-1} \hat{\pi}_{\ell-2} \cdots \hat{\pi}_a(x_a f) = \hat{\pi}_{\ell-1} \hat{\pi}_{\ell-2} \cdots \hat{\pi}_a(x_a f) = \hat{\pi}_{\ell-1} \hat{\pi}_{\ell-2} \cdots \hat{\pi}_a(x_a f).
\]

**Proof.** Applying (5.4) repeatedly yields the first equality of (5.7). For the second equality, we use that \(\hat{\pi}_i(f) = 0\) for \(i > a\) and \(\hat{\pi}_i \hat{\pi}_j = \hat{\pi}_j \hat{\pi}_i\) for \(i > j + 1\), and compute as follows:

\[
\begin{align*}
\hat{\pi}_{\ell-1} \cdots \hat{\pi}_a(x_a f) &= \hat{\pi}_{\ell-1} \cdots \hat{\pi}_{a+1} \hat{\pi}_a(x_a f) - \hat{\pi}_{\ell-1} \cdots \hat{\pi}_{a+1} (x_a f) \\
&= \hat{\pi}_{\ell-1} \cdots \hat{\pi}_{a+1} \pi_{a+1} (x_a f) - \hat{\pi}_{\ell-1} \cdots \hat{\pi}_{a+2} \pi_{a+1} (x_a f) - \hat{\pi}_{\ell-1} \cdots \hat{\pi}_{a+2} \pi_a (x_a f) \\
&= \hat{\pi}_{\ell-1} \cdots \hat{\pi}_{a+2} \pi_{a+1} \pi_a (x_a f) = \cdots = \hat{\pi}_{\ell-1} \hat{\pi}_{\ell-2} \cdots \hat{\pi}_a (x_a f).
\end{align*}
\]

**Lemma 5.11.** For \(i \in [\ell]\) and \(\alpha \in \mathbb{Z}^\ell\), \(x_i^{-1} \kappa_\alpha \in \mathbb{Z}\{\kappa_\beta \mid \beta^+ = \alpha^+ - \epsilon_j \text{ for some } j \in [\ell]\}\).

**Proof.** Write \(\kappa_\alpha = \pi_v x^\mu\) with \(\mu = \alpha^+\) and \(v = p(\alpha)\) as in Definition 4.5. The proof is by induction on length(v). For the base case \(v = id\), let \(z\) be the index such that \(\mu_i = \mu_{i+1} = \cdots = \mu_z > \mu_{z+1}\) (interpret \(\mu_{\ell+1} = -\infty\) so that \(z = \ell\) if \(\mu_i = \cdots = \mu_\ell\)). Then \(x_i^{-1} x^\mu = \hat{\pi}_i \hat{\pi}_{i+1} \cdots \hat{\pi}_{z-1} x_i^{-1} x^\mu\), which belongs to \(\mathbb{Z}\{\kappa_\beta \mid \beta^+ = \mu - \epsilon_j\}\) by (4.13).

Now suppose \(v \neq id\). Choose a length additive factorization \(v = s_j u\). Using (5.5) and (5.6) we obtain

\[
x_i^{-1} \pi_v x^\mu = x_i^{-1} \pi_j \pi_u x^\mu = \begin{cases} 
\pi_j x_i^{-1} \pi_u x^\mu + x_i^{-1} \pi_u x^\mu & \text{if } j = i - 1, \\
\hat{\pi}_j x_i^{-1} \pi_u x^\mu & \text{if } j = i, \\
\pi_j x_i^{-1} \pi_u x^\mu & \text{otherwise.}
\end{cases}
\]
By the inductive hypothesis, $x_{i-1}^{-1}\pi_u x^u$, $x_{i-1}^{-1}\pi_u x^u$, and $x_{i+1}^{-1}\pi_u x^u$ belong to $\mathbb{Z}\{\kappa_\beta \mid \beta^+ = \mu - \epsilon_j \text{ for some } j \in [\ell]\}$. Hence the result follows from (4.13).

**Lemma 5.12.** For any $f \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_{\ell}^{\pm 1}]$, $x_{\ell} \text{ poly}(x_{\ell}^{-1}\hat{\pi}_{\ell-1}(f)) = \text{poly}(\hat{\pi}_{\ell-1}(f))$.

**Proof.** It is enough to prove this identity for $f$ ranging over a $\mathbb{Z}$-basis of $\mathbb{Z}[x_1^{\pm 1}, \ldots, x_{\ell}^{\pm 1}]$. We choose the basis $\{x^\gamma \mid \gamma \in \mathbb{Z}_{\ell}\}_{0} \cup \{\kappa_\alpha \mid \alpha \in \mathbb{Z}_{\ell} \setminus \mathbb{Z}_{\ell}\}$. First consider $f = x^\gamma$ with $\gamma \in \mathbb{Z}_{\ell}\}_{0}$; set $c = \gamma_{\ell-1}, d = \gamma_{\ell}$. Then

$$\hat{\pi}_{\ell-1}x^\gamma = \begin{cases} x_1^{\gamma_1} \cdots x_{\ell-2}^{\gamma_{\ell-2}}(x_{\ell-1}^{c-\ell+1} + x_{\ell-1}^{d}x_{\ell}^{d+2} + \cdots + x_{\ell}^{d}x_{\ell-1}^{c}) & \text{if } c > d, \\
0 & \text{if } c = d, \\
-x_1^{\gamma_1} \cdots x_{\ell-2}^{\gamma_{\ell-2}}(x_{\ell-1}^{d} + x_{\ell-1}^{c-1}x_{\ell}^{d-1} + \cdots + x_{\ell}^{d}x_{\ell-1}^{c+1}) & \text{if } c < d. \end{cases}$$

Since $x_{\ell}$ appears with a positive power in each summand, we have $x_{\ell} \text{ poly}(x_{\ell}^{-1}\hat{\pi}_{\ell-1}x^\gamma) = \hat{\pi}_{\ell-1}x^\gamma = \text{poly}(\hat{\pi}_{\ell-1}x^\gamma)$ by Proposition 5.5 (ii).

Now consider $\alpha \in \mathbb{Z}_{\ell} \setminus \mathbb{Z}_{\ell}\}_{0}$. Since $\hat{\pi}_{\ell-1}\kappa_\alpha$ is a sum of key polynomials indexed by rearrangements of $\alpha$ (by (4.13)), $\text{poly}(\hat{\pi}_{\ell-1}\kappa_\alpha) = 0$. By Lemma 5.11, $x_{\ell}^{-1}\hat{\pi}_{\ell-1}\kappa_\alpha$ lies in $\mathbb{Z}\{\kappa_\beta \mid \beta^+ = \alpha^+ - \epsilon_j \text{ for some } j \in [\ell]\}$, so $\text{poly}(x_{\ell}^{-1}\hat{\pi}_{\ell-1}\kappa_\alpha) = 0$ as well. \qed

Let $w_{i,j} \in \mathcal{H}_{\ell}$ be the longest element of the submonoid generated by $s_i, \ldots, s_{j-1}$, i.e., the element of $\mathcal{H}_{\ell}$ corresponding to the permutation which reverses the interval $[i, j]$; we will also use the shorthand $w_{a} := w_{\{a,\ell\}}$.

**Corollary 5.13.** For any $g \in \mathbb{Z}[x_1^{\pm 1}, \ldots, x_{\ell}^{\pm 1}]$ and $a \in [\ell - 1]$,

$$\text{poly}(\hat{\pi}_{\ell-2}\hat{\pi}_{\ell-3} \cdots \hat{\pi}_a (x_{a} g)) + x_{\ell} \text{ poly}(\pi_{w_{a}}(g)) = \text{poly}(\pi_{w_{a}}(x_{a} g)). \quad (5.8)$$

**Proof.** Rewriting the right side of (5.8) using $\pi_{w_{a}} = \hat{\pi}_{\ell-1} \cdots \hat{\pi}_a \pi_{w_{a+1}}$, we obtain the equivalent statement

$$x_{\ell} \text{ poly}(\pi_{w_{a}}(g)) = \text{poly}(\hat{\pi}_{\ell-1}\hat{\pi}_{\ell-2} \cdots \pi_a (x_{a} g)).$$

To prove this, we compute

$$x_{\ell} \text{ poly}(\pi_{w_{a}}(g)) = x_{\ell} \text{ poly}(x_{\ell}^{-1}x_{\ell-1}\hat{\pi}_{\ell-2} \cdots \pi_a (\pi_{w_{a+1}} g))$$

$$= x_{\ell} \text{ poly}(x_{\ell}^{-1}\hat{\pi}_{\ell-1}\hat{\pi}_{\ell-2} \cdots \pi_a (x_{a} \pi_{w_{a+1}} g)) \text{ by Lemma 5.10}$$

$$= \text{poly}(\hat{\pi}_{\ell-1}\hat{\pi}_{\ell-2} \cdots \pi_a (x_{a} \pi_{w_{a+1}} g)) \text{ by Lemma 5.12}$$

$$= \text{poly}(\hat{\pi}_{\ell-1}\hat{\pi}_{\ell-2} \cdots \pi_a \pi_{w_{a+1}} (x_{a} g)) \text{ by (4.14)}. \qed$$

**5.4. Proof of Theorem 2.3.** The next theorem shows how to express a tame nonsymmetric Catalan function $H(\Psi; \gamma; w_{a+1})$ in terms of a smaller one $H(R(\Psi); R(\gamma); w_a)$ by peeling off its first row, which we can then iterate to unravel it one row at a time and obtain the desired expression involving $\pi_i$’s and $\Phi$’s.

**Theorem 5.14.** Let $\gamma \in \mathbb{Z}_{\ell}$ and $\Psi$ be a root ideal of length $\ell$. Let $R(\gamma) = (\gamma_2, \ldots, \gamma_\ell, 0)$ and $R(\Psi) \subset \Delta_{\ell}^+$ be $R(\Psi) := \{(i-1, j-1) \mid (i,j) \in \Psi, i > 1\} \cup \{(i, \ell) \mid i \in [\ell - 1]\}$; this is the root ideal obtained from $\Psi$ by removing its first row, shifting what remains up 1 and left 1, and adding a full column of roots on the right. Set $a = n(\Psi)$. If $\gamma_1 \geq 0$, then

$$H(\Psi; \gamma; w_{a+1}) = x_{a+1}^{\gamma_1} \Phi(H(R(\Psi); R(\gamma); w_a)). \quad (5.9)$$
Remark 5.15. The last column of roots in $R(\Psi)$ is just a place holder to make the right side a length $\ell$ nonsymmetric Catalan function: since $R(\gamma)_\ell = 0$, by Proposition 5.5 (v), $H(R(\Psi); R(\gamma); w_\delta) = H(\Psi'; R(\gamma); w_\delta)$ for any $\Psi' \subset \Delta^+_\ell$ with $\Psi' \cap \Delta^+_{\ell-1} = R(\Psi) \cap \Delta^+_{\ell-1}$.

Example 5.16. Let us verify Theorem 5.14 for $\ell = 2$, $\gamma = (3, 2)$, $\Psi = \Delta^+$. Then $a = 1$, $w_{a+1} = id$, $w_\delta = s_1$, $R(\gamma) = (2, 0)$, $R(\Delta^+) = \Delta^+$. We compute both sides of (5.9):

$$H(\Delta^+; \gamma; w_{a+1}) = \text{poly}(x_1^3x_2^2(1 - qx_1/x_2)^{-1})$$

$$= \text{poly}(x_1^3x_2^2 + qx_1x_2 + q^2x_1^2 + q^3x_1x_2 + \cdots) = x_1^3x_2^2 + qx_1^2x_2 + q^2x_1^2.$$

$$x_1^\gamma\Phi(H(R(\Delta^+); R(\gamma); w_\delta)) = x_1^\gamma\Phi_{p_1}(x_1^2) = x_1^\gamma\Phi(x_1^2(1 - qx_1/x_2)^{-1}) = x_1^\gamma\Phi_{p_1}(x_1^2) = x_1^\gamma\Phi(x_1^2 + x_1x_2 + x_2^2) = x_1^3x_2^2 + qx_1^2x_2 + q^2x_1^2.$$ 

Example 5.17. Let $\ell = 3$, $\gamma = 211$, and $\Psi = \Delta^+$. Then $a = 1$ and Theorem 5.14 yields $H(\Delta^+; 211; s_2) = x_1^3\Phi(H(\Delta^+; 110; w_0)).$ This can be viewed (via Corollary 7.13) as the identity of characters corresponding to going from the fourth to fifth crystal in Figure 1.

Proof of Theorem 5.14. The proof is by induction on $\sum_{j=2}^\ell \sum_{i=j}^{\ell} \gamma_i$ and $|\Psi|$. The former quantity is not bounded below, so to make this induction valid we first handle the following “base case”: suppose $\sum_{i=j}^{\ell} \gamma_i < 0$ for some $2 \leq j \leq \ell$. Thus $\sum_{i=j}^{\ell} R(\gamma)_i < 0$, and so by Proposition 5.5 (iv), $H(\Psi; \gamma; w_{a+1}) = 0 = x_1^\gamma\Phi(H(R(\Psi); R(\gamma); w_\delta)).$

Next, the base case $|\Psi| = 0$ holds by Lemma 5.8 (it is here we need $\gamma_1 \geq 0$):

$$H(\varnothing; \gamma; id) = \text{poly}(x^\gamma) = \text{poly}(x_1^\gamma\Phi(x^R(\gamma))) = x_1^\gamma\Phi(\text{poly}(x^R(\gamma))) = x_1^\gamma\Phi(H(R(\varnothing); R(\gamma); id));$$

we have also used Remark 5.15 for the last equality.

We may assume from now on that $|\Psi| > 0$ and $\sum_{i=j}^{\ell} \gamma_i \geq 0$ for $j \geq 2$. If there is a removable root $\alpha$ of $\Psi$ not in the first row, then

$$H(\Psi; \gamma; w_{a+1}) = H(\Psi \setminus \alpha; \gamma; w_{a+1}) + qH(\Psi; \gamma + \varepsilon_\alpha; w_{a+1})$$

$$= x_1^\gamma\Phi(H(R(\Psi \setminus \alpha); R(\gamma); w_\delta)) + qx_1^{\gamma_1}\Phi(H(R(\Psi); R(\gamma + \varepsilon_\alpha); w_\delta))$$

$$= x_1^\gamma\Phi(H(R(\Psi); R(\gamma); w_\delta),$$

where the first and third equalities are by Proposition 5.2 and the second is by the inductive hypothesis.

Now we may assume $\Psi$ consists of a single nonempty row. Hence we can expand on the only removable root $(1, a + 1)$ (Proposition 5.2) to obtain the first equality below:

$$H(\Psi; \gamma; w_{a+1}) = H(\Psi \setminus (1, a + 1); \gamma; w_{a+1}) + qH(\Psi; \gamma + \varepsilon_1 - \varepsilon_{a+1}; w_{a+1})$$

$$= \pi_{\ell-1}\pi_{\ell-2} \cdots \pi_{a+1}H(\Psi \setminus (1, a + 1); \gamma; w_{a+2}) + qH(\Psi; \gamma + \varepsilon_1 - \varepsilon_{a+1}; w_{a+1})$$

$$= \pi_{\ell-1}\pi_{\ell-2} \cdots \pi_{a+1}\pi_1^\gamma\Phi(H(\varnothing; R(\gamma); w_{a+1})) + qx_1^{\gamma_1}\Phi(H(\varnothing; R(\gamma) - \varepsilon_1; w_\delta))$$

$$= \pi_{\ell-1}\pi_{\ell-2} \cdots \pi_{a+1}\pi_1^\gamma\Phi\pi_{\delta}\text{poly}(x^{R(\gamma)}) + qx_1^{\gamma_1+1}\Phi\pi_{\delta}\text{poly}(x^{R(\gamma)} - \varepsilon_1)$$

$$= x_1^\gamma\Phi(\pi_{\ell-2}\pi_{\ell-3} \cdots \pi_1\pi_{a+1}\pi_{\delta}\text{poly}(x^{R(\gamma)}) + qx_1^{\gamma_1+1}\Phi\pi_{\delta}\text{poly}(x^{R(\gamma)} - \varepsilon_1))$$

$$= x_1^\gamma\Phi\pi_{\delta}\text{poly}(x^{R(\gamma)})$$

$$= x_1^\gamma\Phi(H(R(\varnothing); R(\gamma); w_\delta)).$$
The second equality is by \(\pi_{w_{a,1}} = \pi_{\ell-1}\pi_{\ell-2} \cdots \pi_{a+1}\pi_{w_{a,2}}\) and Definition 2.1, the third is by the inductive hypothesis and Remark 5.15 (note that we have the first part of \(\gamma + \epsilon_1 - \epsilon_{a+1}\) is still \(\geq 0\), the fifth is by Proposition 5.7, (4.14), and \(\Phi(x_\ell) = qx_1\), and the sixth is by Corollary 5.13 with \(g = x^{R(\gamma)-\epsilon_0}\) and Proposition 5.5 (i).

