SELF-SIMILAR SOLUTIONS OF KINETIC-TYPE EQUATIONS:
THE CRITICAL CASE

KAMIL BOGUS, DARIUSZ BURACZEWSKI AND ALEXANDER MARYNYCH

Abstract. For a time dependent family of probability measures \((\rho_t)_{t \geq 0}\) we consider a kinetic-type evolution equation \(\partial \phi_t/\partial t + \phi_t = \hat{Q}\phi_t\), where \(\hat{Q}\) is a smoothing transform and \(\phi_t\) is the Fourier–Stieltjes transform of \(\rho_t\). Assuming that the initial measure \(\rho_0\) belongs to the domain of attraction of a stable law, we describe asymptotic properties of \(\rho_t\), as \(t \to \infty\). We consider the critical regime when the standard normalization leads to a degenerate limit and find an appropriate scaling ensuring a non-degenerate self-similar limit. Our approach is based on a probabilistic representation of probability measures \((\rho_t)_{t \geq 0}\) that refines the corresponding construction proposed in Bassetti and Ladelli [Ann. Appl. Probab. 22(5): 1928–1961, 2012].

1. Introduction

In the paper we consider a kinetic-type evolution equation for a time dependent family of probability measures \((\rho_t)_{t \geq 0}\). Let

\[ \phi(t, \xi) = \int_{\mathbb{R}} e^{i \xi v} \rho_t(dv), \quad t \geq 0, \quad \xi \in \mathbb{R}, \]

be the Fourier–Stieltjes transform (the characteristic function) of \(\rho_t\). We are interested in the solution of the following Cauchy problem

\[ \frac{\partial}{\partial t} \phi(t, \xi) + \phi(t, \xi) = \hat{Q}(\phi(t, \cdot), \ldots, \phi(t, \cdot))(\xi), \quad t > 0, \quad \phi(0, \xi) = \phi_0(\xi), \quad \xi \in \mathbb{R}, \]

where \(\hat{Q}\) is a smoothing transform. The smoothing transform \(\hat{Q}\) is defined by the equality

\[ \hat{Q}(\phi_1, \ldots, \phi_N)(\xi) := \mathbb{E}(\phi_1(A_1 \xi) \cdots \phi_N(A_N \xi)), \quad \xi \in \mathbb{R}, \]

where \(\phi_1, \ldots, \phi_N\) are characteristic functions, \(N\) is a fixed positive integer, and a random vector \(A = (A_1, \ldots, A_N)\) consists of positive real-valued random variables defined on a common probability space \((\Omega, \mathcal{F}, \mathbb{P})\). The initial condition \(\phi_0\) is the characteristic function of some random variable \(X_0\) defined on \((\Omega, \mathcal{F}, \mathbb{P})\).

The equation of the form (1.1) with \(N = 2\) and \(A = (\sin \theta, \cos \theta)\), where \(\theta\) is a random angle uniformly distributed on \([0, 2\pi]\), was introduced and investigated by Kac [10] as a model of behavior of a particle in a homogeneous gas. In subsequent works the Kac...
Further, we define the function $\hat{g}$ where there exists a parameter $\mu$, depending on the initial condition $\phi_0$ and the law of $A$, such that the rescaled solution to (1.1), namely
\[(1.2) \quad w(t,\xi) = \phi(t, e^{-\mu t} \xi), \quad t \geq 0, \quad \xi \in \mathbb{R},\]
converges to a nondegenerate limit as $t \to \infty$ and the limit is a self-similar solution to a smoothing transform pertained to $\hat{Q}$. The main goal of our paper is to present a class of solutions to (1.1) which, after rescaling as in (1.2), converge to a degenerate limit, yet it is possible to find a different normalization ensuring a nondegenerate limit possessing some self-similarity properties. To achieve our aims we propose a refinement of the probabilistic construction of the solution $\phi$ presented in [5] and express $\phi$ via a continuous-time branching random walk.

Firstly, we state assumptions concerning the initial condition $\phi_0$. We suppose, similarly as in [4], that the distribution function $F_0$ of $X_0$ satisfies one of the following hypotheses ($H_\gamma$) for some $\gamma \in (0,2]$:

$(H_1)$ either
\[(a) \int_\mathbb{R} |v| \, dF_0(v) < +\infty \text{ and then we set } m_0 := \int_\mathbb{R} v \, dF_0(v)\]
or
\[(b) F_0 \text{ is a symmetric distribution function that satisfies the condition } \lim_{x \to +\infty} x(1 - F_0(x)) = \lim_{x \to -\infty} |x| F_0(x) = c_0^+ \in (0,\infty).\]

$(H_2)$ $0 < \sigma_0^2 := \int_\mathbb{R} |v|^2 \, dF_0(v) < +\infty \text{ and } \int_\mathbb{R} v \, dF_0(v) = 0.$

$(H_\gamma)$ If $\gamma \in (0,1) \cup (1,2)$, $F_0$ satisfies the conditions
\[\lim_{x \to +\infty} x^\gamma (1 - F_0(x)) = c_0^+ < +\infty, \quad \lim_{x \to -\infty} |x|^\gamma F_0(x) = c_0^- < +\infty\]
with $c_0^+ + c_0^- > 0$ and, in addition, $\int_\mathbb{R} v \, dF_0(v) = 0$ if $\gamma \in (1,2)$.

