ABSTRACT

BACKGROUND AND PURPOSE: We aimed to analyze the clinical outcome after mechanical thrombectomy in patients with premorbid mRS 3 and 4 because there are currently no data on this patient group.

MATERIALS AND METHODS: Between January 2009 and November 2017, all patients with premorbid mRS 3 or 4 undergoing mechanical thrombectomy due to anterior circulation stroke were selected. Good outcome was defined as a clinical recovery to the status before stroke onset (ie, equal premorbid mRS and mRS at 90 days). In addition, mortality at discharge and at 90 days was analyzed.

RESULTS: One hundred thirty-six patients were included, of whom 81.6% presented with premorbid mRS 3; and 18.4%, with premorbid mRS 4. 24.0% of patients with premorbid mRS 4 achieved clinical recovery compared with 20.7% of patients with premorbid mRS 3 (P = .788). However, the proportion of hospital mortality and mortality at 90 days was nonsignificant, but markedly higher in patients with premorbid mRS 4. Multivariate analysis identified low NIHSS scores (OR, 0.92; 95% CI, 0.85–0.99; P = .040), high ASPECTS (OR, 1.45; 95% CI, 1.02–2.16; P = .049), and TICI 2b–3 (OR, 7.11; 95% CI, 1.73–49.90; P = .017) as independent predictors of good outcome.

CONCLUSIONS: Good outcome in patients with premorbid mRS 3 and 4 is less frequent compared with premorbid mRS 0–2. Nevertheless, about 20% of the patients return to their premorbid mRS, which may justify endovascular treatment. The most important predictor of good outcome is successful recanalization.

ABBREVIATION: MT = mechanical thrombectomy

The mRS is a commonly used outcome measure in stroke treatment (Table 1). In addition, it is also used to assess the premorbid/prestroke disability of patients with stroke. Most randomized controlled trials on mechanical thrombectomy (MT) published in recent years excluded patients with premorbid mRS > 1. Only the Endovascular Therapy Following Imaging Evaluation for Ischemic Stroke 3 (DEFUSE-3) included patients with premorbid mRS 0–2. Therefore, the American Heart Association/American Stroke Association briefly addressed this issue in their latest guidelines, stating that MT in patients with premorbid mRS > 1 has uncertain benefits and further randomized controlled trials are necessary.

Nevertheless, many stroke centers regularly perform MT in patients with premorbid mRS 2 (ie, in patients with slight disability but functional independence before stroke onset). However, there are uncertainties about the efficacy of thrombectomy in patients with moderate and moderately severe disability (ie, premorbid mRS 3 and 4). To our knowledge, there are no randomized controlled trials or cohort studies addressing this issue. Therefore, we analyzed clinical outcomes of patients with anterior circulation stroke and premorbid mRS 3 and 4 undergoing MT at our comprehensive stroke center.

MATERIALS AND METHODS

Patient Selection

Between January 2009 and November 2017, all patients with stroke undergoing MT at our institution were prospectively collected in a stroke data base. For these patients, we performed a single-center, observational, retrospective cohort study. Inclusion criteria were the following: 1) occlusion of the intracranial internal carotid artery or M1 or M2 segment of the middle cerebral artery, and 2) premorbid mRS 3 or 4. Our institutional review board approved this study. Informed consent was waived.

Treatment

The decision for treatment was made in consensus between the neurologist and neuroradiologist on duty, mostly depending on...
the imaging findings and the probable or explicit patient preference. Patients received intravenous thrombolysis, if eligible. Patients underwent MT with the intention to achieve TICI 2b–3.

**Image Analysis**

The baseline ASPECTS was determined on either nonenhanced CT scans or diffusion-weighted images before MT by a radiologist. The occlusion site was determined on digital subtraction angiograms. Successful recanalization was defined as TICI 2b–3 on the final angiogram.

**Outcome Measures**

The primary outcome parameter was good clinical outcome defined as a clinical recovery to the status before stroke onset (ie, premorbid mRS and mRS scores at 90 days were equal). Poor outcome was defined as any worsening of the mRS score at 90 days. Secondary outcome parameters were hospital mortality and mortality at 90 days.

**Statistical Methods**

R Version 3.4.3 and RStudio Version 1.1.414 (RStudio; https://www.rstudio.com/) were used for statistical analysis. Numeric baseline characteristics were described in medians and interquartile ranges or means and SDs. Patients achieving good clinical outcome were compared with those with poor outcome in a univariate analysis. All variables with \( P < .1 \) were included in a multivariate binary logistic regression analysis to identify independent predictors of good clinical outcome. Comparisons between groups were performed using Student \( t \) tests or the Mann-Whitney \( U \) test for continuous data and the Fisher exact test for categorical variables. The Kruskal-Wallis test was used for group comparisons. A \( P \) value \(< .05 \) was considered statistically significant.

**RESULTS**

Of 1223 patients within the above-mentioned timeframe who underwent MT, a total of 136 consecutive patients (11.1%) met the inclusion criteria of this study. Of these, 111 patients (81.6%) presented with a premorbid mRS of 3 and 25 patients (18.4%) presented with a premorbid mRS of 4. The mean age of our cohort was 80.6 ± 10.1 years.

Of these 136 patients, 12 (8.8%) were treated with aspiration only, 111 (81.6%) were treated using stent retrievers under proximal aspiration, and 13 (9.6%) were treated with aspiration attempts and stent-retriever attempts under proximal aspiration.