**Proof of Theorem 2.3.** Our goal is to prove (2.5), reproduced here for convenience:

\[
H(\Psi; \gamma; w) = \pi_v x_1^{\gamma_1} \Phi_{\Pi_{\Psi_1}(n_1)} x_1^{\gamma_2} \Phi_{\Pi_{\Psi_2}(n_2)} x_1^{\gamma_3} \cdots \Phi_{\Pi_{\Psi_{n_{\ell-1}}}(n_{\ell-1})} x_1^{\gamma_\ell}.
\]

We proceed by induction on \(m\), the minimum index such that \(\gamma_m = \gamma_{m+1} = \cdots = \gamma_\ell = 0\) (set \(m = \ell + 1\) if \(\gamma_\ell \neq 0\)). The base case \(m = 1\), \(\gamma = 0\) holds since \(H(\Psi; \gamma; w) = 1\) by Proposition 5.5 (v). Now assume \(m > 1\). By the tameness assumption, \(w\) has a length additive factorization \(w = v w_{n_1 + 1}\). Thus Theorem 5.14 gives

\[
H(\Psi; \gamma; w) = \pi_v H(\Psi; \gamma; w_{n_1 + 1}) = \pi_v x_1^{\gamma_1} \Phi(H(R(\Psi); R(\gamma); w_{n_1})).
\]

Applying the inductive hypothesis to \(H(R(\Psi); R(\gamma); w_{n_1})\), we obtain

\[
\pi_v x_1^{\gamma_1} \Phi(H(R(\Psi); R(\gamma); w_{n_1})) = \pi_v x_1^{\gamma_1} \Phi(\Pi_{\Psi_1}(n_1)) x_1^{\gamma_2} \Phi_{\Pi_{\Psi_2}(n_2)} x_1^{\gamma_3} \cdots \Phi_{\Pi_{\Psi_{n_{\ell-1}}}(n_{\ell-1})} x_1^{\gamma_\ell} = \pi_v \pi_{\Psi_{w_{n_1+1}}} x_1^{\gamma_1} \Phi_{\Pi_{\Psi_1}(n_1)} x_1^{\gamma_2} \Phi_{\Pi_{\Psi_2}(n_2)} x_1^{\gamma_3} \cdots \Phi_{\Pi_{\Psi_{n_{\ell-1}}}(n_{\ell-1})} x_1^{\gamma_\ell},
\]

giving the desired (2.5); for the second equality, we have used the operator identity

\[
x_1^{\gamma_1} \Phi_{\Pi_{\Psi_1}(n_1)} = x_1^{\gamma_1} \Phi_{\Pi_{\Psi_{w_{n_1+1}}}} x_1^{\gamma_1} \Phi_{\Pi_{\Psi_1}(n_1)} = \pi_{\Psi_{w_{n_1+1}}} x_1^{\gamma_1} \Phi_{\Pi_{\Psi_1}(n_1)},
\]

where the last equality is by Proposition 5.7 and (4.14). \(\square\)

6. DARK CRYSTALS AND KATABOLISM

We show that for any DARK crystal \(B^{\mu;w}\), katabolism is exactly the condition on Tabloids\(_{\ell}(\mu)\) which detects membership in \(\text{inv}(B^{\mu;w})\). A connection between KR crystals and Catalan functions in the dominant rectangle case has been well established (see Remark 2.19). One of our key insights is that to go beyond this case, DARK crystals are needed rather than full tensor products of KR crystals.

6.1. **Single row Kirillov-Reshetikhin crystals.** We will only need an explicit description of the KR crystals \(B^{1,s}_{\ell}\) in type A. For any positive integer \(s\), the \(U'_q(\mathfrak{sl}_\ell)\)-seminormal crystal \(B^{1,s}\) consists of all weakly increasing words of length \(s\) in the alphabet \([\ell]\), with weight function \(w_t: B^{1,s} \rightarrow P_{\ell}\) given by

\[
\text{wt}(b) = cl(c_1(\Lambda_1 - \Lambda_0) + c_2(\Lambda_2 - \Lambda_1) + \cdots + c_\ell(\Lambda_0 - \Lambda_{\ell-1})), \quad \text{for } b = 1^{c_1} 2^{c_2} \cdots \ell^{c_\ell} \quad (6.1)
\]

(i.e., \(b\) is the weakly increasing word with content \((c_1, \ldots, c_\ell)\), and crystal operators defined as follows: for \(i \in [\ell - 1]\) and \(b \in B^{1,s}\), \(\tilde{e}_i(b)\) is obtained from \(b\) by changing its leftmost \(i + 1\) to an \(i\), and \(\tilde{f}_i(b)\) by changing its rightmost \(i\) to an \(i + 1\); if there are no \(i + 1\)’s, \(\tilde{e}_i(b) = 0\), and if there are no \(i\)’s, \(\tilde{f}_i(b) = 0\). The element \(\tilde{e}_0(b)\) is obtained from \(b\) by removing a letter 1 from the beginning and adding a letter \(\ell\) to the end, and \(\tilde{f}_0(b)\) is obtained by removing a letter \(\ell\) from the end and adding a letter 1 to the beginning; if there are no 1’s, \(\tilde{e}_0(b) = 0\), and if there are no \(\ell\)’s, \(\tilde{f}_0(b) = 0\). See Figure 3.

We also define \(B^{1,0} = \{b_0\}\) to be the trivial \(U'_q(\mathfrak{sl}_\ell)\)-seminormal crystal, i.e., \(\text{wt}(b_0) = 0\) and \(\tilde{e}_i(b_0) = \tilde{f}_i(b_0) = 0\) for all \(i \in I\), and view \(b_0\) as the empty word.
6.2. Products of KR crystals. We now describe in detail the crystals \( B^\mu \) which were briefly introduced in §2.3.

**Definition 6.1.** A *biword* is a pair of words \( b = \left( \begin{array}{cccc} v_1 & v_2 & \cdots & v_m \\ w_1 & w_2 & \cdots & w_m \end{array} \right) \) with \( v_i, w_i \in \mathbb{Z}_{\geq 1} \), such that for \( i < j \), \( v_i > v_j \) or \( v_i = v_j \) and \( w_i \leq w_j \). Define \( \text{top}(b) := v_1 \cdots v_m \), the top word of \( b \), and \( \text{bottom}(b) := w_1 \cdots w_m \), the bottom word of \( b \). The \( i \)-th block of \( b \), denoted \( b_i \), is the (contiguous) subword of \( w_1 \cdots w_m \) below the letters \( i \) in \( v_1 \cdots v_m \). Thus a pair of words \( b \) is a biword if and only if \( \text{top}(b) \) is weakly decreasing and its blocks are weakly increasing. The *content* of \( b \), denoted \( \text{content}(b) \), is the vector \((c_1, c_2, \ldots, c_\ell)\), where \( c_i \) is the number of occurrences of the letter \( i \) in \( \text{bottom}(b) \).

Recall that for a partition \( \mu = (\mu_1 \geq \cdots \geq \mu_p \geq 0) \), we let \( B^\mu = B^{1,\mu_p} \otimes \cdots \otimes B^{1,\mu_1} \), a \( U_q(\widehat{\mathfrak{g}l}_\ell) \)-seminormal crystal. We identify its elements with the biwords whose bottom word has letters in \([\ell]\) and whose top word is \( p^{\mu_p} \cdots 2^{\mu_2} 1^{\mu_1} \) (see Example 6.6); we use a biword \( b \) interchangeably with its bottom word when the crystal \( B^\mu \) it belongs to is clear.

**Remark 6.2.** We can also regard \( B^\mu \) as a \( U_q(\mathfrak{gl}_\ell) \)-crystal (temporarily denote it \( B^\mu_{\mathfrak{gl}} \)) with weight function \( B^\mu_{\mathfrak{gl}} \to \mathbb{Z}_\ell \), \( b \mapsto \text{content}(b) \) and the same edges as \( \text{Res}_{\mathfrak{sl}_\ell} B^\mu \) (the restriction from \( U_q(\widehat{\mathfrak{sl}_\ell}) \) to \( U_q(\mathfrak{sl}_\ell) \)); moreover, \( \text{Res}_{\mathfrak{sl}_\ell} B^\mu_{\mathfrak{gl}} = \text{Res}_{\mathfrak{sl}_\ell} B^\mu \) by (6.1). From now on we write \( B^\mu \) for both the \( U_q(\widehat{\mathfrak{sl}_\ell}) \)-semionormal and \( U_q(\mathfrak{gl}_\ell) \)-crystal, and will clarify when necessary.

The crystal operators \( \tilde{e}_i \) and \( \tilde{f}_i \) on \( B^\mu \) are determined by the above description of \( \tilde{e}_i \) and \( \tilde{f}_i \) on \( B^{1,s} \) and the tensor product rule (4.1)–(4.2). For \( i \in [\ell - 1] \), they have the following streamlined description. Let \( b \in B^\mu \). Place a left parenthesis “(” below each letter \( i + 1 \) in \( b \) and a right parenthesis “)” below each letter \( i \). Match parentheses in the usual way. The unmatched parentheses correspond to a subword consisting of \( i \)’s followed by \( i + 1 \)’s. Then \( \tilde{e}_i(b) \) is obtained from \( b \) by changing the leftmost unmatched \( i + 1 \) to an \( i \), and \( \tilde{f}_i(b) \) by changing the rightmost unmatched \( i \) to an \( i + 1 \); if there are no unmatched \( i + 1 \)’s, \( \tilde{e}_i(b) = 0 \), and if there are no unmatched \( i \)’s, \( \tilde{f}_i(b) = 0 \).

**Example 6.3.** We illustrate the parentheses matching rule for computing \( \tilde{e}_2 \) and \( \tilde{f}_2 \) of the element \( b \in B^{554} \) below, with the unmatched letters in bold.

\[
\begin{align*}
b &= 2234 \ 2233 \ 11122 \\
\tilde{e}_2(b) &= 2234 \ 2233 \ 11122 \\
\tilde{f}_2(b) &= 2234 \ 2333 \ 11122
\end{align*}
\]

6.3. RSK and crystals. We review the beautiful connection between \( U_q(\mathfrak{gl}_\ell) \)-crystals and classical tableau combinatorics, which may be attributed to Kashiwara-Nakashima [38], and Lascoux-Schützenberger [57] who anticipated much of the combinatorics before the development of crystals. Other good references include [80] and [28, Chapter 7].

The crystals \( B^\mu \) are compatible with the following variant of the Robinson-Schensted-Knuth correspondence described in [22, A.4.1, Proposition 2]. Let \( b \) be a biword. The *insertion tableau* \( P(b) \) of \( b \) is the ordinary insertion tableau of the word \( \text{bottom}(b) \). It can be obtained by applying the Schensted row insertion algorithm to the letters of \( \text{bottom}(b) \)
from left to right or by column inserting each letter from right to left. The \textit{recording tableau} \(Q(b)\) of \(b\) is obtained by column inserting the bottom word of \(b\) from right to left and recording each newly added box with the corresponding top letter. More precisely, \(Q(b)\) is the tableau with the same shape as \(P(b)\) such that the skew shape \(\text{shape}(P(b^b^{-1} \cdots b^1))/\text{shape}(P(b^1 \cdots b^1))\) is filled with \(i\)'s for all \(i\).

Recall from §2.4 that SSYT\(_\ell(\mu)\) denotes the subset of Tabloids\(_\ell(\mu)\) consisting of tabloids with partition shape whose columns strictly increase from top to bottom. (This is the set of semistandard Young tableaux of content \(\mu\) with at most \(\ell\) rows, but with the fine print that we regard them as having \(\ell\) rows some of which may be empty.)

**Theorem 6.4** (see [80, Theorem 3.6]). The decomposition of the \(U_q(\mathfrak{gl}_\ell)\)-crystal \(B^\mu\) into highest weight \(U_q(\mathfrak{gl}_\ell)\)-crystals is given by

\[
B^\mu = \bigsqcup_{U \in \text{SSYT}_\ell(\mu)} C_U, \quad \text{where } C_U := \{b \in B^\mu \mid Q(b) = U\} \cong B^{\ell}(\text{shape}(U)). \tag{6.2}
\]

Here, \(B^{\ell}(\nu)\) denotes the highest weight \(U_q(\mathfrak{gl}_\ell)\)-crystal of highest weight \(\nu\).

### 6.4. The \textit{inv} bijection and RSK.

A biword can be thought of as a sequence of biletters \((v_1') (v_2') \cdots (v_m')\) which is weakly decreasing for the order \((v') \geq (v')'\) if and only if \(v > v'\) or \((v = v')\text{ and } w \leq w'\). Then, for a biword \(b\), define \(\text{inv}(b)\) to be the result of exchanging the top and bottom words of \(b\) and then sorting biletters to be weakly decreasing.

It is natural to regard \(\text{inv}\) as an involution on the set of biwords. However, as discussed in Remark 6.7 below, we prefer to think of \(\text{inv}\) as a bijection between biwords and tabloids, which we can do since biwords and tabloids may be naturally identified by equating blocks with rows (see the right side of (6.3)). Since the contents of the top and bottom words are exchanged by \(\text{inv}\), it restricts to a bijection \(\text{inv}: B^\mu \leftrightarrow \text{Tabloids}_\ell(\mu)\), which takes content to shape (we gave a direct description of the map \(B^\mu \rightarrow \text{Tabloids}_\ell(\mu)\) in §2.3).

**Proposition 6.5** ([22, A.4.1, Symmetry Theorem B]). The insertion \((P)\) and recording \((Q)\) tableaux are exchanged by \(\text{inv}\). In particular, for a biword \(b \in B^\mu\), \(Q(b) = P(\text{inv}(b))\) and for a tabloid \(T \in \text{Tabloids}_\ell(\mu)\), \(P(T) = Q(\text{inv}(T))\).

**Example 6.6.** For the following biword \(b \in B^{554}\), we compute \(\text{inv}(b)\) and \(Q(b)\):

\[
b = \begin{pmatrix} 3333 & 2222 & 1111 & 1111 & 1111 \\ 2234 & 1333 & 44 & 111 & 1111 \\ 2222 & 1111 & 1111 & 1111 & 1111 \end{pmatrix} \overset{\text{inv}}{\longrightarrow} \begin{pmatrix} 44 & 3333 & 2222 & 1111 \\ 23 & 2223 & 1133 & 1112 \end{pmatrix} = T \tag{6.3}
\]
Definition 6.8. i.e., the last element in the list \( b, \tilde{e}_i(b), \tilde{e}_i^2(b), \ldots \) which is not 0. For example, in the crystal \( B_{432} \), \( \tilde{e}_1^{\text{max}}(121221222) = 1211221111 \). More generally, for \( w \in H_\ell \), let \( w = s_{i_1} \cdots s_{i_m} \) be any expression for \( w \) as a product of \( s_i \)'s; define \( \tilde{e}_w^{\text{max}} = \tilde{e}_{i_1}^{\text{max}} \cdots \tilde{e}_{i_m}^{\text{max}} \); by Proposition 6.11 (ii) below, this is independent of the chosen expression for \( w \).

Recall that \( T^i \) denotes the \( i \)-th row of a tabloid \( T \).

Definition 6.8 (Partial insertion). Given a tabloid \( T \), \( P_i(T) \) is the tabloid obtained from \( T \) by replacing rows \( i \) and \( i+1 \) of \( T \) by the tableau \( P(T^i+1T^i) \) (if \( P(T^{i+1}T^i) \) has only one row, then the \( i+1 \)-st row of \( P_i(T) \) is empty). More generally, for \( w = s_{i_1} \cdots s_{i_m} \in H_\ell \), define \( P_w = P_{i_1} \cdots P_{i_m} \); by Proposition 6.11 (iii) below, this is independent of the chosen expression for \( w \). For this reason, this is related to Definition 2.13, see Remark 6.16.