Further, we define the function $\hat{g}_\gamma : \mathbb{R} \mapsto \mathbb{C}$ by
\[(1.3) \quad \hat{g}_\gamma(\xi) := \begin{cases} 
 e^{im_0 \xi}, & \text{if } \gamma = 1 \text{ and (a) of } (H_1) \text{ holds,} \\
 e^{-\pi c_0^+ |\xi|}, & \text{if } \gamma = 1 \text{ and (b) of } (H_1) \text{ holds,} \\
 e^{-\sigma_0^2 |\xi|^2 / 2}, & \text{if } \gamma = 2 \text{ and } (H_2) \text{ holds,} \\
 e^{-k_0 |\xi|^{\gamma(1-\eta_0) \tan(\pi/2) \sin(\pi/2)}} & \text{if } \gamma \in (0,1) \cup (1,2) \text{ and } (H_\gamma) \text{ holds,}
\end{cases}\]

where
\[k_0 = (c_0^+ + c_0^-) \frac{\pi}{2\Gamma(\gamma) \sin(\pi/2)}, \quad \eta_0 = \frac{c_0^+ - c_0^-}{c_0^+ + c_0^-}.\]

Observe, that except the case (a) of $(H_1)$, the condition $(H_\gamma)$ is equivalent to the fact that the law of $X_0$ is centered for $\gamma \geq 1$ in the sense that $\mathbb{E}X_0 = 0$ for $\gamma > 1$ and $X_0 \overset{d}{=} -X_0$. We refer to [4, 5] for other examples and a comprehensive bibliography.
for $\gamma = 1$, and belongs to the domain of normal attraction of a $\gamma$-stable law with the characteristic function $\hat{g}_\gamma$.

Now we formulate our hypotheses on the smoothing transform $\hat{Q}$. Our first assumption is that the weights $(A_i)_{i=1,\ldots,N}$ are a.s. nonnegative. Next we define the function $\Phi : [0, \infty) \mapsto \mathbb{R} \cup \{+\infty\}$ via
\[
\Phi(s) = \mathbb{E} \left[ \sum_{i=1}^{N} A_i^s \right] - 1, \quad s \geq 0,
\]
and assume that $s_\infty > 0$ where $s_\infty := \sup\{s \geq 0 : \Phi(s) < \infty\}$. Note that the function $\Phi$ is smooth and convex on $(0, s_\infty)$. The function $\mu(s) = \Phi(s)/s$, $s > 0$, is called spectral function, see [7]. Observe that $\mu(s)$ is equal to the tangent of the angle between the vector joining $(0, 0)$ and $(s, \Phi(s))$ and the positive horizontal half-axis. Since $\Phi$ is convex and smooth there exists exactly one point $\gamma^*$ minimizing the spectral function, and then the corresponding line is just tangent to the function $\Phi$ at point $(\gamma^*, \Phi(\gamma^*))$. Moreover, $\mu(\gamma^*) = \Phi'(\gamma^*)$.

In the series of papers [4, 5] Basetti, Ladelli and Matthes found a probabilistic interpretation of the solution $\phi$ via labelled random trees. Assuming that $(H_\gamma)$ holds for some $\gamma \in (0, 2]$ and there exists $\delta > \gamma$ such that $\mu(\delta) < \mu(\gamma) < \infty$, it is shown in [4, Theorem 2.2] that $\phi(t, e^{-\mu(\gamma)t}\xi)\Rightarrow w_\infty(\xi)$, $\xi \in \mathbb{R}$, and $w_\infty$ has the following representation $w_\infty(\xi) = \mathbb{E}\hat{g}_\gamma(\xi c_\gamma D_\infty^{1/\gamma})$, where $c_\gamma := \left(2 \pi^{-\gamma} \Phi'(\gamma) \right)^{\frac{1}{\gamma}}$ and $D_\infty$ is a.s. positive random variable which satisfies the following stochastic fixed-point equation
\[
D_\infty \overset{d}{=} U^{\Phi(\gamma)} \sum_{k=1}^{N} A_k^\gamma D_\infty^{(k)},
\]
where \((D_\infty^{(k)})_{k=1}^{N}\) are independent copies of \(D_\infty\); \(U\) has a uniform distribution on \((0,1)\) and
\((D_\infty^{(k)})_{k=1}^{N}, U\) and \((A_1,\ldots,A_N)\) are independent.

The rest of the paper is organized as follows. In Section 2 we describe a probabilistic representation of the solution \(\phi\), which is essentially very similar to the construction in \cite{4} but is more transparent and convenient for the analysis. Moreover, we reveal some further probabilistic structure behind this construction by pointing out a connection to Yule processes and branching random walks in continuous time. We strongly believe that the representation proposed in Section 2 is the most accurate probabilistic interpretation of the solution to equation (1.1). In Section 3 we prove a convergence result for the Biggins martingale in continuous time branching random walk and explain the construction of the limiting measure \(\rho_\infty\). The proof of Theorem 1.4 is given in Section 4.

2. Probabilistic representation of the solution

The solution to the equation (1.1) can be derived analytically in terms of the the Wild series \cite{17}, see also Kielek \cite{11}. However, based on McKean’s \cite{14} ideas, Bassetti, Ladelli and Matthes \cite{4, 5} expressed the solution in a convenient probabilistic way.

The probabilistic construction of the solution \(\phi\) using labelled \(N\)-ary random trees is given on pp. 1938–1939 of \cite{4}, see Proposition 3.2 therein. However, the construction proposed in \cite{4} is not fully rigorous because only one-dimensional distributions of \((\nu_t)_{t\geq0}\) are specified and the process \((\nu_t)_{t\geq0}\) used therein is not completely defined, see formula (3.4) in \cite{4}. Moreover, nothing is mentioned about probabilistic interpretation of the process \((\nu_t)_{t\geq0}\). The main purpose of this subsection is to show how to construct the process \((\nu_t)_{t\geq0}\) and provide an alternative form of Proposition 3.2 of \cite{4} revealing the complete probabilistic interpretation of the solution \(\phi\). As we will see, \(\phi(t,\cdot)\) is nothing else but the characteristic function of a smoothing transform associated with a certain continuous-time branching random walk and applied to the distribution of \(X_0\), see Proposition 2.5 below.

