Abstract: The present study aims to investigate for the first time the possible therapeutic effect of four novel synthesized thiosemicarbazones (TSCs) compounds against cadmium toxicity in rats. The experimental animals were assigned into two main groups, control and cadmium chloride (CdCl2) (50 mg/kg body weight) treated group. CdCl2 treated group then subdivided into five subgroups, vehicle subgroup, TSC1, TSC2, TSC3 and TSC4 treated subgroups. Cd administration resulted in a significant increase in aspartate aminotransferase (AST), alanine transaminase (ALT), and alkaline phosphatase (ALP), creatinine, urea, and uric acid levels. Cd intoxication significantly increased the level of the liver and kidney malondialdehyde (MDA) and decreased levels of reduced glutathione (GSH) and catalase (CAT) in the liver and kidney tissues. Cotreatment with the four thiosemicarbazones derivative compounds significantly reversed the hepatorenal alterations induced following cadmium administration. It can be concluded from the aforementioned investigation that the synthesized TSCs derivatives might be acting through two main mechanisms, the 1st one is antioxidant and the 2nd one is chelating therapy.

Keywords: cadmium, thiosemicarbazones, liver function, kidney function, oxidative stress

Contamination of food and feedstuffs with heavy metals represent a major health problem in animals and human (1). Cadmium (Cd) is a common food contaminant and considered one of the most widely spread environmental pollutants (2). Besides, Cd is a bio-hazard with no physiological function in the human body (3). Cd is one of the most extensively distributed toxicants due to its excessive use in modern lifestyles (4). Owing to increasing use in plating, pigments, metal coating, plastic manufacturers, and nickel-Cd batteries, it is likely that through both deliberate application and accidental release, Cd will find its way into aquatic, terrestrial, and atmospheric environments (5). Emission of Cd from industrial activities, agricultural practices using contaminated phosphate fertilizers and sewage sludge, and also tobacco smoke leads to environmental pollution (6).

The potential impact of Cd toxicity has attracted special attention due to its long half-life which leads to its accumulation in living tissues for long periods (3). Elucidating the possible correlation between environmental pollutants and stress-related disease conditions in animals needs a great effort. There has been a wealth of studies that describe oxidative stress (OXS) during Cd toxicity, with evidence of reactive oxygen species (ROS) production (7). The liver and kidney are the most targeted organs for Cd toxicity (2). Hepatotoxicity is the main reason for Cd acute lethality consequent to Cd transportation (8). Cd is a well-studied nephrotoxic metal element and its toxicity is represented through the structural damage of kidneys and changes in the excretory function (7).

The predicted increase in the incidence of Cd toxicity justifies a search for opportunities to prevent its adverse effects. For the therapeutic strategies of cadmium toxicity, it is important to find a safe compound that can block its injuries. Chelation therapy is the most commonly used therapeutic strategy for heavy metal poisoning. Chelation therapy plays an important role in modern medicine and pharmacology and has been the mainstay to remove toxic metals from human organs and tissue (9). Unfortunately, the

* Corresponding author: e-mail: ayman81125@hotmail.com
current pharmacological therapy used for Cd toxicity has serious deleterious effects. Also, to our knowledge, there are no approved chelation therapies for Cd toxicity for clinical use. A Schiff-base compound like hydrazones and thiosemicarbazones (TSCs) are widely used in medicinal chemistry due to their wide biological activities (10). The wide spectrum of biological properties shown by TSCs derivatives attracts the researchers’ interest (11). The development of safe and efficient strategies against Cd toxicity is, therefore, an area of ongoing research. Thereby, the present study was designed to investigate the possible therapeutic effect of four novel synthesized TSCs compounds against Cd toxicity in rats. The present study extended to elucidate the mechanism of the studied TSCs derivatives in Cd detoxification.

**MATERIAL**

**Material**

Thiosemicarbazone (TSCs) derivatives (Figure 1) were synthesized by Dr. Ahmed El-Sheerf, Chemistry Department, Faculty of Science, Cairo University. Cadmium chloride (CdCl₂) was dissolved in distilled water. The selected dose of CdCl₂ was selected on the basis of previous studies (12, 13). Cadmium chloride was administered orally because it is the main mode of exposure to cadmium in humans and animals.