For example, \( P_2 \left( \begin{array}{cccc} 1 & 1 & 2 & 2 \\ 1 & 2 & 3 & 4 \\ 1 & 1 & 2 & 2 \\ 2 & 3 \\ 3 & 4 \\ 2 & 3 \\ 3 & 4 \end{array} \right) = \begin{array}{cccc} 1 & 1 & 2 & 2 \\ 1 & 1 & 2 & 2 \\ 1 & 1 & 2 & 2 \\ 2 & 3 \\ 3 & 4 \\ 2 & 3 \\ 3 & 4 \end{array} \).

The following commutative diagrams give a summary of §6.4–6.5 (the left holds by Proposition 6.9 and the right by Propositions 6.5, 6.9, and 6.11 (iv)).

\[
\begin{array}{ccc}
\mathcal{B}_\mu & \xleftarrow{\text{inv}} & \text{Tabloids}_\ell(\mu) \\
\tilde{e}_i^{\text{max}} & \xrightarrow{P_i} & 0^{\text{max}}_w \\
\mathcal{B}_\mu & \xleftarrow{\text{inv}} & \text{Tabloids}_\ell(\mu) \\
\end{array}
\]

\[
\begin{array}{ccc}
\mathcal{B}_\mu & \xleftarrow{\text{inv}} & \text{Tabloids}_\ell(\mu) \\
\tilde{e}_i^{\text{max}} & \xrightarrow{Q} & P = P_{\sigma_0} \\
\mathcal{B}_\mu & \xleftarrow{\text{inv}} & \text{Tabloids}_\ell(\mu) \\
\end{array}
\]

Proposition 6.9. For any biword \( b \in \mathcal{B}_\mu \) and \( i \in [\ell - 1] \), \( \tilde{e}_i^{\text{max}}(b) = \text{inv}(P_i(\text{inv}(b))) \).

Proof. Set \( T = \text{inv}(b) \). Recall from §6.2 that \( \tilde{e}_i^{\text{max}}(b) \) is obtained by viewing \( i + 1 \)'s and \( i \)'s as left and right parentheses and then changing all unmatched \( i + 1 \)'s to \( i \)'s. We claim that \( \text{inv}(P_i(\text{inv}(b))) \), computed using the row bumping algorithm, is obtained by the same rule except with the following greedy parentheses matching in place of the ordinary one:
read “)”s from right to left and match each with the rightmost unmatched “(”. To see this, first note that the letters in top(b) above the i’s (resp. i + 1’s) in bottom(b) are the values of $T^i$ (resp. $T^{i+1}$). The row bumping algorithm computes $P_i(T)$ by processing the letters of $T^i$ from left to right; each letter $x$ of $T^i$ bumps the smallest entry of $T^{i+1}$ greater than $x$ not already bumped (if it exists). Each bump corresponds to a greedy-matched pair in $b$ and the unmatched i + 1’s of $b$ correspond to the entries of $T^{i+1}$ not bumped, which are exactly the ones that move from $T^{i+1}$ to $(P_i(T))^i$ in computing $P_i(T)$.

It remains to show that, given a string $w_1 \cdots w_m$ in the letters “(” and “)”, the ordinary and greedy matching rules produce the same unmatched “)’s. We proceed by induction on $m$. Consider the subword $w_i \cdots w_m$ where $w_i$ is the rightmost matched “)”; it must look like $( \ldots ) ( \ldots$. Let $(w_i, w_j)$ (resp. $(w_i, w_{i+1})$) be the greedy (resp. ordinary) matched pair in this subword. Though these pairs typically differ, deleting the greedy-matched pair yields the same string as deleting the ordinary matched pair. Since the position of the “)” in both pairs is the same, the result follows by the inductive hypothesis. □

**Proposition 6.10.** Let $b \in B^\nu$ and set $T = \text{inv}(b) \in \text{Tabloids}_{\ell}(\mu)$. Then $b$ is a $U_q(\mathfrak{gl}_\ell)$-highest weight element if and only if any of the following equivalent conditions holds:

(a) $\tilde{e}_i(b) = 0$ for all $i \in [\ell - 1]$,
(b) $P_i(T) = T$ for all $i \in [\ell - 1]$,
(c) $T$ is a tableau, i.e., $T \in \text{SSYT}_{\ell}(\mu)$.

**Proof.** Condition (a) is the definition of $b$ being a $U_q(\mathfrak{gl}_\ell)$-highest weight element. The equivalence (a) $\iff$ (b) is by Proposition 6.9, and (b) $\iff$ (c) is clear from computing $P(T^{i+1}T^i)$ by column insertion. □

**Proposition 6.11.** Let $B^\nu(\nu) = (\nu_1 \geq \cdots \geq \nu_\ell)$, be a highest weight $U_q(\mathfrak{gl}_\ell)$-crystal and $u_\nu$ its highest weight element. Then

(i) $F_w\{u_\nu\} = B^\nu(\nu)$.
(ii) The operators $\tilde{e}_1^{\text{max}}, \cdots, \tilde{e}_{\ell-1}^{\text{max}}$ on $B^\nu(\nu)$ satisfy the 0-Hecke relations of $\mathcal{H}_\ell$ ((4.6), (4.7), and (4.10)).
(iii) The operators $P_1, \ldots, P_{\ell-1}$ on Tabloids$_{\ell}$ satisfy the 0-Hecke relations of $\mathcal{H}_\ell$.
(iv) $\tilde{e}_w^{\text{max}}(b) = u_\nu$ for any $b \in B^\nu(\nu)$ and $P_{w_0}(T) = P(T)$ for any $T \in \text{Tabloids}_{\ell}$.

**Proof.** Statement (i) is well known; it can be deduced, for instance, from Remark 4.4 using that $B^\nu(\nu)$ is finite. Statement (iii) holds by (ii) and Proposition 6.9. For (ii), the $\tilde{e}_i^{\text{max}}$ clearly satisfy the relations (4.10); we now verify that they satisfy the braid relations (4.7) and omit the similar argument for (4.6). Let $b \in B^\nu(\nu)$. Let $U_q(\mathfrak{gl}_3) \subset U_q(\mathfrak{gl}_\ell)$ be the subalgebra isomorphic to $U_q(\mathfrak{gl}_3)$ associated to Dynkin node subset $J = \{i, i + 1\} \subset [\ell - 1]$. The component $B'$ of $\text{Res}_J B^\nu(\nu)$ containing $b$ is isomorphic to a highest weight $U_q(\mathfrak{gl}_3)$-crystal (see §4.2); let $u \in B'$ be its highest weight element. By (i) and Remark 4.4, $B' = F_1^* F_2^* F_1^* \{u\} = F_2^* F_1^* F_2^* \{u\}$; hence $\tilde{e}_i^{\text{max}} \tilde{e}_{i+1}^{\text{max}} \tilde{e}_i^{\text{max}}(b) = u = \tilde{e}_{i+1}^{\text{max}} \tilde{e}_i^{\text{max}} \tilde{e}_{i+1}^{\text{max}}(b)$.

For (iv), $\tilde{e}_w^{\text{max}}(b) = u_\nu$ holds by (i). Next, let $U = P(T)$ and $C_T$ be the $U_q(\mathfrak{gl}_\ell)$-crystal component containing $\text{inv}(T)$. By Proposition 6.10, the set $\text{inv}(C_T) = \{S \in \text{Tabloids}_{\ell}(\mu) \mid P(S) = U\}$ has a unique element fixed by $P_i$ for all $i \in [\ell - 1]$. Both $U$ and $P_{w_0}(T)$ satisfy this property by Proposition 6.10 and (iii), hence $P(T) = P_{w_0}(T)$. □
6.6. The kat and kat’ operators and the automorphism $\tau$. Recall from §4.6 that for $\sigma \in \Sigma = \{\tau^j \mid j \in \ell\}$ and $U'_q(\mathfrak{sl}_\ell)$-seminal crystals $B, B'$, a $\sigma$-twist is a bijection $B \to B'$ taking $i$-edges to $\sigma(i)$-edges. For a word $w$, let $\text{sort}(w)$ denote its weakly increasing rearrangement. For $m \in \mathbb{Z}$, let $\text{mod}_m^\ell(m)$ be the unique $i \in \ell$ such that $i \equiv m \mod \ell$.

**Proposition 6.12** ([70, Proposition 5.5]). There is a unique $\sigma$-twist $F_{\sigma}: B^\mu \to B^\mu$ for any $\sigma \in \Sigma$. The $\tau^{-1}$-twist $F_{\tau^{-1}}$ has the following explicit description: first, for $v = v_1 \cdots v_s \in B^{1,s}$, $F_{\tau^{-1}}(v_1 \cdots v_s) = \text{sort}(\text{mod}_1^\ell(v_1 - 1) \cdots \text{mod}_1^\ell(v_s - 1))$. Then for a biword $b \in B^\mu$ with blocks $b^p, \ldots, b^1$, bottom($F_{\tau^{-1}}(b)$) = $F_{\tau^{-1}}(b^p) \cdots F_{\tau^{-1}}(b^1)$ and top($F_{\tau^{-1}}(b)$) = top$(b)$.

For example, with $\ell = 4$ and $b = \begin{pmatrix} 444 & 3333 & 22222 & 11111 \ 233 & 1124 & 12223 & 11111 \end{pmatrix} \in B^{543}$, $F_{\tau^{-1}}(b) = \begin{pmatrix} 333 & 2222 & 11111 \ 122 & 1344 & 11124 \end{pmatrix} \in B^{543}$.

Recall from Definition 2.15 that for $T \in \text{Tabloids}_\ell$, kat$(T)$ is defined as follows: remove all 1’s from $T$ and left justify rows, then shift rows up by one cycling the first row to the $\ell$-th row, and finally subtract 1 from all letters. The operators kat and kat’ are conjugate under inv:

**Proposition 6.13.** For any $T \in \text{Tabloids}_\ell$, $\text{inv(kat}(T)) = \text{kat’}(\text{inv}(T))$.

**Proof.** For $j > 1$, let $a_1 \cdots a_m$ be the row indices of the letters $j$ in $T$, in weakly increasing order, which is also the block $\text{inv}(T)^j$. Since kat rotates rows, these $j$’s (which become $j - 1$’s in kat$(T)$) appear in rows $\text{mod}^\ell_1(a_1 - 1) \cdots \text{mod}^\ell_1(a_m - 1)$ of kat$(T)$. Thus

$$(\text{inv(kat}(T)))^{j - 1} = \text{sort( mod}^\ell_1(a_1 - 1) \cdots \text{mod}^\ell_1(a_m - 1) = (\text{kat’}(\text{inv}(T)))^{j - 1},$$

where the second equality is by Proposition 6.12 ($j - 1$ appears on the right and not $j$ because of the final step in the computation of kat’). The result follows. \hfill \Box

6.7. Katabolism.

**Definition 6.14.** Let $w = (w_1, \ldots, w_p) \in (\mathcal{H}_\ell)^p$. We say $T \in \text{Tabloids}_\ell$ is $w$-katabolizable if all the 1’s of $P_{w_1}(T)$ lie in its first row and kat($P_{w_1}(T)$) is $(w_2, \ldots, w_p)$-katabolizable. For $w$ the empty sequence, the only $w$-katabolizable tabloid is the empty one.

The streamlined version of katabolism from Definition 2.15 agrees with this one in the setting of Theorem 2.18, as we now verify.

**Proposition 6.15.** Let $\mu \in \mathbb{Z}_{\geq 0}^p$ and $n = (n_1, \ldots, n_{p - 1}) \in [\ell]^{p - 1}$ satisfy $n_{i+1} \geq n_i - 1$ for all $i \in [p - 2]$. A tableau $U \in \text{SSYT}_\ell(\mu)$ is $n$-katabolizable in the sense of Definition 2.15 if and only if it is $(\text{id}, s(n_1), \ldots, s(n_{p-1}))$-katabolizable.

**Proof.** We first verify the following claim: for any tabloid $T$ such that its subtabloid $T^{[i,\ell-1]}$ is a tableau, $P_i \cdots P_{\ell-1}(T)$ can be obtained by column inserting $T^\ell$ into $T^{[i,\ell-1]}$, i.e., $P_i \cdots P_{\ell-1}(T) = P_{i,\ell}(T)$ in the notation of Definition 2.13. To ease notation, assume
\[ i = 1, \] as this easily implies the general case. We have \( P_{1, \ell}(T) = P(T) \), the unique tableau with reading word Knuth equivalent to that of \( T \). Then by Proposition 6.11 (iv), \( P_{1, \ell}(T) = P(T) = P_{w_0}(T) = P_1 \cdots P_{\ell-1} P_{w_{[1, \ell-1]}}(T) = P_1 \cdots P_{\ell-1}(T) \), where the last equality uses that \( T^{[\ell-1]} \) is a tableau.

Let us now see that the tabloids produced in computing the two versions of katabolism are the same: set \( \bar{U} = \text{kat}(U) \). Since \( \bar{U}^{[\ell-1]} \) is a tableau, \( P_{n_1} \cdots P_{\ell-1}(\bar{U}) = P_{n_1, \ell}(\bar{U}) \) by the claim. Since \( (P_{n_1, \ell}(\bar{U}))^{[n_1, \ell]} \) is a tableau, so is \( \bar{U}^{[n_1-1, \ell-1]} \), for \( \bar{U} := \text{kat}(P_{n_1, \ell}(\bar{U})) \). As \( n_2 \geq n_1 - 1 \), \( \bar{U}^{[n_2, \ell-1]} \) is also a tableau. Hence \( P_{n_2} \cdots P_{\ell-1}(\bar{U}) = P_{n_2, \ell}(\bar{U}) \) again by the claim, and so on. \( \qed \)

**Remark 6.16.** With the assumption of Proposition 6.15, \( P_{n, \ell}(T) = P_{s(n)\ell}(T) = P_{n, \ell}(T) \) at every step of the katabolism algorithm, so in this sense the partial insertion of Definition 6.8 generalizes that of Definition 2.13. We caution however, that without this assumption, only Definition 6.14 should be used and not Definition 2.15.

**Example 6.17.** The following tabloid from Figure 2 (§2.7) is \((id, s_2s_1, s_2s_1)\)-katabolizable:

\[
\begin{array}{c|c|c|c|c|c}
1 & 1 & 2 & \text{kat} & 7 & 2 \\
\hline
3 & P_2 & 1 & 2 & P_1 & 1 \\
\hline
1 & 3 & \text{kat} & 7 & 1 & \text{kat} \\
\hline
\end{array}
\]

**Example 6.18.** Let \( \ell = 7, \mu = 4333332 \), and \( \Psi \) be the root ideal in red; \( \Delta^+ \setminus \Psi \) is shown in blue. We have \( n(\Psi) = (2, 3, 3, 3, 3, 1) \). We can visualize \( s(\Psi) = (s(n(\Psi)_1), \ldots, s(n(\Psi)_{\ell-1})) \) partially overlaid on the root ideal, so that row \( i \) read right to left is \( s(\Psi)_i \).

The following computation shows the tableau \( U \) below to be \( n(\Psi) \)-katabolizable or equivalently \((id, s(\Psi))\)-katabolizable (see Proposition 6.15). So this gives one term \( q^{\text{charge}(U)} s_{\text{shape}(U)} = q^{14}s_{876} \) of the Schur expansion of \( H(\Psi; \mu; w_0) \) from Theorem 2.18.
In contrast, the tableau $U'$ below is not $n(\Psi)$-katabolizable since the katabolism algorithm produces a tabloid with a 1 outside its first row just after an application of $P_{n(\Psi),1,\ell}$.

\[
U' = \begin{array}{cccccccc}

\end{array} \not \xrightarrow{\text{katabolizable}}
\]

**Remark 6.19.** Let $\mu = (\mu_1 \geq \cdots \geq \mu_\ell \geq 0)$ and $w = (w_1, \ldots, w_\ell) = (w_1, s(\Psi)) \in (\mathcal{H}_{\ell})^p$ for a root ideal $\Psi \subset \Delta^+_{\ell}$ which is empty in rows $\geq r$. Then $T \in \text{Tabloids}_{\ell}(\mu)$ is $w$-katabolizable $\iff T$ is $(w_1, \ldots, w_r, id, \ldots, id)$-katabolizable $\iff$ for $i \in [r - 1]$, the tabloid $U_i$ has all its 1’s on the first row, and $U_r$ is the superstandard tableau of shape and content $(\mu_r, \ldots, \mu_\ell)$, where $U_i := P_{w_i} \circ \text{kat} \circ \cdots \circ \text{kat} \circ P_{w_{i+1}} \circ \text{kat} \circ P_{w_{i+1}}(T)$.