2.1. Representation of the solutions and connection with branching random walks in continuous time. Let us recall that a Yule process \((Y_t)_{t\geq0}\) is a pure birth process which starts with one particle. After exponential time with parameter 1 the original particle dies out and produces \(N\) new particles. Every particle behaves as the original one, and the particles reproduce independently. The quantity \(Y_t\) is the number of particles at time \(t\geq0\). Denote by \(F(s,t)\) the probability generating function of \(Y_t\), that is

\[
F(s,t) = \mathbb{E}s^{Y_t}, \quad t \geq 0, \quad |s| \leq 1.
\]

Using equations (5) and (6) on p. 106 in \cite{3}, see also example on p. 109 in the same reference, we obtain

\[
\frac{\partial F(s,t)}{\partial t} = F^N(s,t) - F(s,t), \quad t > 0, \quad F(s,0) = s.
\]

By solving this differential equation, we get the explicit solution

\[
F(s,t) = s \left( \frac{e^{-(N-1)t}}{1 - s^{N-1}(1 - e^{-(N-1)t})} \right)^{\frac{1}{N-1}}, \quad t \geq 0, \quad |s| \leq 1.
\]
The full genealogical tree $T_\infty$ of the Yule process $(Y_t)_{t \geq 0}$ is an infinite $N$-ary random tree. For every fixed $T \geq 0$ the genealogical tree of $(Y_t)_{t \in [0,T]}$ is a finite $N$-ary random tree with leaves representing the particles alive at time $T$ and internal nodes being the particles which have died out during $[0,T]$. Denote the latter quantity by $\nu_T$. We have the following identity
\begin{equation}
Y_t = (N-1)\nu_t + 1, \quad t \geq 0.
\end{equation}
From this representation and formula (2.1) we get
\begin{equation}
E s^{\nu_t} = e^{-t} \left( 1 - s \left( 1 - e^{-(N-1)t} \right) \right)^{-\frac{1}{N-1}}
= \sum_{k \geq 0} \frac{\Gamma \left( \frac{1}{N-1} + k \right)}{k! \Gamma \left( \frac{1}{N-1} \right)} e^{-t} (1 - e^{-(N-1)t})^k s^k, \quad t \geq 0, \quad |s| \leq 1,
\end{equation}
in full agreement with formula (3.4) in [4]. That is to say, the process $(\nu_t)_{t \geq 0}$ introduced in [4], should be interpreted as the number of splits during the time interval $[0,t]$ in the Yule process $(Y_t)_{t \geq 0}$. This interpretation of the distribution of $\nu_t$ is the starting point of our probabilistic construction of the solution $\phi$.

By adding to the definition of a Yule process the control over positions of particles, we obtain a continuous-time branching random walk. More precisely, let $\zeta = \sum_{N} k \delta_{Z_k}$ be an arbitrary point process on $\mathbb{R}$, where the number $N$ of atoms can be random and is assumed a.s. finite, and $\delta_x$ denotes the Dirac point measure at $x \in \mathbb{R}$. In the continuous-time branching random walk the initial single particle is located at 0. After an exponential time with parameter 1 it dies out and gives birth to $N$ new particles which are placed at positions $(Z_1, \ldots, Z_N)$. These particles reproduce independently in the same fashion as their mother. In particular, if at any time a particle located at some $x \in \mathbb{R}$ splits, its children are placed at $x + Z_1, \ldots, x + Z_N$. In what follows we only consider branching random walks with deterministic number of children of every particle. Clearly, the number of particles in such a continuous-time branching random walk at time $t \geq 0$ is just $Y_t$. Denote the locations of particles present at time $t$ by $z_{1,t}, z_{2,t}, \ldots, z_{Y_t,t}$. The continuous-time branching random walk is formally defined as the measure-valued stochastic process
\begin{equation}
Z_t := \sum_{k=1}^{Y_t} \delta_{z_{k,t}}, \quad t \geq 0.
\end{equation}
It will be important that the process $(Z_t)_{t \geq 0}$ satisfies the following branching relation:
\begin{equation}
Z_{t+s}(\cdot) \overset{d}{=} \sum_{k=1}^{Y_t} Z_s^{(k)}(\cdot - z_{k,t}), \quad t, s \geq 0,
\end{equation}
where $(Z_t^{(k)})_{t \geq 0}$ for $k \in \mathbb{N}$ are independent copies of $(Z_t)_{t \geq 0}$.

Finally, given a continuous-time branching random walk $(Z_t)_{t \geq 0}$, the associated family of smoothing transforms $(L_t)_{t \geq 0}$ on the space of probability distributions on $\mathbb{R}$ is defined by
\begin{equation}
L_t(\text{distr}(U)) = \text{distr} \left( \sum_{k=1}^{Y_t} e^{\gamma z_{k,t}} U_k \right),
\end{equation}
where \((U_k)_{k \geq 1}\) are independent copies of a random variable \(U\) and \(\gamma \in \mathbb{C}\) is a parameter. By slightly abusing notation we write \(L_t(U)\) instead of \(L_t(\text{distr}(U))\).

We are ready to state the main result of this subsection, namely the probabilistic representation of the solution \(\phi\) to kinetic-type equation (1.1). Assume that on the probability space \((\Omega, \mathcal{F}, P)\) the following two objects are defined:

- the continuous time branching random walk \((Z_t)_{t \geq 0}\) with the displacement process \(\zeta := \sum_{k=1}^{N} \delta \log A_k:\)
  \[ Z_t := \sum_{k=1}^{Y_t} \delta_{z_{k,t}}, \quad t \geq 0. \]

- the sequence \((X_k)_{k \geq 1}\) of independent random variables with common distribution function \(F_0\), which is also independent of \((Z_t)_{t \geq 0}\).