**Good-versus-Poor Outcome**

In our cohort, 21.3% achieved good clinical outcome—that is, the mRS at 90 days after stroke onset was the same as the premorbid mRS. First, we compared patients achieving good clinical outcome with those achieving poor outcome (78.7%). Age, proportion of risk factors, premorbid mRS, rate of intravenous thrombolysis treatment, and time from onset to groin puncture and from groin puncture to TICI were similar in both groups (Table 2).

Multivariate analysis identified low NIHSS scores (OR, 0.92; 95% CI, 0.85–0.99; \( P = .040 \)), high ASPECTS (OR, 1.45; 95% CI, 1.02–2.16; \( P = .049 \)), and TICI 2b–3 (OR, 7.11; 95% CI, 1.73–49.90; \( P = .017 \)) as independent predictors of good clinical outcome. The occlusion site was not an independent predictor. Nonetheless, patients with good outcome had a significantly lower rate of ICA occlusion (6.9% versus 27.1%, \( P = .024 \)) and a significantly higher rate of M2 occlusion (41.4% versus 16.8%, \( P = .010 \)). The proportion of M1 occlusions was nonsignificantly smaller in patients with good outcome (51.7% versus 58.9%, \( P = .530 \)) (Table 3).

**Premorbid mRS 3 versus 4**

Finally, we compared clinical outcomes in patients with premorbid mRS 3 and 4. The rate of successful recanalization was similar in both groups. Ninety-day mRS was significantly higher in patients with
premorbid mRS 4 compared with mRS 3 (median mRS of 6 versus mRS 5, \( P < .001 \)). The proportion of good outcome was slightly but nonsignificantly higher in patients with premorbid mRS 4 (24.0\% versus 20.7\%, \( P = .7877 \)). Hospital mortality and mortality at 90 days were nonsignificantly but markedly higher in patients with premorbid mRS 4 (24.0\% versus 15.3\%, \( P = .231 \); and 64.0\% versus 46.8\%, \( P = .183 \)) (Table 4).

### DISCUSSION

In this study, we analyzed clinical outcome in a stroke cohort that has been excluded from previous randomized controlled trials on neurothrombectomy: patients with stroke with moderate and moderately severe premorbid disability.

As a main finding, about one-fifth of our cohort achieved good clinical outcome: These patients returned to their prestroke condition 90 days after stroke onset without the need for further assistance or additional costs. Indeed, worsening of clinical status is associated with increasing health care costs. Dewilde et al.\(^6\) for instance, report that mRS 4 at 90 days after stroke onset was associated with significantly higher care costs compared with mRS 3 ($4008 versus $1639, \( P < .001 \)). Therefore, MT can prevent an increase of long-term health care costs in patients with elevated premorbid mRS.

The relatively low rate of good outcome compared with the results of thrombectomy in premorbid mRS 0–2 might be attributed to old age and age-related frailty. While mean age in our cohort was 80.6 years, median age in the Highly Effective Reperfusion evaluated in Multiple Endovascular Stroke Trials (HERMES) meta-analysis was 68 years.\(^2\)

Hospital mortality and mortality at 90 days were nonsignificantly higher in patients with premorbid mRS 4 compared with premorbid mRS 3. This difference is probably not significant due to the low number of patients with premorbid mRS 4 in our cohort (\( n = 25 \)). A possible explanation is that treatment in patients with premorbid mRS 4 might be terminated earlier compared with patients with premorbid mRS 3.

Successful recanalization was the most powerful predictor of good outcome (OR, 7.11; 95\% CI, 1.73–49.90; \( P = .0171 \)). Furthermore, increasing stroke severity (high NIHSS score) and increasing infarct size (low ASPECTS) were associated with lower chances of achieving good outcome in our cohort. This finding has been previously described by Hui et al.\(^8\). Although both parameters were statistically independent predictors, they might nevertheless be related to the occlusion site because proximal occlusions are usually associated with worse outcome compared with distal occlusions.\(^5\) In our cohort, M2 occlusions were more frequent in patients with good outcome, and ICA occlusions were more frequent in patients with poor outcome.

Our study has limitations, mainly due its retrospective non-randomized design. There might be a selection bias because patients with stroke with premorbid mRS 3 and 4 not undergoing MT were not included in this study. Because we did not have a control group, it is not possible to determine the benefit of MT compared with best medical care. MT may possibly have little benefit in patients with premorbid mRS 3 and 4. Also, only a small group of 25 patients with premorbid mRS 4 were analyzed in this study. Moreover, using the mRS for prestroke assessment is controversial because the mRS is primarily designed to assess post-treatment clinical status. Fearon et al.\(^10\) have reported that interobserver reliability and validity of premorbid mRS are limited. In some cases, assessing the premorbid status is not even possible because of missing or incorrect information. Nonetheless, mRS is the most frequently used measure to assess the premorbid status of patients with acute stroke.

### CONCLUSIONS

Overall, good clinical outcome, defined as unchanged disability, is less frequent in premorbid mRS 3 and 4 compared with patients with premorbid mRS 0–2. Nevertheless, about 20\% of the patients return to their premorbid mRS, which may justify endovascular treatment. Because we did not have a control group, it is not possible to determine the benefit of MT compared with best medical care. MT may possibly have little benefit in patients with premorbid mRS 3 and 4. The most important predictor of good outcome is successful recanalization.