**Theorem 6.20.** For $\mu = (\mu_1 \geq \cdots \geq \mu_p \geq 0)$ and $w = (w_1, \ldots, w_p) \in (\mathcal{H}_{\ell})^p$, $\text{inv}$ gives a bijection

\[
\{ T \in \text{Tabloids}_{\ell}(\mu) \mid T \text{ is } w\text{-katabolizable} \} \xrightarrow{\text{inv}} \mathcal{B}^{\mu,w}_{\ell}
\]

which takes shape to content.

**Proof.** We must show that for any $T \in \text{Tabloids}_{\ell}(\mu)$, $T$ is $w$-katabolizable if and only if $\text{inv}(T) \in \mathcal{B}^{\mu,w}_{\ell}$. We prove this by induction on $p + \sum_i \text{length}(w_i)$. The base case $p = 1$, $w_1 = id$ is clear. Now suppose $w_1 \neq id$. We can write $\mathcal{B}^{\mu,w} = \mathcal{F}_{w_1}(\mathcal{B}^{id,w_2,\ldots,w_p})$ and then

\[
\text{inv}(T) \in \mathcal{B}^{\mu,w}_{\ell}
\]

$\iff \bar{e}_{w_1}^{\text{max}}(\text{inv}(T)) \in \mathcal{B}^{id,w_2,\ldots,w_p}$

$\iff \text{inv}(\bar{e}_{w_1}^{\text{max}}(\text{inv}(T))) = P_{w_1}(T)$ is $(id, w_2, \ldots, w_p)$-katabolizable

$\iff T$ is $(w_1, w_2, \ldots, w_p)$-katabolizable,

where the second equivalence uses Proposition 6.9 and the inductive hypothesis.

Next suppose $p > 1$ and $w_1 = id$. Note that $\mathcal{B}^{\mu,w}_{\ell} = (\mathcal{F}_{\tau} \mathcal{B}^{(\mu_2,\ldots,\mu_p);(w_2,\ldots,w_p)}) \otimes b_{\mu_1}$. Then $\text{inv}(T) \in \mathcal{B}^{\mu,w}_{\ell}$ if and only if (1) the rightmost block of $\text{inv}(T)$ is $b_{\mu_1} = 1^{\mu_1}$ and (2) $b' \in \mathcal{F}_{\tau} \mathcal{B}^{(\mu_2,\ldots,\mu_p);(w_2,\ldots,w_p)}$, where $b'$ is the biword obtained from $\text{inv}(T)$ by removing this block of 1’s and subtracting 1 from its top letters. By (6.5), condition (2) is equivalent to $\text{kat}^\prime(\text{inv}(T)) = \mathcal{F}_{\tau}^{-1}(b') \in \mathcal{B}^{(\mu_2,\ldots,\mu_p);(w_2,\ldots,w_p)}$; by the inductive hypothesis and Proposition 6.13, this is equivalent to $\text{kat}(T) = \text{inv}(\text{kat}^\prime(\text{inv}(T)))$ being $(w_2, \ldots, w_p)$-katabolizable. Hence, noting that (1) is equivalent to $T$ having no 1’s outside its first row, we conclude that (1) and (2) are equivalent to $T$ being $w$-katabolizable. \(\square\)
Theorem 6.21. For \( w_1 = w_0 \), the DARK crystal \( B^{w_1} \) (regarded as a subset of the \( U_q(\mathfrak{g}_\ell) \)-crystal \( B^\mu \)) is a disjoint union of highest weight \( U_q(\mathfrak{g}_\ell) \)-crystals, with decomposition given by

\[
B^{w_1} = \bigcup_{U \in \text{SSYT}_\ell(\mu)} C_U, \quad \text{where } C_U = \{ b \in B^\mu \mid Q(b) = U \}. \tag{6.7}
\]

Proof. This follows from Theorems 6.4 and 6.20, using that, when \( w_1 = w_0 \), \( T \in \text{Tabloids}_\ell(\mu) \) is \( w \)-katabolizable if and only if \( P(T) = P_{w_0^{-1}}(T) \) is \( (id, w_2, \ldots, w_p) \)-katabolizable. \( \square \)

Let us now also prove Theorem 2.17: apply Theorem 6.20 with \( w = (w_0, s(\Psi)) \), then the “if and only if” statement in the proof of Theorem 6.21, and then Proposition 6.15.

7. Schur and key positivity

We connect charge to \( \hat{\mathfrak{s}_\ell} \)-weights and then combine the results of Section 6 with Corollary 2.7 and Theorem 2.11 to give several character formulas for DARK and AGD crystals; this yields our katabolism formula Theorem 2.18 upon combining with the rotation theorem. Stronger key positivity results are then obtained via the restriction Theorem 4.1.

7.1. Characters. Let \( \mathbb{Z}[P] \) denote the group ring of \( P \) with \( \mathbb{Z} \)-basis \( \{ e^\lambda \}_{\lambda \in P} \). The \( \hat{\mathfrak{s}_\ell} \)-Demazure operators are linear operators \( D_i \) on \( \mathbb{Z}[P] \) defined for each \( i \in I \) by

\[
D_i(f) = \frac{f - e^{-\alpha_i} \cdot s_i(f)}{1 - e^{-\alpha_i}},
\]

where \( s_i \) acts on \( \mathbb{Z}[P] \) by \( s_i(e^\lambda) = e^{s_i(\lambda)} \) (see §4.5). The action of \( \Sigma = \{ \tau^i \mid i \in \ell \} \) on \( P \) yields an action on \( \mathbb{Z}[P] \) given by \( \sigma(e^\lambda) = e^{\sigma(\lambda)} \) for \( \sigma \in \Sigma \). Then \( \tau \) and the \( D_i \) \( (i \in I) \) satisfy the 0-Hecke relations (4.6)–(4.10) of \( \hat{\mathfrak{h}}_\ell \) (it is well known that they satisfy (4.6), (4.7) [42, Corollary 8.2.10] and the others are easily checked). Thus, just as we discussed for \( F_w \) in §4.7, \( D_w \) makes sense for any \( w \in \hat{\mathfrak{h}}_\ell \) and \( D_w D_{w'} = D_{ww'} \) for all \( w, w' \in \hat{\mathfrak{h}}_\ell \).

The character of a subset \( S \) of a \( U_q(\hat{\mathfrak{s}_\ell}) \)-crystal is \( \text{char}(S) := \sum_{b \in S} e^{w(b)} \in \mathbb{Z}[P] \). Kashiwara [35] gave a Demazure operator formula for the character of any Demazure crystal, and Naoi extended this to encompass the action of \( \Sigma \), as follows:

Corollary 7.1 ([70, Corollary 4.6]). For any \( w \in \hat{\mathfrak{h}}_\ell \) and \( S \in \mathcal{D}(\hat{\mathfrak{s}_\ell}) \) (see Definition 2.5),

\[
\text{char}(F_w(S)) = D_w(\text{char}(S)).
\]

Set \( A = \mathbb{Z}[q^{1/2\ell}, q^{-1/2\ell}] \). Define the ring homomorphism \( \zeta \) by

\[
\zeta: A[x_{\pm 1}^\ell, \ldots, x_{\pm 1}^\ell] \to \mathbb{Z}[P], \quad x_i \mapsto e^{\omega_i - \omega_{i-1}}, \quad q^{1/2\ell} \mapsto e^{-\delta/2\ell}. \tag{7.1}
\]

It is \( S_\ell \)-equivariant (\( s_i \) acts on \( A[x_{\pm 1}^\ell, \ldots, x_{\pm 1}^\ell] \) by permuting the variables) and has kernel \( (x_1 \cdots x_\ell - 1) \). It is an extension of the map \( \zeta \) from (2.7) to a larger domain.

We wish to recover an element of \( A[x_{\pm 1}^\ell, \ldots, x_{\pm 1}^\ell] \) given its image under \( \zeta \), and this is possible if we know it to be homogenous of a given degree. Accordingly, let \( X_m \subset A[x_{\pm 1}^\ell, \ldots, x_{\pm 1}^\ell] \) denote the homogeneous component of \( x \)-degree \( m \). The restricted map \( \zeta: X_m \to \mathbb{Z}[P] \) is injective; let \( \zeta(X_m) \) denote the image and \( Z_m : \zeta(X_m) \xrightarrow{\sim} X_m \) the inverse of this restriction of \( \zeta \) (which is only a \( \mathbb{Z} \)-linear map).
Let $\mu$ be a partition and set $m = |\mu|$. Suppose $G$ is a $U_q(\widehat{\mathfrak{sl}_\ell})$-crystal such that $e^{-\mu_1\Lambda_0} \text{char}(G) \in \zeta(X_m)$ (by the proof of Theorem 7.5 below, this holds for $G = \text{AGD}(\mu; w)$, our main case of interest). We define the $x$-character of $G$ by
\[
\text{char}_{x,\mu}(G) = \sum_{g \in G} Z_m(e^{\text{wt}(g) - \mu_1\Lambda_0}) \in X_m.
\] (7.2)

In other words, if we find $f \in X_m$ such that $\zeta(f) = \text{char}(G)e^{-\mu_1\Lambda_0}$, then $f = \text{char}_{x,\mu}(G)$.

We will need two facts which relate $\pi_i$ and $D_i$, and $\Phi$ and $\tau$ via $\zeta$. First, it is straightforward to show from the $S_\ell$-equivariance of $\zeta$ that
\[
\zeta(\pi_i(f)) = D_i(\zeta(f)) \quad \text{for} \quad i \in [\ell - 1].
\] (7.3)

Second, we claim that for any $f \in X_m$,
\[
\zeta(\Phi(f)) = e^{-m\delta/\ell}\tau(\zeta(f)).
\] (7.4)

Since $\zeta$, $\tau$, and $\Phi$ are ring homomorphisms, it is enough to prove $\zeta(\Phi(x_i)) = e^{-\delta/\ell}\tau(\zeta(x_i))$. This is readily verified from the computation
\[
\tau(\zeta(x_i)) = \tau(e^{\varpi_i - \varpi_{i-1}}) = e^{\varpi_{i+1} - \varpi_{i} + \delta(m_{i+1}-m_i - (m_i-m_{i-1}))} = \begin{cases} e^{\varpi_{i+1} - \varpi_{i} + \delta/\ell} & \text{if } i \in [\ell - 1] \\ e^{\varpi_{i+1} - \varpi_{i} + \delta/\ell - \delta} & \text{if } i = \ell, \end{cases}
\]

where $m_i := \langle d, \Lambda_i \rangle$ and the last equality is by (4.4).

7.2. **Charge and $\widehat{\mathfrak{sl}_\ell}$-weights.** The pairing $\langle d, \cdot \rangle$ on $\widehat{\mathfrak{sl}_\ell}$-weights gives a statistic on $U_q(\widehat{\mathfrak{sl}_\ell})$-crystal elements, which is not available for $U'_q(\widehat{\mathfrak{sl}_\ell})$-seminormal crystals. Naoi [70] showed that the strict embedding $\Theta_\mu$ matches this statistic to energy, thereby effectively allowing the full information of $\widehat{\mathfrak{sl}_\ell}$-weights to be seen on the DARK side. Since energy on $B^\mu$ matches charge on Tabloids$_\ell(\mu) = \text{inv}(B^\mu)$ [69], the charge and $\langle d, \cdot \rangle$ statistics agree.

**Remark 7.2.** It is actually more natural to connect charge and $\langle d, \cdot \rangle$ directly as they both essentially measure the number of $\tilde{f}_0$-edges required to construct the crystal element, whereas energy is a more complicated statistic. In the interest of space, we just give the idea: for $b = \tilde{f}_{i_1}^{a_1} \cdots \tilde{f}_{i_k}^{a_k} u_A \in \mathcal{F}_{i_1} \cdots \mathcal{F}_{i_k} \{u_A\}$ with $i_j \in I$, $\langle -d, \text{wt}(b) - \text{wt}(u_A) \rangle$ is the number of $\tilde{f}_0$'s appearing in $\tilde{f}_{i_1}^{a_1} \cdots \tilde{f}_{i_k}^{a_k}$. A similar statement can be made for AGD crystals. Charge also has a similar flavor since $\tilde{f}_0$-edges are related to property (C3) below by the inv map—see [79, §4.2].

Charge is a statistic on words of partition content which is commonly defined by a circular-reading procedure (see, e.g., [81, §3.6]). We prefer to take the following theorem of Lascoux and Schützenberger as its definition.

**Theorem 7.3** ([57], see [81, Theorem 24]). Charge is the unique function from words of partition content to $\mathbb{Z}_{\geq 0}$ satisfying

(C1) **Charge of the empty word is 0.**

(C2) **For a word of partition content $\lambda$ and of the form $u = v_1^{\lambda_1}$, charge($u$) = charge($v^{-}$),**

where $v^{-}$ is obtained from $v$ by subtracting 1 from all its letters.

(C3) **For a word of partition content and of the form $u = vx$ with $x \neq 1$ a letter, charge($vx$) = charge($xv$) + 1.**
Let $U_q(\mathfrak{sl}_2) \hookrightarrow U_q(\mathfrak{sl}_2)$-semisimple crystals from Theorem 2.11. For any $b \in B^n,$

$$\zeta(q^{\text{charge}(b) + n_{\ell}(\mu)} x^{\text{content}(b)}) = e^{-\mu_1 \Lambda_0 + \text{wt}(\Theta(b \otimes u_{\mu_1})},$$  

(7.6)

where $n_{\ell}(\mu) := \frac{|\mu|(|\ell| - 2n(\mu))}{2 \ell},$ a variant of the well-known statistic $n(\mu) := \sum_{i=1}^{p} (i - 1) \mu_i.$

Proof. As $\text{wt}(b) \in P_d$ is given by (6.1), $\zeta(x^{\text{content}(b)}) = e^{\text{aff}(\text{wt}(b))}$; hence (7.5) implies (7.6).

We now prove (7.5). Set $m_i = \langle d, \lambda_i \rangle$ for $i \in I.$ Since $\Theta(b)$ commutes with the $P_d$-valued weight functions, $\text{cl}(\text{wt}(\Theta(b \otimes u_{\mu_1})) = \text{cl}(u_{\lambda_0}) + \text{wt}(b).$ Thus (7.5) is equivalent to

$$\mu_1 m_0 + \langle -d, \text{wt}(b) \otimes u_{\mu_1} \rangle - \text{charge}(b) = n_{\ell}(\mu).$$  

(7.7)

By [70, Theorem 7.1], $\langle -d, \text{wt}(b \otimes u_{\mu_1}) \rangle = D(b) + C,$ where $D(b)$ is the energy of $b$ and $C$ is a constant that depends on $\mu$ and $\ell$ but not $b.$ Further, $D(b) = \text{charge}(\text{inv}(b))$ by [69] (see also [80, Proposition 4.25]). Hence, to pin down the constant, we need only verify (7.7) for a single $b \in B^n.$ We choose $b_{hw} := F_r(\cdots F_r(F_r b_{\mu_{p}} \otimes b_{\mu_{p-1}}) \cdots \otimes b_{\mu_2}) \otimes b_{\mu_1},$ the element satisfying $\Theta(b_{hw}) = \mu_0 \otimes u_{\mu_1}$ for $\mu_{hw} := u_{\mu_0} \otimes \cdots \otimes u_{\mu_1}.$ As can be seen from the proof of [8, Theorem 3.7]. We compute

$$\mu_1 m_0 + \langle -d, \text{wt}(b_{hw}) \rangle - \text{charge}(\text{inv}(b_{hw})) = \mu_1 m_0 - \sum_{i=1}^{p} \mu_i m_i - \text{charge}(\text{inv}(b_{hw}))$$  

$$= - \sum_{i=1}^{p} \mu_i (m_i - m_{i-1}) - \text{charge}(\text{inv}(b_{hw})) = - \sum_{i=1}^{p} \mu_i \frac{2 \text{mod}_i^d(i) - 1 - \ell}{2 \ell} - \sum_{i=1}^{p} [i - 1] \mu_i$$  

$$= \frac{|\mu|(|\ell| - 2n(\mu))}{2 \ell} - \frac{1}{\ell} \sum_{i=1}^{p} (i - 1) \mu_i = n_{\ell}(\mu),$$

where $\{\text{mod}_i^d(i)\} = (i + \ell \mathbb{Z}) \cap [\ell].$ The third equality is by (4.4) and a direct computation of the charge of $\text{inv}(b_{hw}),$ the tabloid of content $\mu$ with all letters $i$ in row $\text{mod}_i^d(i).$ □

7.3. A Schur positive formula for Catalan functions: proof of Theorem 2.18.

Theorem 7.5. Let $w = (w_1, w_2, \ldots, w_p) \in (\mathcal{H}_\ell)^p$ and $\mu = (\mu_1 \geq \cdots \geq \mu_p \geq 0)$ be a partition; set $\mu^i = \mu_i - \mu_{i+1},$ where $\mu_{p+1} := 0.$ The $\mathbf{x}$-character of the crystal $\text{AGD}(\mu; w)$ agrees with the charge weighted character of the DARK crystal $B^n_w$ and these have an explicit description in terms of $\pi_i$ and $\Phi:$

$$\pi_{w_1} x_1^{\mu_1} \Phi \pi_{w_2} x_1^{\mu_2} \Phi \pi_{w_3} x_1^{\mu_3} \cdots \Phi \pi_{w_p} x_1^{\mu_p} = q^{-n_{\ell}(\mu)} \text{char}_{\mu}(\text{AGD}(\mu; w))$$  

(7.8)

$$\pi_{w_1} x_1^{\mu_1} \Phi \pi_{w_2} x_1^{\mu_2} \Phi \pi_{w_3} x_1^{\mu_3} \cdots \Phi \pi_{w_p} x_1^{\mu_p} = q^{-n_{\ell}(\mu)} \text{char}_{\mu}(\text{AGD}(\mu; w))$$  

(7.9)

where $n_{\ell}(\mu) = \frac{|\mu|(|\ell| - 2n(\mu))}{2 \ell} - \frac{1}{\ell} \sum_{i=1}^{p} (i - 1) \mu_i$ as in Corollary 7.4.
The last equality follows from (7.3) and (7.4); in particular, the constant \( n \)

Corollary 7.6.