**Proposition 2.5.** Equation (1.1) has a unique solution \(\phi(t, \cdot)\) which is given by

\[ \phi(t, \xi) = \mathbb{E} \exp \left( i \xi \left( \sum_{k=1}^{Y_t} e^{x_k} X_k \right) \right), \quad t \geq 0, \quad \xi \in \mathbb{R}, \]

that is \(\phi(t, \cdot)\) is the characteristic function of the random variable \(L_t(X_0)\), where \(L_t\) is the smoothing transform associated with the continuous-time branching random walk \((Z_t)_{t \geq 0}\).

**Proof.** It is enough to show that the right-hand side of (2.6) satisfies (1.1). To this end, denote the the right-hand side of (2.6) by \(\psi(t, \xi)\) and write

\[ \psi(t, \xi) = \mathbb{E} \left[ \prod_{k=1}^{Y_t} \phi_0(\xi e^{z_{k,t}}) \right] = \mathbb{E} \exp \left( \int_{\mathbb{R}} \log \phi_0(\xi e^y) Z_t(dy) \right), \quad t \geq 0, \quad \xi \in \mathbb{R}. \]

Firstly, let us show that \(t \mapsto \psi(t, \xi)\) is continuous for every fixed \(\xi\). For \(t, s \geq 0\) we can write

\[ |\psi(t, \xi) - \psi(s, \xi)| \leq 2\mathbb{P}\{\text{there are splits during } [t \wedge s, t \vee s]\} = 2\mathbb{E}(1 - e^{-Y_{t \wedge s}[t-s]}) \to 0, \]

as \(s \to t\), by the dominated convergence theorem and the observation \(Y_t < \infty\) a.s.

Further, for \(t \geq 0\), let \(\mathcal{F}_t \subset \mathcal{F}\) be the \(\sigma\)-algebra generated by \((Z_s)_{s \in [0,t]}\). For \(h \geq 0\), using formula (2.4), we obtain

\[ \psi(t + h, \xi) = \mathbb{E} \left( \mathbb{E} \left( \exp \left( \int_{\mathbb{R}} \log \phi_0(\xi e^y) Z_{t+h}(dy) \right) \mid \mathcal{F}_h \right) \right) \]
\[ = \mathbb{E} \left( \mathbb{E} \left( \left. \prod_{k=1}^{Y_h} \exp \left( \int_{\mathbb{R}} \log \phi_0(\xi e^{y} e^{z_{k,h}}) Z_{t}^{(k)}(dy) \right) \right) \mid \mathcal{F}_h \right) \right) \]
\[ = \mathbb{E} \left( \left. \prod_{k=1}^{Y_h} \mathbb{E} \left( \exp \left( \int_{\mathbb{R}} \log \phi_0(\xi e^y e^{z_{k,h}}) Z_{t}^{(k)}(dy) \right) \right) \right) \mid \mathcal{F}_h \right) \]
\[ = \mathbb{E} \left( \left. \prod_{k=1}^{Y_h} \psi(t, \xi e^{z_{k,h}}) \right) \right). \]
The probability of having two or more splits in the branching random walk \((Z_t)_{t \geq 0}\) during \([0, h]\) is \(o(h)\) as \(h \to +0\), whence

\[
\psi(t + h, \xi) = \mathbb{E}\left( \prod_{k=1}^{\gamma_h(t)} \psi(t, \xi e^{z_k h}) \right) = \psi(t, \xi) \mathbb{P}\{\text{there are no splits during } [0, h]\} + \mathbb{E}\left( \prod_{j=1}^{N} \psi(t, \xi A_j) \right) \mathbb{P}\{\text{there is exactly one split during } [0, h]\} + o(h)
\]

Likewise, we can write for \(h \geq 0\) and \(t \geq h\):

\[
\psi(t, \xi) = \mathbb{E}\left( \prod_{k=1}^{\gamma_h(t-h)} \psi(t-h, \xi e^{z_k h}) \right) = \psi(t-h, \xi) \mathbb{P}\{\text{there are no splits during } [0, h]\}
\]

Rearranging the terms and sending \(h \to +0\) shows that

\[
\frac{\partial \psi(t, \xi)}{\partial t} + \psi(t, \xi) = \mathbb{E}\left( \prod_{j=1}^{N} \psi(t, \xi A_j) \right) = \hat{Q}(\psi(t, \cdot), \ldots, \psi(t, \cdot)), \quad t > 0,
\]

by the dominated convergence theorem and continuity of \(t \mapsto \psi(t, \xi)\) (this is required for the left derivative). Therefore, \(\psi\) is a solution to \([1.1]\). Since the solution is unique and \(\psi(0, \xi) = \phi_0(\xi) = \phi(0, \xi)\), we infer \(\psi(t, \xi) \equiv \phi(t, \xi)\). The proof is complete.

3. Convergence of the continuous-time Biggins martingale in the critical case.

For every \(\gamma \in [0, s_{\infty})\), put

\[
\mathcal{M}_t(\gamma) := e^{-\Phi(\gamma) t} \sum_{k=1}^{\gamma_t} e^{\gamma z_k t}, \quad t \geq 0,
\]

and note that by formula (5.1) in [6] we have

\[
(3.1) \quad \mathbb{E}\mathcal{M}_t(\gamma) = 1.
\]
The stochastic process \((M_t(\gamma))_{t \geq 0}\) is a martingale and is called continuous-time Biggins martingale.

If \(\gamma = \gamma^* = \arg\min_{s \in [0, s_\infty]} \mu(s)\), then the Biggins martingale \((M_t(\gamma^*))_{t \geq 0}\) converges to zero a.s. Our aim here is to prove the following proposition. The first part of this result has been stated without a proof in Remark 2.11(iii) of the recent paper [8].

**Proposition 3.2.** Assume that \(\gamma^* \in (0, s_\infty)\). The following limit relations hold true.

(i) As \(t \to \infty\) we have

\[
\sqrt{t}M_t(\gamma^*) = \sqrt{t} \sum_{k=1}^{Y_t} e^{\gamma^* z_{k,t}} \xrightarrow{p} \sqrt{\frac{2}{\pi(\gamma^*)^2\Phi''(\gamma^*)}} D_\infty,
\]

where \(z_{k,t}^0 = z_{k,t} - t\mu(\gamma^*)\), \(D_\infty\) is the a.s. limit of the derivative martingale

\[
D_t(\gamma^*) := \sum_{k=1}^{Y_t} e^{\gamma^* z_{k,t}^0} z_{k,t}^0, \quad t \geq 0,
\]

and \(D_\infty\) is a.s. positive.

(ii) Moreover,

\[
\sqrt{t} \max_{k=1, \ldots, Y_t} e^{\gamma^* z_{k,t}} \xrightarrow{p} 0, \quad t \to \infty.
\]

The proof of this result relies on two auxiliary lemmas which show that the Biggins martingale \((M_t(\gamma^*))_{t \geq 0}\) is in the so-called boundary case. In particular, this implies that every \(\theta\)-skeleton, that is the discrete-time Biggins martingale \((M_{n\theta}(\gamma^*))_{n \geq 0}, \theta > 0,\) is also in the boundary case. Thereafter, we apply the corresponding theorem by Aidékon and Shi [2], who found the appropriate normalization for the discrete-time Biggins martingales in the boundary case, to our \(\theta\)-skeletons and then pass to the continuous parameter with the aid of the Croft–Kingman lemma.

**Lemma 3.6.** Assume that \(\gamma^* \in (0, s_\infty)\). For every \(t \geq 0\) we have

\[
E\left[\sum_{k=1}^{Y_t} e^{\gamma^* z_{k,t}^0} z_{k,t}^0\right] = 0 \quad \text{and} \quad E\left[\sum_{k=1}^{Y_t} e^{\gamma^* z_{k,t}^0} (z_{k,t}^0)^2\right] = t(\gamma^*)^2\Phi''(\gamma^*).
\]

**Proof.** Fix \(\varepsilon \in (0, \gamma^*)\) such that \(\gamma^* + \varepsilon < s_\infty\). Let us show that for every fixed \(t \geq 0\) the following holds:

\[
E\left[\sum_{k=1}^{Y_t} e^{\gamma^* z_{k,t}^0} z_{k,t}^0\right] = \frac{\partial}{\partial \gamma} \left[ E\left[ e^{\gamma y} Z_t(dy) \right] \right]_{\gamma = \gamma^*}.
\]

To this end, it is enough to check that the partial derivative on the right-hand side can be moved inside the expectation and the integration signs. But this is a simple consequence of the dominated convergence theorem, since

\[
\lim_{\Delta \to 0} \int_{\Omega} \int_{\mathbb{R}} \frac{e^{(\gamma^* + \Delta)y} - e^{\gamma^* y}}{\Delta} Z_t(dy) d\mathbb{P} = \lim_{\Delta \to 0} \int_{\Omega} \int_{\mathbb{R}} \frac{e^{\Delta y} - 1}{\Delta} e^{\gamma^* y} Z_t(dy) d\mathbb{P},
\]

and the absolute value of the integrand is bounded by the integrable function

\[
y \mapsto e^{(\gamma^* + \varepsilon)y} 1_{\{y \geq 0\}} + e^{(\gamma^* - \varepsilon)y} 1_{\{y < 0\}}.
\]
for sufficiently small $\Delta$ and all $y \in \mathbb{R}$.

Using formula (3.1) we derive

$$
\mathbb{E} \left[ \sum_{k=1}^{\mathcal{N}} e^{\gamma^* z_{k,t}} z_{k,t} \right] = \frac{\partial}{\partial \gamma} \left( e^{t\Phi(\gamma)} \right) \bigg|_{\gamma = \gamma^*} = t\Phi'(\gamma^*) e^{t\Phi(\gamma^*)}, \quad t \geq 0.
$$

This immediately yields

$$
\mathbb{E} \left[ \sum_{k=1}^{\mathcal{N}} e^{\gamma^* z_{k,t}} z_{k,t}^2 \right] = e^{-t\Phi(\gamma^*)} \left( t\Phi'(\gamma^*) e^{t\Phi(\gamma^*)} \right) - t\mu(\gamma^*) \mathbb{E} \mathcal{M}_t(\gamma^*) = t \left( \Phi'(\gamma^*) - \mu(\gamma^*) \right) = 0.
$$

The second claim in (3.7) follows from the formula

$$
\mathbb{E} \left[ \sum_{k=1}^{\mathcal{N}} e^{\gamma^* z_{k,t}} z_{k,t}^2 \right] = \frac{\partial^2}{\partial \gamma^2} \left( \mathbb{E} \int_{\mathbb{R}} e^{\gamma y} z_t(dy) \right) \bigg|_{\gamma = \gamma^*},
$$

which can be proved similarly. The proof is complete.

\[\square\]

**Lemma 3.8.** Assume that $\gamma^* < s_\infty$. Then for every fixed $t \geq 0$ and $\delta > 0$ such that $(1 + \delta)\gamma^* < s_\infty$ we have

$$
\mathbb{E} \left[ \left( \sum_{k=1}^{\mathcal{N}} e^{\gamma^* z_{k,t}} \right)^{1+\delta} \right] < \infty \quad \text{and} \quad \mathbb{E} \left[ \left( \sum_{k=1}^{\mathcal{N}} e^{\gamma^* z_{k,t}(z_{k,t}^*)} \right)^{1+\delta} \right] < \infty,
$$

where $x_+ := \max(x, 0)$.