In the case \( e \)

Proof. The first equality of (7.9) follows from Theorem 2.11 and (7.6), and the second holds by Theorem 6.20. We will establish (7.8) by proving \( e^{-\mu_1 A_0} \text{char}(\text{AGD}(\mu; w)) = e^{-\delta n_\ell(\mu)} \zeta(\pi_{w_1} x_1^{\mu_1} \Phi_{w_2} x_2^{\mu_2} \cdots \Phi_{w_p} x_p^{\mu_p}) \). By Corollaries 2.7 and 7.1,

\[
\text{char}(\text{AGD}(\mu; w)) = D_{w_1}(e^{\mu_1 A_1} \cdot \tau D_{w_2}(e^{\mu_2 A_1} \cdot \tau D_{w_3} \cdots \tau D_{w_p}(e^{\mu_p A_1})))
\]

(7.10)

(A similar character formula is proved in [70, §7] with this argument.) Using the operator identities \( e^{A_1} \tau = \tau e^{A_0} \) and \( e^{A_0} D_i = D_i e^{A_0} \) for \( i \in [\ell - 1] \), we compute

\[
e^{-\mu_1 A_0} \text{char}(\text{AGD}(\mu; w)) = e^{-\mu_1 A_0} D_{w_1}(e^{\mu_1 A_1} \cdot \tau D_{w_2}(e^{\mu_2 A_1} \cdot \tau D_{w_3} \cdots \tau D_{w_p}(e^{\mu_p A_1})))
\]

\[
= D_{w_1}(e^{\mu_1 A_1} \cdot \tau D_{w_2}(e^{\mu_2 A_1} \cdot \tau D_{w_3} \cdots \tau D_{w_p}(e^{\mu_p A_1})))
\]

\[
= D_{w_1}(e^{\mu_1 A_1} \cdot \tau D_{w_2}(e^{-\mu_2 A_0} e^{\mu_2 A_1} \cdot \tau D_{w_3} \cdots \tau D_{w_p}(e^{\mu_p A_1})))
\]

\[
= D_{w_1}(e^{\mu_1 A_1} \cdot \tau D_{w_2}(e^{\mu_2 A_1} \cdot \tau D_{w_3} \cdots \tau D_{w_p}(e^{\mu_p A_1})))
\]

\[
= D_{w_1}(e^{\mu_1 A_1} \cdot \tau D_{w_2}(e^{\mu_2 A_1} \cdot \tau D_{w_3} \cdots \tau D_{w_p}(e^{\mu_p A_1})))
\]

\[
= \cdots
\]

\[
= D_{w_1}(e^{\mu_1 A_1} \cdot \tau D_{w_2}(e^{\mu_2 A_1} \cdot \tau D_{w_3} \cdots \tau D_{w_p}(e^{\mu_p A_1})))
\]

\[
= e^{-\delta n_\ell(\mu)} \zeta(\pi_{w_1} x_1^{\mu_1} \Phi_{w_2} x_2^{\mu_2} \cdots \Phi_{w_p} x_p^{\mu_p}).
\]

The last equality follows from (7.3) and (7.4); in particular, the constant \( n_\ell(\mu) \) appears since, as we pull \( \zeta \) to the right through the operators, we pick up a factor \( e^{-\frac{\delta}{\ell} \sum_{i=1}^{p} (i-1) \mu_i} \) for converting \( \Phi \)'s to \( \tau \)'s and a factor \( e^{\delta |\mu|} \frac{1}{\ell!} \) for converting multiplication by \( x_1 \) to multiplication by \( e^{A_1 - A_0} \) since \( \zeta(x_1) = e^{w_1} = e^{\frac{\delta}{\ell} \frac{1}{\ell!}} e^{A_1 - A_0} \) by (4.4).

**Corollary 7.6.** In the case \( w_1 = w_0 \) (the longest element in \( H_\ell \)), the characters in Theorem 7.5 have the following Schur positive expansion:

\[
\pi_{w_1} x_1^{\mu_1} \Phi_{w_2} x_2^{\mu_2} \Phi_{w_3} x_3^{\mu_3} \cdots \Phi_{w_p} x_p^{\mu_p} = q^{-n_\ell(\mu)} \text{char}_{x,\mu}(\text{AGD}(\mu; w))
\]

\[
= \sum_{b \in B^{\mu}|w}} q^{\text{charge}(\text{inv}(b))} x^{\text{content}(b)} = \sum_{U \in \text{SYT}_\ell(\mu), U \text{ is (id, } w_2, \ldots, w_p-) \text{-katabolizable}} q^{\text{charge}(U)} s_{\text{shape}(U)}(x).
\]

**Proof.** Combine Theorems 6.21 and 7.5, noting that each component \( C_U \) of the \( U_{q}(g_\ell) \)-crystal \( B^{\mu|w} \) contributes \( q^{\text{charge}(U)} \) times \( \sum_{b \in C_U} x^{\text{content}(b)} = \sum_{U \in \text{SYT}_\ell(\mu)} \sum_{b \in B^{\mu|w}_{\text{shape}(U)}} x^{\text{wt}(b)} = s_{\text{shape}(U)}(x) \)

**Proposition 7.7.** When \( \Psi \) is the parabolic root ideal \( \Delta(\eta) \) for some composition \( \eta \) of \( \ell \) (see (2.12)), a tableau \( T \) of partition content \( \mu \) is \( n(\Psi) \)-katabolizable if and only if it is \( R(\eta, \mu) \)-katabolizable in the sense of [81, §3.7].

**Proof.** Checking whether \( T \) is \( n(\Psi) \)-katabolizable begins with the computation \( U = P_{1, \ell} \circ \text{kat} \cdots P_{n_1-1, \ell} \circ \text{kat} \circ P_{n_1, \ell} \circ \text{kat}(T) \). The key observation is that each row \( T^1, T^2, \ldots, T^m \) of \( T \) is never touched by the column insertions until it is rotated to become the new \( \ell \)-th row. Hence the computation of \( U \) amounts to the following: check whether \( T^i \) contains \( \mu_i \) 1's, remove these 1's, then column insert the result into \( T^{n_1+1, \ell} \) to obtain a new tableau \( V \),
then check whether \( T^2 \) contains \( \mu_2 \) 2’s, remove these 2’s, column insert the result into \( V \), and so on. These checks are equivalent to checking whether \( T \) contains the superstandard tableau \( Z \) of shape \((\mu_1, \ldots, \mu_m)\). Thus, \( T \) is not rejected in this computation if and only if \( T \) contains \( Z \), and if so, \( U \) is obtained by column inserting \( T^{[m]} \setminus Z \) into \( T^{[m+1, \ell]} \) one row at a time, which is the same as the rectification of the skew tableau formed by placing \( T^{[m]} \setminus Z \) and \( T^{[m+1, \ell]} \) catty-corner. This is exactly the first step in the katabolism algorithm of [81]. Continuing in this way with \( \eta_2, \eta_3, \ldots \) gives the result. \( \square \)

7.4. Key positivity. We generalize the results above to key positive formulas for characters of AGD and DARK crystals and tame nonsymmetric Catalan functions. To do this, we address the algorithmic problem of obtaining explicit key expansions for characters of \( U_q(\mathfrak{gl}_\ell) \)-Demazure crystals; some of this material, in particular Proposition 7.9, is similar in spirit to [5, §4].

Let \( B \) be a \( U_q(\mathfrak{gl}_\ell) \)-crystal. The weight function takes values in \( \mathbb{Z}^\ell \) and we write \( wt(b) = (wt_1(b), \ldots, wt_\ell(b)) \) for the entries of \( wt(b) \). The crystal reflection operators \( S_i : B \to B, i \in [\ell - 1] \), are given by

\[
S_i(b) = \begin{cases} 
\tilde{e}_i^{wt_i(b)-wt_{i+1}(b)}(b) & \text{if } wt_i(b) \geq wt_{i+1}(b), \\
\tilde{e}_i^{wt_i(b)+wt_{i+1}(b)}(b) & \text{if } wt_i(b) \leq wt_{i+1}(b).
\end{cases}
\]

Note that \( s_i(wt(b)) = wt(S_i(b)) \). The operators \( S_i \) were first studied by Lascoux and Schützenberger [57], and later generalized by Kashiwara [36]. They satisfy the braid relations and therefore generate an action of \( S_\ell \) on \( B \). For \( 1 \leq i < j \leq \ell \), let \( s_{ij} = s_is_{i+1}\cdots s_{j-2}s_{j-1}s_{j-2}\cdots s_i \in S_\ell \) denote the transposition swapping \( i \) and \( j \), and \( S_\ell^{ij} = S_iS_{i+1}\cdots S_{j-2}S_{j-1}S_{j-2}\cdots S_i \) the corresponding reflection operator.

We define Bruhat order on \( \mathbb{Z}^\ell \) by \( \alpha < \beta \) if and only if \( \alpha + = \beta + \) and \( p(\alpha) < p(\beta) \) in Bruhat order on \( S_\ell \), where \( \alpha + \) denotes the weakly decreasing rearrangement of \( \alpha \) and \( p(\alpha) \) the shortest element such that \( p(\alpha)\alpha + = \alpha \).

**Proposition 7.8.** The relation \( \beta > \alpha \) is a covering relation in Bruhat order on \( \mathbb{Z}^\ell \) if and only if there exist \( 1 \leq i < k \leq \ell \) such that \( \alpha = s_{ik}\beta \) with \( \alpha_i > \alpha_k \), and \( \alpha_j \notin [\alpha_i, \alpha_k] \) for all \( j \in [i + 1, k - 1] \).

**Proof.** For permutations \( \alpha \) and \( \beta \), this is a well-known combinatorial description of the Bruhat order covering relations of \( S_\ell \) (see, e.g., [7, Lemma 2.1.4]). The general case can be deduced from this one by a standardization argument and the fact that any covering relation in the Bruhat order poset restricted to minimal coset representatives is actually a covering relation in the full Bruhat poset (by, e.g., [7, Theorem 2.5.5]). \( \square \)

For example, \( \beta = 32812852 > 52812832 = \alpha \) is a covering relation and \( \alpha = s_{17}\beta \).

The next proposition is motivated by the following algorithmic problem: suppose we have access to the elements of a \( U_q(\mathfrak{gl}_\ell) \)-Demazure crystal \( G \) and want to determine the \( \gamma \in \mathbb{Z}^\ell \) for which \( G = BD(\gamma) \) (see §4.8 for the definition of \( BD(\gamma) \)).

**Proposition 7.9.** Let \( G \) be a \( U_q(\mathfrak{gl}_\ell) \)-Demazure crystal. There is a unique element \( u_{lw} \in G \) such that, setting \( \gamma = wt(u_{lw}) \), (1) \( \gamma^+ \) is the highest weight of \( G \), and (2) \( S_{ij}(u_{lw}) \notin G \) for all covering relations \( \gamma < s_{ij}\gamma \) in Bruhat order on \( \mathbb{Z}^\ell \). Moreover, \( G = BD(\gamma) \).
Proof. Consider a highest weight $U_q(\mathfrak{g}_\ell)$-crystal $B^\mu(\nu)$. For each weight $\alpha$ in the orbit $S_\ell \cdot \nu$, there is a unique element $u_\alpha \in B^\mu(\nu)$ of weight $\alpha$; it belongs to $BD(\beta)$, $\beta \in S_\ell \cdot \nu$, if and only if $\alpha \leq \beta$ in Bruhat order on $\mathbb{Z}_\ell$. It follows that if $G = BD(\tilde{\gamma})$, then $u_\gamma \in B^\mu(\tilde{\gamma}_+)$ is the unique element $u_{tw} \in G$ satisfying (1) and (2), and $G = BD(\text{wt}(u_{tw}))$.

For a tabloid $T \in \text{Tabloids}_\mathbb{Z}(\mu)$ and $i \in [\ell - 1]$, define $S'_i := \text{inv} \circ S_i \circ \text{inv}(T)$ and $S'_{ij} = \text{inv} \circ S_{ij} \circ \text{inv}(T)$. In fact, we only need this action on the set of row frank tabloids:

RowFrank$_\mathbb{Z}(\mu) := \{ T \in \text{Tabloids}_\mathbb{Z}(\mu) \mid \text{shape}(T) \text{ is a rearrangement of shape}(P(T)) \}$,

which is also the set of inverses of the extremal weight elements of the crystal $B^\mu$. Since shape($S'_i(T)$) = $s_i(\text{shape}(T))$ for any $T \in \text{RowFrank}_\mathbb{Z}(\mu)$, the $S'_i$ preserve the set RowFrank$_\mathbb{Z}(\mu)$. This also gives a simple description of $S'_{ij}(T)$ for $T \in \text{RowFrank}_\mathbb{Z}(\mu)$: $S'_{ij}(T)$ is the unique row frank tabloid Knuth equivalent to $T$ with shape obtained from shape($T$) by exchanging the $i$-th and $j$-th parts.

**Definition 7.10.** A tabloid $T \in \text{RowFrank}_\mathbb{Z}(\mu)$ is extreme $w$-katabolizable if $T$ is $w$-katabolizable and $S'_{ij}(T)$ is not $w$-katabolizable for all $i < j$ such that shape($T$) < shape($S_{ij}(T)$) is a covering relation in Bruhat order on $\mathbb{Z}_\ell$.

**Theorem 7.11.** The DARK crystal $B^{\mu,w}$ is isomorphic to a disjoint union of $U_q(\mathfrak{g}_\ell)$-Demazure crystals, with decomposition given by

$$B^{\mu,w} = \bigcup_{T \in \text{RowFrank}_\mathbb{Z}(\mu), \text{T is extreme w-katabolizable}} \tilde{C}_T,$$

where $\tilde{C}_T = \{ b \in B^{\mu,w} \mid Q(b) = P(T) \} \cong BD(\text{shape}(T))$.