**Proof.** Let us prove the first claim. Using the inequality

$$
\left( \sum_{k=1}^{n} x_k \right)^{1+\delta} \leq \left( \sum_{k=1}^{n} x_k^{1+\delta} \right)^{1+\delta} \leq n^\delta \left( \sum_{k=1}^{n} x_k \right)^{1+\delta}
$$

which holds for $n \in \mathbb{N}$ and arbitrary nonnegative reals $x_1, x_2, \ldots, x_n$, we infer

$$
\mathbb{E} \left( \sum_{k=1}^{\mathcal{N}} e^{\gamma^* z_{k,t}} \right)^{1+\delta} \leq \mathbb{E} \left( \sum_{k=1}^{\mathcal{N}} e^{(1+\delta)\gamma^* z_{k,t}} \right)^{1+\delta} = \sum_{k=1}^{\mathcal{N}} \mathbb{E} \left( \gamma_t^\delta e^{(1+\delta)\gamma^* z_{k,t}} 1_{\{k \leq \mathcal{Y}_t\}} \right).
$$

Pick $p > 1$ such that $p(1 + \delta)\gamma^* < s_\infty$ and $q > 1$ such that $1/p + 1/q = 1$. By Hölder’s inequality we obtain

$$
\mathbb{E} \left( \gamma_t^\delta e^{(1+\delta)\gamma^* z_{k,t}} 1_{\{k \leq \mathcal{Y}_t\}} \right) \leq \left( \mathbb{E} e^{p(1+\delta)\gamma^* z_{k,t}} 1_{\{k \leq \mathcal{Y}_t\}} \right)^{1/p} \left( \mathbb{E} \gamma_t^q 1_{\{k \leq \mathcal{Y}_t\}} \right)^{1/q},
$$

and thereupon

$$
(3.9) \quad \mathbb{E} \left( \sum_{k=1}^{\mathcal{N}} e^{\gamma^* z_{k,t}} \right)^{1+\delta} \leq \sum_{k=1}^{\infty} \left( \mathbb{E} e^{p(1+\delta)\gamma^* z_{k,t}} 1_{\{k \leq \mathcal{Y}_t\}} \right)^{1/p} \left( \mathbb{E} \gamma_t^q 1_{\{k \leq \mathcal{Y}_t\}} \right)^{1/q}
$$

$$
\leq \left( \sum_{k=1}^{\infty} \mathbb{E} e^{p(1+\delta)\gamma^* z_{k,t}} 1_{\{k \leq \mathcal{Y}_t\}} \right)^{1/p} \left( \sum_{k=1}^{\infty} \mathbb{E} \gamma_t^q 1_{\{k \leq \mathcal{Y}_t\}} \right)^{1/q},
$$
where the last passage is a consequence of Hölder’s inequality for series. The first factor on the right-hand side is finite because $p(1 + \delta) \gamma^* < s_\infty$ and
\[
\sum_{k=1}^\infty \mathbb{E} e^{\sum_{k=1}^\infty p(1 + \delta) \gamma^* z_{k,t}} 1_{\{k \leq Y_t\}} = \mathbb{E} \left( \sum_{k=1}^\infty e^{p(1 + \delta) \gamma^* z_{k,t}} \right) = \mathbb{E} \int e^{p(1 + \delta) \gamma^* y} Z_t(dy) = e^{\Phi(p(1 + \delta) \gamma^*)t} < \infty.
\]
Formulæ (2.2) and (2.3) imply that $Y_t$ has exponential moment of some positive order for every fixed $t$. Therefore,
\[
\sum_{k=1}^\infty \mathbb{E} Y_t^{q\delta} 1_{\{k \leq Y_t\}} = \mathbb{E} Y_t^{q\delta + 1} < \infty
\]
and the proof of the first claim is complete.

To prove the second inequality we use exactly the same arguments to get the upper bound
\[
\mathbb{E} \left( \sum_{k=1}^\infty e^{\gamma^* z_{k,t}} (z_{k,t})_+ \right)^{1+\delta} \leq \left( \sum_{k=1}^\infty \mathbb{E} e^{p(1 + \delta) \gamma^* z_{k,t}} (z_{k,t})_+^{p(1 + \delta)} 1_{\{k \leq Y_t\}} \right)^{1/p} \left( \sum_{k=1}^\infty \mathbb{E} Y_t^{q\delta} 1_{\{k \leq Y_t\}} \right)^{1/q}.
\]
It remains to note that
\[
\sum_{k=1}^\infty \mathbb{E} e^{p(1 + \delta) \gamma^* z_{k,t}} (z_{k,t})_+^{p(1 + \delta)} 1_{\{k \leq Y_t\}} = \mathbb{E} \int e^{p(1 + \delta) \gamma^* y} y^{p(1 + \delta)} Z_t(dy) < \infty,
\]
since $p(1 + \delta) \gamma^* < s_\infty$. The proof is complete. \qed

**Proof of Proposition 3.2.** PROOF OF PART (i). Fix $\theta > 0$. Define a point process
\[
\Xi := \sum_{k=1}^{Y_\theta} \delta_{-\gamma^* z_{k,\theta}^*}
\]
and consider a discrete-time branching random walk $(Z_n^{(\theta)})_{n=0,1,2,\ldots}$, where
\[
Z_n^{(\theta)} := \sum_{k=1}^{Y_{n\theta}} \delta_{-\gamma^* z_{k,n\theta}^*}, \quad n = 0, 1, 2, \ldots
\]
The discrete-time branching random walk $(Z_k^{(\theta)})$ has the displacement process $\Xi$ and satisfies the following three conditions:

\[
(3.10) \quad \mathbb{E} \left( \int_{\mathbb{R}} e^{-y} Z_1^{(\theta)}(dy) \right) = 1, \quad \mathbb{E} \left( \int_{\mathbb{R}} e^{-y} y Z_1^{(\theta)}(dy) \right) = 0 \quad \text{and} \quad \mathbb{E} \left( \int_{\mathbb{R}} e^{-y} y^2 Z_1^{(\theta)}(dy) \right) = \theta \Phi''(\gamma^*) < \infty,
\]
where the last two relations are secured by Lemma 3.6. Moreover, Lemma 3.8 yields
\[ E \left( \int_{\mathbb{R}} e^{-y} Z_{1}^{(\theta)}(dy) \right)^{1+\delta} < \infty \quad \text{and} \quad E \left( \int_{\mathbb{R}} e^{-y} y Z_{1}^{(\theta)}(dy) \right)^{1+\delta} < \infty, \]
whence conditions (5.3) in [16] hold. Therefore, Assumption (H) in the same reference holds for the discrete-time branching random walk \((Z_{n}^{(\theta)})_{n=0,1,2,...}\) for every fixed \(\theta > 0\).

By Theorem 5.29 in [16], see also Theorem 1.1 in [2], we have
\[ \sqrt{n} M_{n\theta}(\gamma^{*}) = \sqrt{n} \sum_{k=1}^{\gamma_{\lambda,\theta}} e^{\gamma^{*} z_{k,n\theta}} = \sqrt{n} \int_{\mathbb{R}} e^{-y} Z_{n}^{(\theta)}(dy) \xrightarrow{P} \sqrt{\frac{2}{\pi (\gamma^{*})^{2} \Phi''(\gamma^{*})}} D_{\infty}, \quad n \to \infty, \]
where \(D_{\infty}\) is a.s. positive, because in our settings the process does not extinct with probability one.

For \(t \geq 0\) define
\[ p_{\varepsilon}^{(1)}(t) := P \left\{ \sqrt{t} M_{t}(\gamma^{*}) - \sqrt{\frac{2}{\pi (\gamma^{*})^{2} \Phi''(\gamma^{*})}} D_{\infty} > \varepsilon \right\}. \]
We have proved that for fixed \(\varepsilon > 0\) it holds
\[ p_{\varepsilon}^{(1)}(n\theta) \to 0, \quad n \to \infty, \]
for every \(\theta > 0\). In order to finish the proof of part (i) it remains to show that
\[ \lim_{t \to \infty, t \in \mathbb{R}} p_{\varepsilon}^{(1)}(t) = 0. \]

According to the Croft-Kingman lemma, see Corollary 2 in [12], it is enough to check that \(t \mapsto p_{\varepsilon}^{(1)}(t)\) is continuous from the right, which in turn is equivalent to the continuity from the right of the function
\[ f_{x}^{(1)}(t) := P \left\{ \sum_{k=1}^{\gamma_{t}} e^{\gamma^{*} z_{k,t}} \leq x \right\}, \quad t \geq 0, \]
for every fixed \(x \in \mathbb{R}\). To check the latter statement, note that for \(0 \leq s \leq t\) we have
\[ |f_{x}^{(1)}(t) - f_{x}^{(1)}(s)| \leq P\{\text{there are splits during } [s, t]\} \]
and the right-hand side converges to 0 as \(t \downarrow s\). This completes the proof of part (i).

**Proof of Part (ii).** The claim of part (ii) can be reformulated as follows:
\[ \min_{k=1,...,\gamma_{t}} (-\gamma^{*} z_{k,t}^{0}) - \frac{1}{2} \log t \xrightarrow{P} +\infty, \quad t \to \infty. \]

Fix arbitrary \(M > 0\) and define a function
\[ p_{M}^{(2)}(t) := P \left\{ \min_{k=1,...,\gamma_{t}} (-\gamma^{*} z_{k,t}^{0}) - \frac{1}{2} \log t \leq M \right\}, \quad t \geq 0. \]

By Theorem 5.12 in [16], see also [11, 9], we already know that
\[ \lim_{n \to \infty} p_{M}^{(2)}(n\theta) = 0 \]
for every fixed $\theta > 0$. In order to apply the Croft-Kingman lemma we need to check that 
$t \mapsto p_M^{(2)}(t)$ is continuous from the right. Clearly, it is enough to show that 
$$f_x^{(2)}(t) := \Pr \left\{ \min_{k=1, \ldots, Y_t} z_{k,t} \leq x \right\}, \ t \geq 0$$
is continuous from the right for every fixed $x \geq 0$. This can be done exactly as we did 
before for the function $t \mapsto f_x^{(1)}(t)$. The proof of Proposition 3.2 is complete. \hfill \Box

4. Proof of Theorem 1.4

The key ingredient in the proof is Proposition 3.2 and the following lemma.

**Lemma 4.1.** Assume that $(r_t)_{t \geq 0}$ is an integer-valued random process such that $r_t \P \to \infty$, as 
t $\to \infty$. Further, suppose that for every $t \geq 0$ there is an array $(a_{k,t})_{k=1, \ldots, r_t}$ of a.s. positive 
random weights such that 
$$\sum_{k=1}^{r_t} a_{k,t}^\gamma \P \to a_\infty \quad \text{and} \quad \max_{k=1, \ldots, r_t} a_{k,t} \P \to 0, \ t \to \infty,$$
for some a.s. positive random variable $a_\infty$ and $\gamma \in (0, 2]$. Let $(X_k)_{k \in \mathbb{N}}$ be a sequence of 
independent random variables with common distribution function $F_0$ satisfying $(H_\gamma)$ and 
which are independent of $(a_{k,t})_{k=1, \ldots, r_t}$ and $r_t$ for every fixed $t \geq 0$. Put 
$$S_t := \sum_{k=1}^{r_t} a_{k,t} X_k, \ t \geq 0.$$
Then 
$$\lim_{t \to \infty} \mathbb{E} \exp(i\xi S_t) = \mathbb{E} \hat{g}_\gamma(\xi a_\infty^{1/\gamma}), \quad \xi \in \mathbb{R},$$
where $\hat{g}_\gamma$ is defined by (1.3).