**Proof.** By Corollary 2.7 and Theorem 4.1, the $U_q(\mathfrak{g}_\ell)$-restriction of AGD($\mu; w$) is isomorphic to a disjoint union of $U_q(\mathfrak{g}_\ell)$-Demazure crystals. So the same is true of $B^{\mu,w} \otimes u_{\mu_1 \Lambda_0}$ (by Theorem 2.11) and therefore $B^{\mu,w}$ as well. Hence by Remark 4.2, $B^{\mu,w}$ is isomorphic to a disjoint union of $U_q(\mathfrak{g}_\ell)$-Demazure crystals; this decomposition can be written as $B^{\mu,w} = \bigsqcup C_U \cap B^{\mu,w}$, where $C_U$ ranges over the $U_q(\mathfrak{g}_\ell)$-components of $F_{w_0} B^{\mu,w}$ (see Theorem 6.21). Then by Proposition 7.9 and Theorem 6.20, each set $\text{inv}(C_U \cap B^{\mu,w})$ contains a unique $T \in \text{RowFrank}_\mathbb{Z}(\mu)$ which is extreme $w$-katabolizable, and $C_U \cap B^{\mu,w} = \{ b \in B^{\mu,w} \mid Q(b) = U \} = \tilde{C}_T \cong BD(\text{shape}(T))$.

**Corollary 7.12.** The characters in Theorem 7.5 are key positive with key expansion

$$\pi_{w_1} x_1^\mu_1 \Phi \pi_{w_2} x_1^\mu_2 \Phi \pi_{w_3} x_1^\mu_3 \cdots \Phi \pi_{w_p} x_1^{\mu_p} = q^{-n(\mu)} \text{char}_{\mathfrak{g}_\ell}(\text{AGD}(\mu; w)) = \sum_{b \in B^{\mu,w}} q^{\text{charge}(\text{inv}(b))} x^\text{content}(b) \sum_{T \in \text{RowFrank}_\mathbb{Z}(\mu), T \text{ is extreme w-katabolizable}} q^{\text{charge}(T)} K_{\text{shape}(T)}(x).$$

**Proof.** Combine Theorems 7.11 and 7.5; each $U_q(\mathfrak{g}_\ell)$-Demazure crystal $\tilde{C}_T$ contributes

$$\sum_{b \in \tilde{C}_T} q^{\text{charge}(T)} x^\text{content}(b) = \sum_{b \in BD(\text{shape}(T))} q^{\text{charge}(T)} x^\text{wt}(b) = q^{\text{charge}(T)} K_{\text{shape}(T)}(x)$$

to the left side of (7.9), where we have used Proposition 4.8 for the second equality.

Combining Corollary 7.12 and Theorem 2.3 yields a positive combinatorial formula for the key expansions of tame nonsymmetric Catalan functions, generalizing Theorem 2.18:
Corollary 7.13. Let \((\Psi, \mu, w)\) be a tame labeled root ideal of length \(\ell\) with partition \(\mu\). Set \(w = (w, s(\Psi)) \in (\mathcal{H}_\ell)^\ell\) with \(s(\Psi)\) as in (2.8). The associated nonsymmetric Catalan function has the key positive expansion

\[
H(\Psi; \mu; w)(x; q) = \sum_{T \in \text{RowFrank}_\ell(\mu)} q^{\text{charge}(T)} \kappa_{\text{shape}(T)}(x)
\]  

and is the character of a AGD crystal and DARK crystal:

\[
H(\Psi; \mu; w)(x; q) = q^{-\nu(\mu)} \text{char}_{x^\mu}(AGD(\mu; w)) = \sum_{b \in B^{\mu, w}} q^{\text{charge}(\text{inv}(b))} x^{\text{content}(b)}.
\]

See the last three lines of Figure 1 (§2.7). The bold tabloids in Figure 2 are the extreme \(v\)-katabolizable tabloids, for \(v = (s_1 s_2 s_1, s_2 s_1, s_2 s_1)\) (left), \(v = (s_2, s_2 s_1, s_2 s_1)\) (right); reading off their shapes and charges yields the rightmost two key expansions in Figure 1.

Example 7.14. Let \(\ell = 5\), \(\mu = 22211\), and \(\Psi\) be the root ideal defined by \(n(\Psi) = (2, 2, 2, 2)\). Let \(w = s_3 s_4 s_3\). Then \(w = (w, s(\Psi)) = (s_3 s_4 s_3, s_4 s_3 s_2, s_4 s_3 s_2, s_4 s_3 s_2, s_4 s_3 s_2)\). Figure 4 (right) depicts the set of \(T\) in \(\text{RowFrank}_\ell(\mu)\) such that \(T\) is extreme \(w\)-katabolizable. By (7.11), reading off their shapes and charges yields the key positive expansion

\[
H(\Psi; \mu; w) = \kappa_{s_22111} + q \kappa_{32111} + q^2 \kappa_{22013} + q^2 \kappa_{22013} + q^3 \kappa_{33011} + q^2 \kappa_{33011} + q^2 \kappa_{23003} + q^2 \kappa_{42011} + q^3 \kappa_{42011} + q^3 \kappa_{43001} + q^3 \kappa_{43002} + q^3 \kappa_{33002} + q^4 \kappa_{43001} + q^4 \kappa_{52001} + q^5 \kappa_{53000}.
\]

On the left of Figure 4 are the inverses of the \(U_q(\mathfrak{gl}_\ell)\)-highest weight elements of \(B^{\mu, w}\) obtained by computing \(P(T)\) of the tabloids on the right. This is also the set of \(U \in \text{SSYT}_\ell(\mu)\) which are \((\text{id}, s(\Psi))\)-katabolizable (= \(n(\Psi)\)-katabolizable), providing an example of Theorem 2.18 and Corollary 7.6 as well: reading off their shapes and charges yields the following Schur positive expression for \(H(\Psi; \mu; w_0) = \sum_{b \in B^{\mu, (w_0, s(\Psi))}} q^{\text{charge}(\text{inv}(b))} x^{\text{content}(b)}\).

\[
H(\Psi; \mu; w_0) = s_{22111} + q s_{32111} + q s_{32122} + q^2 s_{33111} + q^2 s_{32211} + q^2 s_{33111} + q^3 s_{33011} + q^2 s_{4211} + q^3 s_{4211} + q^3 s_{431} + q^3 s_{422} + q^3 s_{332} + q^3 s_{431} + q^4 \kappa_{52001} + q^5 \kappa_{53000}.
\]

Let us check that the tabloid \(T = \begin{array}{cccccc}
1 & 4 & 3 & 1 & 1 & 1 \\
2 & 2 & 2 & 1 & 1 & 1 \\
2 & 2 & 2 & 1 & 1 & 1 \\
\end{array}\) is extreme \(w\)-katabolizable. First, the following computation shows it is \(w\)-katabolizable:
We must also show that $S_{ij}'(T)$ is not $\mathbf{w}$-katabolizable for all covering relations $\text{shape}(T) < s_{ij}(\text{shape}(T))$. We have $\text{shape}(T) = 42011$, and there are three covering relations corresponding to $(i,j) = (1,2), (2,3), \text{and} (2,4)$.

8. Consequences for $t = 0$ nonsymmetric Macdonald polynomials

We show that the $t = 0$ specialized nonsymmetric Macdonald polynomials are characters of AGD crystals and equal to certain nonsymmetric Catalan functions. We thus obtain a key positive formula for these polynomials as a special case of Corollary 7.12.
The Knop-Sahi recurrence [41, 75] determines the nonsymmetric Macdonald polynomials $E_\alpha(x; q, t) = E_\alpha(x_1, \ldots, x_\ell; q, t)$ for all weak compositions $\alpha \in \mathbb{Z}_+^\ell$. At $t = 0$, the recurrence becomes

$$E_{(0, \ldots, 0)}(x; q, 0) = 1, \quad \text{(8.1)}$$

$$E_{s_i \alpha}(x; q, 0) = \pi_i(E_{\alpha}(x; q, 0)), \quad \text{(8.2)}$$

$$E_{(\alpha_{\ell+1}, \alpha_1, \ldots, \alpha_{\ell-1})}(x; q, 0) = q^{\alpha_i}x_i E_{\alpha}(x_2, \ldots, x_\ell, x_1/q; q, 0), \quad \text{(8.3)}$$

which determines the specializations $E_\alpha(x; q, 0)$. We have adopted the notation of [26, Equations (40)–(42)], except that in (8.2) we have used the action of $H_\ell$ on $\mathbb{Z}_+^\ell$ from (4.11) to put what are often two equations into one. For this paper, it is more convenient to work with a renormalization of the $E_\alpha(x; q, 0)$, denoted $\tilde{E}_\alpha = \tilde{E}_\alpha(x; q)$ and defined by

$$\tilde{E}_{(0, \ldots, 0)} = 1, \quad \text{(8.4)}$$

$$\tilde{E}_{s_i \alpha} = \pi_i(\tilde{E}_\alpha), \quad \text{(8.5)}$$

$$\tilde{E}_{(\alpha_{\ell+1}, \alpha_1, \ldots, \alpha_{\ell-1})} = x_1 \tilde{E}_\alpha(x_2, \ldots, x_\ell, qx_1) = x_1 \Phi(\tilde{E}_\alpha), \quad \text{(8.6)}$$

The two versions are related by $E_\alpha(x; q, 0) = q^{\sum (\binom{n}{2})} \tilde{E}_\alpha(x; q^{-1})$; note that the exponent of $q$ here is also $n(\eta) = \sum (i-1)\eta_i$ for $\eta = (\alpha^+)'$ the conjugate partition of $\alpha^+$ (recall that $\alpha^+$ denotes the weakly decreasing rearrangement of $\alpha$). In addition, our notation $E_\alpha(x; q, t)$ agrees with that of [5, 24, 26], while the version used by Sanderson [76], call it $E_{\alpha}^S$, is related by $E_{\alpha}^S(x_1, \ldots, x_\ell; q, t) = E_{(\alpha_{\ell-1}, \alpha_1, \ldots, \alpha_{\ell-1})}(x_1, \ldots, x_\ell; q, t)$.

We suggest that on a first reading of this section, the reader focus on the case $|\alpha| = \ell$, as it captures the main ideas but with fewer technical details.

### 8.1. Sanderson’s theorem and key positivity.

Recall from §4.5 that $\tilde{S}_\ell \subset GL(\mathfrak{h}^*)$. Set $y_1 = \tau s_{\ell-1} \cdots s_1$ and $y_i = s_{i-1} \cdots s_1 y_1 s_1 \cdots s_{i-1}$ for $i = 2, \ldots, \ell$. These elements commute pairwise and satisfy only one additional relation $y_1 \cdots y_\ell = id$; hence they generate a subgroup of translations $T$, with $T \overset{\cong}{\to} \mathbb{Z}^\ell/\mathbb{Z}(1, \ldots, 1) \overset{\cong}{\to} \bigoplus_{i \in I} \mathbb{Z} \omega_i$ via $y_1 \mapsto e_1 \mapsto \omega_i - \omega_{i-1}$. Write $y^\lambda \in T$ for the element mapping to $\lambda \in \bigoplus_{i \in I} \mathbb{Z} \omega_i$, so that $y^{\omega_i} = y_1 \cdots y_i$. These satisfy $y^\lambda y^\mu = y^{\lambda + \mu}$ and $wy^{\lambda - w^{-1}} = y^{w(\lambda)}$ for $\lambda, \mu \in \bigoplus_{i \in I} \mathbb{Z} \omega_i$ and $w \in S_\ell$. Hence $\tilde{S}_\ell = S_\ell \times T$. One can check that $y^{\lambda} \in GL(\mathfrak{h}^*)$ is the same as the $t_\lambda$ defined in [33, Equation 6.5.2], which is one way to verify the above facts about the $y_i$ and $T$ and matches our notation with [33, 70].

**Lemma 8.1.** View a translation $y^\lambda \in \tilde{S}_\ell$ as an element of the 0-Hecke monoid $\tilde{H}_\ell$ by taking any reduced expression for it. Let $d, d' \in [\ell]$. The following hold in $\tilde{H}_\ell$:

(i) $s_i$ commutes with $\tau s(d)$ for $0 \leq i \leq \ell - 1$.

(ii) $(\tau s(d))^d$ is a reduced expression for $y^{\omega_d}$ in $\tilde{S}_\ell$, and thus $y^{\omega_d} = (\tau s(d))^d$ in $\tilde{H}_\ell$.

(iii) For weights $\lambda, \mu \in \sum_{i \in I} \mathbb{Z} \omega_i$, $y^\lambda y^\mu = y^{\lambda + \mu} = y^\mu y^\lambda$.

(iv) $(\tau s(d))^d$ commutes with $(\tau s(d'))^{d'}$.

**Proof.** For (i), we compute using the relations (4.6)–(4.8):

$$s_i(\tau s_{\ell-1} \cdots s_d) = \tau s_{\ell-1} \cdots s_d = \tau s_{\ell-1} \cdots s_{i+1} s_{i-1} s_i s_{i-1} s_{i-2} \cdots s_d$$

$$= \tau s_{\ell-1} \cdots s_{i+1} s_i s_{i-1} s_{i-2} \cdots s_d = (\tau s_{\ell} \cdots s_d) s_i.$$
Statement (ii) can be proved using the description of $\tilde{S}_2$ as certain permutations of $\mathbb{Z}$; see, for instance, (15), (18), (19), and Proposition 4.1 of [9]. For $\lambda, \mu \in \sum_{i \in \mathbb{Z}} \mathbb{Z}_{\geq 0} \omega_i$, \length(y^\lambda) + \length(y^\mu) = \length(y^{\lambda+\mu})$ (see, e.g., [26, §4.1]), which gives (iii). Statement (iv) is immediate from (ii) and (iii).

We will need the observation that affine generalized Demazure crystals $\text{AGD}(\mu; \mathbf{w})$ for constant $\mu$ are just affine Demazure crystals.

**Proposition 8.2.** Suppose $\mu = (a^m, 0^{p-m})$ for $a \in \mathbb{Z}_{\geq 0}$ and $\mathbf{w} = (w_1, w_2, \ldots, w_p) \in (\mathcal{H}_t)^p$. Then $\text{AGD}(\mu; \mathbf{w}) = \mathcal{F}_{w_1 \tau w_2 \cdots \tau w_m} \{u_{\mathbf{A} \lambda} \} = B_{w_1 \tau w_2 \cdots \tau w_m}(a \Lambda_1) \subset B(a \Lambda_m)$. Further, $B_{w_1 \tau w_2 \cdots \tau w_m}(a \Lambda_1) = B_{w_1 \tau w_2 \cdots \tau w_m}(a \Lambda_0)$ for any $w \in \mathcal{H}_t$.

**Proof.** As $\mu^i = 0$ for $i \neq m$, the first statement is immediate from the definition of $\text{AGD}(\mu; \mathbf{w})$ in (2.6). The second follows from the fact that $\tilde{f}_i u_{\mathbf{A} \lambda} = 0$ for $i \in [\ell - 1]$. □

Recall from (7.2) the definition of the $x$-character of a crystal. The next result is partially a restatement of Sanderson’s theorem [76] (specifically, $\tilde{E}_\alpha = q^{\frac{p(p-\ell)}{2\ell}} \text{char}_{x, \mu}(B_v(\Lambda_0))$). However, we now have the advantage of seeing it as part of the more general Theorem 7.5 and can make it combinatorially explicit in a way which encompasses earlier work of Lascoux [53] and Shimozono-Weyman [81] on cocharge Kostka-Foulkes polynomials.