**Proof.** The proof is based on the following asymptotic expansions of the characteristic 
function $\phi_0$ of $X_0$, that are equivalent to the corresponding assumptions of the distribution 
function $F_0$:

- if the case (a) of $(H_1)$ holds, then $\log \phi_0(\xi) = im_0 \xi + o(\xi)$ as $\xi \to 0$;
- if the case (b) of $(H_1)$ holds, then $\log \phi_0(\xi) = -\pi c_0^+ |\xi| + o(\xi)$ as $\xi \to 0$;
- if $(H_2)$ holds, then $\log \phi_0(\xi) = -\frac{\sigma^2}{2} \xi^2 + o(\xi^2)$ as $\xi \to 0$;
- if $(H_\gamma)$ holds with $\gamma \in (0, 1) \cup (1, 2)$, then 
  $$\log \phi_0(\xi) = -k_0 |\xi|^{\gamma} (1 - i\eta_0 \tan(\pi \gamma / 2) \sign \xi) + o(|\xi|^{\gamma}), \quad \xi \to 0.$$ 
Using the above expansions the rest of the proof is standard and relies on the formula 
$$\mathbb{E} \exp(i\xi S_t) = \mathbb{E} \left( \exp \left( \sum_{k=1}^{r_t} \log \phi_0(a_{k,t} \xi) \right) \right), \ \xi \in \mathbb{R}, \ t \geq 0.$$
We will give full details in the case (a) of \((H_1)\). The other cases can be checked similarly. From the equality
\[
E \exp(i \xi S_t) = E \left( \exp \left( \sum_{k=1}^{r_t} (\log \phi_0(a_{k,t} \xi) - im_0 \xi a_{k,t}) \right) \right), \quad \xi \in \mathbb{R}, \quad t \geq 0,
\]
we see that it is enough to check that for every fixed \(\xi \in \mathbb{R}\)
\[(4.2) \quad \sum_{k=1}^{r_t} (\log \phi_0(a_{k,t} \xi) - im_0 \xi a_{k,t}) \xrightarrow{\mathbb{P}} 0, \quad t \to \infty.
\]
Fix \(\varepsilon > 0\). There exists \(x_0(\varepsilon) > 0\) such that
\[
|\log \phi_0(x) - im_0 x| \leq \varepsilon |x|, \quad |x| \leq x_0(\varepsilon).
\]
Therefore, for every fixed \(\varepsilon_0 > 0\)
\[
\mathbb{P} \left\{ \sum_{k=1}^{r_t} |\log \phi_0(a_{k,t} \xi) - im_0 \xi a_{k,t}| > \varepsilon_0 \right\}
\leq \mathbb{P} \left\{ \varepsilon |\xi| \sum_{k=1}^{r_t} a_{k,t} > \varepsilon_0 \right\} + \mathbb{P} \left\{ |\xi| a_{k,t} > x_0(\varepsilon) \right\}.
\]
Sending \(t \to \infty\) and then \(\varepsilon \to +0\) yields \((4.2)\). The proof is complete. \(\square\)

**Proof of Theorem 4.4** Put \(a_{k,t} := t \frac{1}{\gamma^*} e^{\frac{1}{\gamma^*} - \mu(\gamma^*)} \gamma, \quad r_t := y_t, \quad a_\infty := \sqrt{\frac{2}{\pi(\gamma^*)^2 \Phi''(\gamma^*)}} D_\infty, \quad \gamma = \gamma^*, \) and finally
\[
S_t = t \frac{1}{\gamma^*} e^{-\mu(\gamma^*)} \sum_{k=1}^{y_t} e^{\frac{x_{k,t}}{\gamma^*}} X_k, \quad t \geq 0.
\]

From Proposition 3.2 we know that all the assumptions of Lemma 4.1 hold and therefore
\[
\lim_{t \to \infty} E \exp(i \xi S_t) = E \tilde{g}_\gamma \left( \xi \left( \sqrt{\frac{2}{\pi(\gamma^*)^2 \Phi''(\gamma^*)}} D_\infty \right)^{1/\gamma} \right), \quad \xi \in \mathbb{R}.
\]
By Proposition 2.5
\[
E \exp(i \xi S_t) = \phi(t, t \frac{1}{\gamma^*} e^{-\mu(\gamma^*)} \xi)
\]
which proves convergence. It remains to show that \(D_\infty\) satisfies \((1.5)\). Let \(\tau_1\) be the time of the first split in \((Z_t)_{t \geq 0}\), then
\[
Z_t(\cdot) \overset{d}{=} 1_{\{\tau_1 > t\}} \delta_0(\cdot) + 1_{\{\tau_1 \leq t\}} \sum_{k=1}^{N \tau_1} Z^{(k)}_{t-\tau_1}(\cdot - z_{k,\tau_1}),
\]
and therefore

\[ \sqrt{t} M_t(\gamma^*) = \sqrt{t} e^{-\Phi(\gamma^*)t} \int_{\mathbb{R}} e^{\gamma^* y} Z_t(dy) = 1_{\{\tau_1 > t\}} \sqrt{t} e^{-\Phi(\gamma^*)t} \]

\[ + 1_{\{\tau_1 \leq t\}} \sum_{k=1}^{N} \sqrt{t} e^{-\Phi(\gamma^*)(t-\tau_1)} A_k^{\gamma^*} \int_{\mathbb{R}} e^{\gamma^* y} Z_{t-\tau_1}^{(k)}(dy). \]

Sending \( t \to \infty \) yields (1.5) because \( \tau_1 \) has a standard exponential law and is independent of \( (Z_t^{(k)})_{t \geq 0}, k \in \mathbb{N} \). The proof is complete.

\[ \square \]