**Theorem 8.3.** The $t = 0$ nonsymmetric Macdonald polynomials are $x$-characters of affine Demazure crystals: let $\alpha \in \mathbb{Z}^\ell_{\geq 0}$ and $\eta = (\eta_1, \ldots, \eta_k) = (\alpha^+)'$ be the conjugate of $\alpha^+$. Let $z \in \mathcal{H}_t$ be any element satisfying $z\alpha^+ = \alpha$. Set $p = |\alpha|$ and $\mu = 1^p$. Then

$$\tilde{E}_\alpha(x; q) = \pi_z(x_1 \Phi \pi_{s(\eta_k)})^{\eta_k} \cdots (x_1 \Phi \pi_{s(\eta_1)})^{\eta_1} \cdot 1$$

$$= q^{\frac{p(p-\ell)}{2\ell}} \text{char}_{x, \mu}(B_v(\Lambda_0)) = \sum_{b \in B_{\mathbf{w}}} q^{\text{charge}(\text{inv}(b))} x^\text{content}(b),$$

(8.7)

where $v = z(\tau \pi_{s(\eta_k)})^{\eta_k} (\tau \pi_{s(\eta_{k-1})})^{\eta_{k-1}} \cdots (\tau \pi_{s(\eta_1)})^{\eta_1} = z y^{\omega_{\eta_1} + \cdots + \omega_{\eta_k}} \in \tilde{\mathcal{H}}_t$, and

$$\mathbf{w} = (z(s(\eta_k), \ldots, s(\eta_1)), s(\eta_2), \ldots, s(\eta_2), s(\eta_1), \ldots, s(\eta_1)).$$

(8.8)

**Proof.** First, using (8.5), we obtain $\tilde{E}_\alpha = \pi_z \tilde{E}_{\alpha^+}$. Let $\beta = \alpha^+ - \epsilon_{\eta_k}$ be the result of subtracting 1 from the rightmost occurrence of the largest part of $\alpha^+$; by (8.5)–(8.6), $\tilde{E}_{\alpha^+} = x_1 \Phi \pi_{s(d)}(\tilde{E}_\beta)$ for any $d$ such that $\beta_d = (\alpha^+)_1 - 1$, which is equivalent to $\eta_k \leq d \leq \eta_{k-1}$. The same argument shows that $\tilde{E}_\beta = x_1 \Phi \pi_{s(d')}(\tilde{E}_{\beta - \epsilon_{\eta_{k-1}}})$ for any $\eta_{k-1} \leq d' \leq \eta_{k-1}$. Repeating this $\eta_k - 2$ more times, we obtain $\tilde{E}_{\alpha^+} = (x_1 \Phi \pi_{s(\eta_k)})^{\eta_k} (\tilde{E}_{\alpha^+ - (\epsilon_1 + \cdots + \epsilon_{\eta_k})})$.

Continuing in this way we obtain (8.7).

By Theorem 7.5, the right side of (8.7) is equal to $\sum_{b \in B_{\mathbf{w}}} q^{\text{charge}(\text{inv}(b))} x^\text{content}(b) = q^{\frac{p(p-\ell)}{2\ell}} \text{char}_{x, \mu}(\text{AGD}(\mu; \mathbf{w}))$, and this is also equal to $q^{\frac{p(p-\ell)}{2\ell}} \text{char}_{x, \mu}(B_v(\Lambda_0))$ by Proposition 8.2. Finally, the two descriptions of $v$ are equal by Lemma 8.1 (ii)–(iii). □

Combining (8.7) with Corollary 7.12 we obtain
Corollary 8.4. Maintain the notation of Theorem 8.3. The $t = 0$ nonsymmetric Macdonald polynomials are key positive with key expansion given by
\[
q^{\sum_i \binom{a}{i}} E_\alpha(x; q^{-1}, 0) = \tilde{E}_\alpha(x; q) = \sum_{T \in \text{RowFrank}_k(\mu)} q^{\text{charge}(T)} k_{\text{shape}(T)}(x). \tag{8.9}
\]

Example 8.5. We illustrate Corollary 8.4 for $\ell = 4, \alpha = 0302$. We have $\alpha^+ = 3200, \eta = (\alpha^+)' = 221$, $\mu = 15$, and $w = (s_1 s_3 s_2, s_3 s_2 s_1, s_3 s_5, s_3 s_2, s_3 s_2)$.

Here are the corresponding inverses of highest weight elements obtained by computing $P(T)$ of these tabloids. This is also the subset of tableaux in the Lascoux/Shimozono-Weyman formula for $\omega H_\eta$ with at most $\ell$ rows (see Theorems 8.7 and 8.15). Taking $\sum_U q^{\text{charge}(U)} s_{\text{shape}(U)}$ over these tableaux gives the symmetrization of $\tilde{E}_{0302}$.

Remark 8.6. Another key positive formula for the $t = 0$ nonsymmetric Macdonald polynomials was given by Assaf and Gonzalez in [5, 6]. Their approach also uses crystals but their indexing combinatorial objects are rather different—compare Example 8.5 with [5, Figure 31]. An interesting problem is to find an explicit bijection between the two objects.

Let us now explain how Corollary 8.4 is a nonsymmetric generalization of Lascoux’s formula for the cocharge Kostka-Foulkes polynomials $\bar{K}_{\mu}(q)$. For partition $\mu$, let $\bar{H}_\mu(x_1, x_2, \ldots; q)$ be the cocharge variant modified Hall-Littlewood polynomial; it equals $q^{\mu(\mu)} q'_\mu(x_1, x_2, \ldots; q^{-1})$ in the notation of [66, p. 234], specializes to the homogeneous symmetric function $h_\mu$ at $q = 1$, and the coefficient of $s_\mu$ is $q^{\mu(\mu)}$. Lascoux [53] gave a formula for $\bar{H}_\mu$ in terms of a function katype from standard tableaux to partitions (see [81, §4.1]); this version of katabolism was shown [81, §4] to agree with a special case of the Shimozono-Weyman version despite its somewhat different looking definition. We assemble these results as follows:

Theorem 8.7 (Shimozono-Weyman [81, §4], Lascoux [53]). Let $\eta$ be a partition of $\ell$. Recall that $\Delta(\eta)$ is the parabolic root ideal with blocks given by $\eta$ (see (2.12)). Then
\[
\omega H_\eta = \sum_{U} q^{\text{charge}(U)} s_{\text{shape}(U)}(x) = H(\Delta(\eta); 1^\ell; w_0)(x; q), \tag{8.10}
\]

where the sum is over the set of standard tableaux $U$ which are $R(\eta, 1^\ell)$-katabolizable in the sense of [81, §3.7], and, moreover, this set equals $\{U \mid \text{katype}(U^t) \supseteq \eta\}$, where $U^t$ denotes the transpose of $U$, and $\supseteq$ denotes dominance order on partitions. Here, $x = (x_1, \ldots, x_\ell)$.
and \( \omega \) denotes the \( \mathbb{Z}[q] \)-algebra homomorphism from symmetric functions in \( x_1, x_2, \ldots \) to \( \mathbb{Z}[q][x]^S \) which satisfies \( \omega(s_\lambda(x_1, x_2, \ldots)) = s_\lambda(x) \).

We have not defined either notion of katabolism appearing here, but by Proposition 7.7, \( R(\eta, 1^\ell) \)-katabolizability agrees with \( n(\Delta(\eta)) \)-katabolizability of standard tableaux.

For \( \ell \geq |\eta| \), define \( \Delta_\ell(\eta) \subset \Delta_\ell^{+} \) to be the root ideal \( \Delta(\eta) \cup \{(i, j) \in \Delta_\ell^{+} \mid j > |\eta|\} \) (this is just a convenient way to extend \( \Delta(\eta) \) to length \( \ell \)—see Proposition 5.5 (v)). Our key positive formula (8.9) “symmetrizes” to the Lascou/Shimozono-Weyman formula (8.10) in the following sense:

**Theorem 8.8.** Maintain the notation of Theorem 8.3; also set \( m \leq \ell \). Let \( \text{SYT}^m = \text{SSYT}_\ell(\mu) \), the standard Young tableaux with \( m \) boxes. Then

\[
\pi_{w_0} \tilde{E}_\alpha(x; q) = H(\Delta(\eta); \mu; w_0)(x; q) = \sum_{U \in \text{SYT}^m} q^{\text{charge}(U)} s_{\text{shape}(U)}(x). \tag{8.11}
\]

Moreover, \( \mathcal{F}_{w_0} \mathcal{B}^{\mu; \omega} = \mathcal{B}^{\mu; (w_0, s(\Delta_\ell(\eta)))} \) as \( U_q(\mathfrak{gl}_\ell) \)-crystals, and so

\[
\{ P(T) \mid T \in \text{RowFrank}_\ell(\mu) \text{ is extreme } \omega-\text{katabolizable} \} = \{ U \in \text{SYT}^m \mid U \text{ is } n(\Delta_\ell(\eta))-\text{katabolizable} \} = \{ U \in \text{SYT}^m \mid \text{kattype}(U^\ell) \geq \eta \}. \tag{8.12}
\]

The proof is given in §8.3, along with a similar result for \( m > \ell \).

### 8.2. Connection to nonsymmetric Catalan functions.

For \( \alpha \in \mathbb{Z}_{\geq 0}^\ell \), define \( \tilde{p}(\alpha) \in \mathcal{H}_\ell \) to be the longest element such that \( \tilde{p}(\alpha)\alpha^{\ell} = \alpha \). This choice of \( z \) in Theorem 8.3 will be important below.

We now show that the \( \tilde{E}_\alpha \) can be realized as certain tame nonsymmetric Catalan functions. Note that this is not immediate from Theorem 8.3 as typically \( \eta_k + 1 \) does not lie in the right descent set of \( \tilde{p}(\alpha) \) and so (8.7) does not match a tame nonsymmetric Catalan function via Theorem 2.3. However, there is a way to rewrite (8.7) which does the job. This adds to the list of interesting functions which are encompassed in the nonsymmetric Catalan functions, proves that the \( \tilde{E}_\alpha \) are Euler characteristics of vector bundles on Schubert varieties (see Theorem 2.20), and is important in the proofs of Theorems 8.8 and 8.15.

**Definition 8.9.** For a partition \( \eta = (\eta_1, \ldots, \eta_k) \) of \( m \), let \( \Delta^\prime(\eta) \subset \Delta_\ell^+ \) be the root ideal determined by

\[
n(\Delta^\prime(\eta)) = ((\eta_1)^{\eta_2}, \eta_1, \eta_1 - 1, \eta_1 - 2, \ldots, \eta_2 + 1, (\eta_2)^{\eta_3}, \eta_2, \eta_2 - 1, \eta_2 - 2, \ldots, \eta_3 + 1, \\
\cdots (\eta_{k-1})^{\eta_k}, \eta_{k-1}, \eta_{k-1} - 1, \ldots, \eta_k + 1, \eta_k, \eta_k - 1, \ldots, 2),
\]

where \((\eta_1)^{\eta_2}\) indicates that \( \eta_1 \) appears in the list \( \eta_2 \) times, and similarly for \((\eta_2)^{\eta_3}\), etc. Informally, \( \Delta^\prime(\eta) \) is obtained from the parabolic root ideal \( \Delta(\eta) \) by removing trapezoids between consecutive blocks. For \( \ell \geq m = |\eta| \), we also define \( \Delta^\prime_\ell(\eta) \subset \Delta_\ell^{+} \) to be the root ideal \( \Delta^\prime(\eta) \cup \{(i, j) \in \Delta_\ell^{+} \mid j > |\eta|\} \).
Example 8.10. For $\eta = 732$, we have depicted $\Delta'(\eta)$ in red, $\Delta^+ \setminus \Delta(\eta)$ in light blue, and $\Delta(\eta) \setminus \Delta'(\eta)$ in blue (the two trapezoidal regions).

$$\Delta'(\eta) =$$

Theorem 8.11. Let $\alpha \in \mathbb{Z}_{\geq 0}^\ell$ and set $\eta = (\alpha^+)'$. Set $m = |\alpha|$ and put $\mu = 1^m 0^{\ell-m}$ if $m \leq \ell$ and $\mu = 1^m$ otherwise. The $t = 0$ nonsymmetric Macdonald polynomials agree with certain nonsymmetric Catalan functions:

$$\tilde{E}_\alpha(x_1, \ldots, x_\ell; q) = \begin{cases} H(\Delta'_t(\eta); \mu; \tilde{\rho}(\alpha))(x_1, \ldots, x_\ell; q) & \text{if } m \leq \ell \\ H(\Delta'(\eta); \mu; \tilde{\rho}(\alpha, 0^{m-\ell}))(x_1, \ldots, x_m; q) |_{x_{\ell+1} = \ldots = x_m = 0} & \text{if } m > \ell. \end{cases} \tag{8.13}$$

Proof. First assume $m \leq \ell$. The labeled root ideal $(\Delta'_t(\eta), \mu; \tilde{\rho}(\alpha))$ is tame because the $\ell - \eta_1$ 0’s in $\alpha^+$ ensure that $\eta_1 + 1, \ldots, \ell - 1$ is contained in the right descent set of $\tilde{\rho}(\alpha)$. Hence by (7.12) and then Proposition 8.2,

$$H(\Delta'_t(\eta); \mu; \tilde{\rho}(\alpha)) = q^{-n_\ell(|\mu|)} \text{char}(\text{AGD}(\mu; w)) = q^{-n_\ell(\mu)} \text{char}(B_w(\Lambda_0)),$$

where $w = (\tilde{\rho}(\alpha), s(\Delta'_t(\eta)))$, $w = \tilde{\rho}(\alpha) \tau s(n_1) \tau s(n_2) \cdots \tau s(n_{m-1}) \tau s(n_m) \in \tilde{H}_t$, $(n_1, \ldots, n_{\ell-1}) = s(\eta_1)$, and $n_m := 1$ (if $m < \ell$ this was already true otherwise we define it); the $s(n_m)$ here (allowed by Proposition 8.2) makes $w$ end in $\tau s(\eta_k) \tau s(\eta_k-1) \cdots \tau s(1)$, enabling the parts of $\eta$ to be handled uniformly below. Thus by Theorem 8.3, to prove the top case of (8.13) it suffices to show $B_w(\Lambda_0) = B_v(\Lambda_0)$, where $v = \tilde{\rho}(\alpha)(\tau s(\eta_k))^n_k(\tau s(\eta_{k-1}))^{n_{k-1}} \cdots (\tau s(\eta_1))^{n_1}$ as in Theorem 8.3 with $z = \tilde{\rho}(\alpha)$. Since $F_{w_0, \{u_\Lambda_0\}} = \{u_\Lambda_0\}$, it is enough to show $ww_0 = vw_0$ in the 0-Hecke monoid $\tilde{H}_t$.

For an interval $[i, j] \subset [m]$, set $w_{[i,j]} = \tau s(n_1) \tau s(n_2) \cdots \tau s(n_j)$, so that $w = \tilde{\rho}(\alpha)w_{[m]}$. By definition of $\Delta'_t(\eta)$, $w_{[m]} = (\tau s(\eta_1))^{n_1} \tau s(\eta_1-1) \tau s(\eta_2-2) \cdots \tau s(\eta_2+1)$. By Lemma 8.1 (i), for $j \in [m]$ and $n_j < i \leq \ell - 1$, $s_i w_{[j,m]} w_0 = w_{[j,m]} s_i w_0 = w_{[j,m]} w_0$. Hence

$$w_{[m]} w_0 = (\tau s(\eta_1))^{n_1+1} \tau s(\eta_1-1) \tau s(\eta_1-2) \cdots \tau s(\eta_2+1) w_{[m+1,m]} w_0 = \cdots = (\tau s(\eta_1))^{n_1} w_{[m+1,m]} w_0.$$

In Example 8.12, this amounts to removing the triangle as the first step in going from the left to middle diagram. Repeating this for the other parts of $\eta$ we obtain

$$ww_0 = \tilde{\rho}(\alpha)(\tau s(\eta_1))^n \cdots (\tau s(\eta_k))^n_k w_0 = \tilde{\rho}(\alpha)(\tau s(\eta_k))^n_k \cdots (\tau s(\eta_1))^n_1 w_0 = vw_0, \tag{8.14}$$

as desired. Here, we have used Lemma 8.1 (iv) for the second equality.

Now to handle the case $m > \ell$, we use the following stability property of the $t = 0$ nonsymmetric Macdonald polynomials which is straightforward to verify from the Haglund-Haiman-Loehr formula [24, Theorem 3.5.1]: for any $\beta \in \mathbb{Z}_{\geq 0}^\ell$, $E_{(\beta,0)}(x_1, \ldots, x_{\ell+1}; q, 0)|_{x_{\ell+1} = 0} = E_{(\beta,0)}(x_1, \ldots, x_\ell; q, 0)$. Thus we also have $\tilde{E}_{(\beta,0)}(x_1, \ldots, x_{\ell+1}; q)|_{x_{\ell+1} = 0} = \tilde{E}_{(\beta,0)}(x_1, \ldots, x_\ell; q)$. Applying this to $\tilde{E}_{(\alpha,0^{m-\ell})}(x_1, \ldots, x_m; q) = H(\Delta'(\eta); 1^m; \tilde{\rho}(\alpha, 0^{m-\ell}))(x_1, \ldots, x_m; q)$, which holds by the top case of (8.13), yields the bottom case of (8.13). \qed
Example 8.12. We assemble several expressions for $\tilde{E}_\alpha$ for $\alpha = 3221110000$ ($\ell = 10$). We have $\eta = (\alpha^+)^\vee = 631$ and $\Delta'(\eta)$ is indicated by the red squares in the left diagram below. Let $\mu = 1^\ell$ and note that $\tilde{p}(\alpha) = s_2 s_4 s_5 s_7 s_9 s_8 s_7 s_8$.

\[
\tilde{E}_\alpha = x_1 \Phi \pi_{s_1(1)}(x_1 \Phi \pi_{s_3(3)})^3(x_1 \Phi \pi_{s_6(6)})^6 \cdot 1
\]  
\[\text{(8.15)}\]

The last equality holds by Theorem 2.3. The left diagram below gives a way of visualizing (8.18)–(8.20) (in the style of Example 6.18), the middle diagram corresponds to (8.17), and the right diagram to (8.15)–(8.16).

8.3. Symmetrization to the Lascoux/Shimozono-Weyman formula.

Proof of Theorem 8.8. By Theorem 8.11 and Definition 2.1, $\pi_{w_0} \tilde{E}_\alpha = \pi_{w_0} H(\Delta'_\eta(\mu); \mu; \tilde{p}(\alpha)) = H(\Delta'_\eta(\mu; w_0); \mu; w_0)$. Hence the first equality of (8.11) will follow from

\[
H(\Delta'_\eta(\mu; w_0); \mu; w_0) = H(\Delta'_\eta(\mu; w_0)).
\]  
\[\text{(8.21)}\]

This identity can be seen by starting with $\Delta'_\eta(\mu)$ and filling in the trapezoidal regions of $\Delta'_\eta \setminus \Delta'_\eta(\mu)$ one root at a time, using [10, Lemma 8.9] to show that the corresponding Catalan functions remain the same (this is essentially the same argument used to prove [10, Lemma 10.1]). The second equality of (8.11) holds by Theorem 2.18.

Now to prove $\mathcal{F}_{w_0} B^{\mu; w} = B^{\mu; (w_0, s(\Delta'_\eta(\mu)))}$, we first apply Proposition 8.2 to obtain $\text{AGD}(\mu; (w_0, s(\Delta'_\eta(\mu)))) = B_{w_0}(\Lambda_0)$ and $\text{AGD}(\mu; (w_0, s(\Delta'_\eta(\mu)))) = B_y(\Lambda_0)$, where

\[
w := w_0 \tau s(\Delta'_\eta(\mu))_1 \cdots \tau s(\Delta'_\eta(\mu))_{m-1} \tau, \quad y := w_0 \tau s(\Delta'_\eta(\mu))_1 \tau s(\Delta'_\eta(\mu))_2 \cdots \tau s(\Delta'_\eta(\mu))_{m-1} \tau.
\]

Considering the given expressions for $w$ and $y$ as words in the $s_i$'s and $\tau$, we see the expression for $w$ is a subword of that of $y$, and hence $B_w(\Lambda_0) = \mathcal{F}_w \{ u_{\Lambda_0} \} \subset \mathcal{F}_y \{ u_{\Lambda_0} \} = B_y(\Lambda_0)$. But we also have $\text{char}_{x, \mu}(B_w(\Lambda_0)) = \text{char}_{x, \mu}(B_y(\Lambda_0))$ by Corollary 7.13 and (8.21). So equality $B_w(\Lambda_0) = B_y(\Lambda_0)$ holds.

Let $v$ and $w$ be as in Theorem 8.3 with $\mathbf{z} = \tilde{p}(\alpha)$. Then $w_0 v w_0 = w w_0$ by (8.14), and hence $\mathcal{F}_{w_0} B_e(\Lambda_0) = B_w(\Lambda_0) = B_y(\Lambda_0)$ (by Proposition 4.3). By Theorem 2.11, the equality of AGD crystals $\mathcal{F}_{w_0} B_e(\Lambda_0) = B_y(\Lambda_0)$ implies that the corresponding DARK crystals are equal (as subsets of $B^\mu$): $\mathcal{F}_{w_0} B^{\mu; w} = B^{\mu; (w_0, s(\Delta'_\eta(\mu)))}$. Equating the $U_q(\mathfrak{gl}_\ell)$-highest weights of these crystals then gives the first equality of (8.12) (with the help of Proposition 6.15); the connection to kattype follows from Proposition 7.7 and Theorem 8.7. \qed
The companion result to Theorem 8.8 for \( m > \ell \) is more technical and requires a crystal version of setting \( x_{\ell+1} = \cdots = x_m = 0 \), which we now describe.

Let \( B \) be a \( U_q(\mathfrak{gl}_m) \)-crystal which is a isomorphic to a disjoint union of highest weight crystals \( B^\nu(v) \) for \( v = (\nu_1 \geq \cdots \geq \nu_m \geq 0) \). The weight function takes values in \( \mathbb{Z}_{\geq 0}^m \) and we write \( \text{wt}(b) = (\text{wt}_1(b), \ldots, \text{wt}_m(b)) \) for the entries of \( \text{wt}(b) \). Let \( S \subseteq B \) be isomorphic to a disjoint union of \( U_q(\mathfrak{gl}_m) \)-Demazure crystals. Let \( \text{Res}_j B \) denote the \( U_q(\mathfrak{gl}_\ell) \)-restriction of \( B \) corresponding to Dynkin node subset \( J = [\ell-1] \subseteq [m-1] \) (see §4.2). By Theorem 4.1 \( \text{Res}_j S \) is isomorphic to a disjoint union of \( U_q(\mathfrak{gl}_\ell) \)-Demazure crystals. Define

\[
R^{\ell}_m S = \{ b \in S \mid \text{wt}_i(b) = 0 \text{ for all } i \in [\ell+1, m] \} \subseteq \text{Res}_j S.
\]  

(8.22)

Since \( \tilde{f}_j, j \in [\ell-1] \), fixes \( \text{wt}_i \) for \( i > \ell \), \( R^{\ell}_m S \) is also a disjoint union of \( U_q(\mathfrak{gl}_\ell) \)-Demazure crystals and its character is obtained from that of \( S \) by setting \( x_{\ell+1} = \cdots = x_m = 0 \).

Below we work with \( H_m \) and its submonoid \( H_\ell \) generated by \( s_1, \ldots, s_{\ell-1} \) (\( \ell \leq m \)); denote by \( \iota : H_\ell \hookrightarrow H_m \) the inclusion and \( w_{[1,m]} \) and \( w_{[1,\ell]} \) their longest elements.

**Lemma 8.13.** Let \( m \geq \ell \) and \( S \subseteq B \) as above. Then

\[
R^{\ell}_m \mathcal{F}_w S = \mathcal{F}_{w_{[1,\ell]}} R^{\ell}_m S.
\]  

(8.23)

**Proof.** Let \( s_{i_1} \cdots s_{i_k} \) be a reduced word for \( w_{[1,m]} \). For any \( b \in B \), \( \sum_{i=\ell+1}^m \text{wt}_i(\tilde{f}_i(b)) > \sum_{i=\ell+1}^m \text{wt}_i(b) \) and for \( j \neq \ell \), \( \sum_{i=\ell+1}^m \text{wt}_i(\tilde{f}_j(b)) = \sum_{i=\ell+1}^m \text{wt}_i(b) \); also, \( \sum_{i=\ell+1}^m \text{wt}_i(b) = 0 \) implies \( \tilde{f}_j(b) = 0 \) for \( j > \ell \). It follows that an arbitrary element \( \tilde{f}_{i_1}^{s_{i_1}} \cdots \tilde{f}_{i_k}^{s_{i_k}}(b) \) of \( \mathcal{F}_w S \) lies in \( R^{\ell}_m \mathcal{F}_w S \) if and only if \( b \in R^{\ell}_m S \) and \( a_{ij} = 0 \) whenever \( i_j > \ell \). Hence \( R^{\ell}_m \mathcal{F}_{w_{[1,m]}} S = \mathcal{F}_{w_{[1,\ell]}} R^{\ell}_m S \) where \( v \) is the product of the \( s_{ij} \) with \( i_j < \ell \). Since \( s_{i_1} \cdots s_{i_k} \) contains a reduced word for \( w_{[1,\ell]} \), it follows from Remark 4.4 that \( \mathcal{F}_{w_{[1,\ell]}} R^{\ell}_m S = \mathcal{F}_{w_{[1,\ell]}} R^{\ell}_m S \).

**Lemma 8.14.** Given \( n = (n_1, \ldots, n_{p-1}) \in [\ell]^{p-1} \) and \( z \in H_\ell \), define the tuples \( w = (z, s_{\ell-1} \cdots s_{n_1}, \ldots, s_{\ell-1} \cdots s_{n_{p-1}}) \in (H_\ell)^p \) and \( \bar{w} = (\ell(z), s_{m-1} \cdots s_{n_1}, \ldots, s_{m-1} \cdots s_{n_{p-1}}) \in (H_m)^p \). Then for any partition \( \mu = (\mu_1, \ldots, \mu_p) \), \( R^{\ell} B^{w; \bar{w}} = B^{\mu; w} \).

**Proof.** By Theorem 6.20, this is equivalent to showing that \( T \in \text{Tableoids}_\ell \) is \( w \)-katabolizable if and only if \( \overline{T} \) is \( \bar{w} \)-katabolizable, where \( \overline{T} \) is the same as \( T \) but regarded as an element of \( \text{Tableoids}_m \). One checks easily by induction that these two katabolism computations are essentially identical, the only difference being that whenever \( k \)-atatomb is applied in the \( w \)-katabolism algorithm, it matches the application of \( P_{s_{\ell-1} \cdots s_{n_1}} \circ \text{kat} \) in the \( \bar{w} \)-katabolism algorithm; this holds because at every step (in either algorithm) just before \( k \)-atatomb is applied, the input tableoid is empty in rows \( \ell+1, \ldots, m \).

**Theorem 8.15.** Maintain the notation of Theorem 8.3; also set \( m = p = |\alpha| \) and assume \( m > \ell \). Let \( SYT^{\ell}_{\alpha} = SSYT^{\ell}_{\alpha}(\mu) \), the SYT with \( m \) boxes and at most \( \ell \) rows. Then

\[
\pi^{\ell}_{w_{[1,\ell]}} F^{\alpha} = H(\Delta(\eta); \mu; w_{[1,m]})|_{x_{\ell+1}=\cdots=x_m=0} = \sum_{U \in SYT^{\ell}_{\alpha}} q^{\text{charge}(U)} s_{\text{shape}(U)}(x_1, \ldots, x_\ell).
\]  

(8.24)

Moreover, \( \mathcal{F}_{w_{[1,\ell]}} B^{w; \bar{w}} = R^{\ell}_m B^{w; (w_{[1,m]}, s(\Delta(\eta)))} \) as \( U_q(\mathfrak{gl}_\ell) \)-crystals, and so

\[
\{ P(T) \mid T \in \text{RowFrank}_{\ell}(\mu) \text{ is extreme \( w \)-katabolizable} \} =
\{ U \in SYT^{\ell}_{\alpha} \mid U \text{ is isomorphic to a disjoint union of } U_q(\mathfrak{gl}_\ell) \text{-Demazure crystals} \} = \{ U \in SYT^{\ell}_{\alpha} \mid \text{kattytype}(U) \geq \eta \}.
\]

(8.25)
Proof. By Theorem 8.8, applied with $m$ in place of $\ell$ and $(\alpha, 0^{m-\ell})$ in place of $\alpha$, $F_{w_{[1,m]}} B_{\mu,\tilde{\nu}}^{\mu,\tilde{\nu}} = B_{\mu,\pi(\Delta(m_n))}^{\mu,\tilde{\nu}}$ as $U_q(\mathfrak{gl}_m)$-crystals, where $\tilde{\nu} = (\nu(z), s_{m-1} \cdot \ldots \cdot s_{n_1}, \ldots, s_{m-1} \cdot \ldots \cdot s_{n_{m-1}}) \in (H_m)^n$ with $n = \eta_{1}^{n_1} \cdot \ldots \cdot \eta_{Z}^{n_{Z}} \cdot \eta_{1}^{-1}$. (Here $z$ is one of the inputs to Theorem 8.15, which can be any element of $\mathcal{H}_k$ satisfying $z^{\alpha_+} = \alpha$. In this application of Theorem 8.8 we must choose a $\tilde{z} \in \mathcal{H}_m$ such that $\tilde{z}(\alpha, 0^{m-\ell}) = (\alpha, 0^{m-\ell})$; we choose $\tilde{z} = \nu(z)$. Applying $R_{\ell}^m$ to both sides and then using Lemmas 8.13 and 8.14 yields the “moreover” statement:

$$R_{\ell}^m B_{\mu,\pi(\Delta(m_n))}^{\mu,\tilde{\nu}} = R_{\ell}^m F_{w_{[1,m]}} B_{\mu,\tilde{\nu}}^{\mu,\tilde{\nu}} = F_{w_{[1,\ell]}} R_{\ell}^m B_{\mu,\tilde{\nu}}^{\mu,\tilde{\nu}} = F_{w_{[1,\ell]}} B_{\mu,\tilde{\nu}}^{\mu,\tilde{\nu}},$$

and the consequence (8.25) follows much like the proof of (8.12). Next, it follows from Theorem 8.3 that the charge weighted character of $F_{w_{[1,\ell]}}$ is $\pi_{w_{[1,\ell]}} \tilde{E}_{\alpha}$ and that of $R_{\ell}^m F_{w_{[1,m]}} B_{\mu,\tilde{\nu}}^{\mu,\tilde{\nu}}$ is $(\pi_{w_{[1,m]}} \tilde{E}_{\alpha, 0^{m-\ell}})|_{x_{m+1} = \ldots = x_{m} = 0} = \pi_{w_{[1,\ell]}} \tilde{E}_{\alpha}$. This fact given, (8.24) is obtained by applying Theorem 8.8 (specifically (8.11)), with $(\alpha, 0^{m-\ell})$ in place of $\alpha$ and then setting $x_{\ell+1} = \ldots = x_{m} = 0$. 

Acknowledgments. We are grateful to Peter Littelmann and Wilberd van der Kallen for the proof of Theorem 4.1. We thank Mark Haiman, George Seelinger, Mark Shimozono, and Weiqiang Wang for helpful discussions and Elaine So for help typing and typesetting figures.

Figure 5. The tensor product of KR crystals $B^\mu = B^{1,1} \otimes B^{1,1} \otimes B^{1,1}$, which is also the DARK crystal $B^{\mu|w}$ for $\mu = (1,1,1)$ and $w = (s_2s_1,s_2s_1,s_2s_1)$. Its charge weighted character is the modified Hall-Littlewood polynomial $H_{111}(x; q) = s_{111} + (q + q^2)s_{21} + q^3s_{31} = \kappa_{111} + (q + q^2)\kappa_{012} + q^3\kappa_{003}$. Horizontal and vertical arrows give the $\tilde{f}_1, \tilde{f}_2$ edges, respectively. The dashed arrows are the $\tilde{f}_0$-edges of $B^\mu \otimes B(\Lambda_0)$ which have both ends in $B^{\mu|w} \otimes u_{\Lambda_0} \subset B^\mu \otimes B(\Lambda_0)$. Since $\mu$ is constant, the corresponding generalized Demazure crystal $\text{AGD}(\mu; w) = \Theta_\mu(B^{\mu|w} \otimes u_{\Lambda_0})$ (via Theorem 2.11) is an actual affine Demazure crystal, namely $\mathcal{F}_{s_2s_1\tau s_2s_1\tau s_2s_1}\{u_{\Lambda_1}\} \subset B(\Lambda_0)$.

Shown bold is the DARK crystal $B^{\mu|v} = (\mathcal{F}_{\tau}\mathcal{F}_{s_2s_1}(\mathcal{F}_{\tau}\mathcal{F}_{s_2s_1}(b_1) \otimes b_1)) \otimes b_1$, for $\mu = (1,1,1)$, $v = (id, s_2s_1, s_2s_1)$, which has charge weighted character $\kappa_{111} + q\kappa_{102} + q^2\kappa_{201} + q^3\kappa_{300}$, also equal to the $t = 0$ nonsymmetric Macdonald polynomial $\tilde{E}_{300}(x; q)$ and the nonsymmetric Catalan function $H(\Delta^+; \mu; s_2)$. Again, the corresponding generalized Demazure crystal $\text{AGD}(\mu; v) = \Theta_\mu(B^{\mu|v} \otimes u_{\Lambda_0}) = \mathcal{F}_{\tau s_2s_1\tau s_2s_1\tau s_2s_1}\{u_{\Lambda_1}\} \subset B(\Lambda_0)$ is an affine Demazure crystal.