### In vitro antioxidant

The free radical scavenging activities of each synthesized TSC derivative were analyzed by the 1,1-diphenyl-2-picryl hydrazyl (DPPH) assay (14). The absorbance of sample, blank sample, and control was measured at 517 nm, after 30 min incubation in the dark at room temperature, using Thermo Scientific Evolution 201 UV-Visible Spectrophotometer. The experiment was done in triplicates. The percentage of antioxidant activity was calculated as follows:

\[
\text{Antioxidant activity, AA} \% = 100 - \left[ \frac{(\text{Abs sample} - \text{Abs blank}) \times 100}{\text{Abs control}} \right]
\]

### Experimental animals

Male conventional Wistar rats (outbred) strain, weighing 150-160 ± 5 g were used (National Research Center, Dokki, Egypt). During the period of the acclimation (7 days) and the experimental periods, the rats were fed standard rodent food pellets (Agricultural-Industrial Integration Company, Giza, Egypt) *ad libitum*. Tap water was also provided *ad libitum* and renewed every day. Rats were grouped and housed in polyacrylic cages (six animals per cage) and supplied with sawdust, bedding materials, and Kleenex tissues as nesting material plus two wooden cubes. The room was maintained at a constant temperature (22°C – 25°C) and 12 : 12 h light : dark. The room also schedules with the white light on

![Figure 1. Structural formulae of the synthesized thiosemicarbazone derivatives.](image-url)
between 02:00 and 14:00 h. Experimental protocols and procedures used in this study were approved by the Cairo University, Institutional Animal Care and Use Committee (CU-IACUC) (Egypt), (approval no. Cu/F/1/86/18).

Estimation of LD\textsubscript{50} based on in vitro IC\textsubscript{50} value

To reduce the number of animals used in acute oral toxicity testing, cytotoxicity data (IC\textsubscript{50}) can be used to determine the starting dose for in vivo testing by applying the standard regression between IC\textsubscript{30} and acute oral LD\textsubscript{50} values in the Register of Cytotoxicity (RC) (Spielmann et al., 1999; ICCVAM, 2006). As the molecular weight of the synthesized TSCs compounds is identified, thereby the estimated LD\textsubscript{50} was determined using the following equation:

\[ \log (LD_{50}) = 0.435 \times \log (IC_{50}) + 0.625 \]

The LD\textsubscript{50} values of rats were estimated from the IC\textsubscript{50} values obtained from the in vitro cytotoxic NRU assay on HepG2 (unpublished data) because these cells have the highest cytotoxic sensitivity to the synthesized TSCs compounds (15).

Acute toxicity study

Acute oral toxicity was evaluated by following Organization of Economic Co-operation and Development (OECD) guidelines 423- Fixed-Dose Procedure (FDP), where the concentration range is 5, 50, 300, and 2000 mg/kg (upper limit of 2000 mg/kg) (OECD, 2001). The estimated LD\textsubscript{50} relevant to each studied compound was used as the starting dose for FDP. Observation of Wellness parameters of animals were observed continuously during the first 30 min and the first 4 hours after dosing. Animals were also observed for the next 24 hours and then daily thereafter, for 14 days. All observations were systematically recorded with individual records being maintained for each animal. Changes in wellness parameters were compared with that of control animals.

Experimental design

Thirty-six male Wistar rats were assigned into two main groups, control (6 rats/group) and CdCl\textsubscript{2} treated group (30 rats/group). Animals in CdCl\textsubscript{2} treated group was administered CdCl\textsubscript{2} at a dosage of 50 mg/kg body weight once every two days and concurrently treated with the synthesized TSC derivative for 21 consecutive. This group was divided into 5 subgroups (6 rats/subgroup) as follow:

- **Subgroup I (Vehicle group)**: Rats of this subgroup administered dimethyl sulfoxide (DMSO) orally.
- **Subgroup II (CdCl\textsubscript{2} + TSC\textsubscript{1})**: Animals of this subgroup were treated orally with CdCl\textsubscript{2} and TSC\textsubscript{1} (200 mg/kg body weight).
- **Subgroup III (CdCl\textsubscript{2} + TSC\textsubscript{2})**: Animals of this subgroup were treated orally with CdCl\textsubscript{2} and TSC\textsubscript{2} (200 mg/kg body weight).
- **Subgroup IV (CdCl\textsubscript{2} + TSC\textsubscript{3})**: Animals of this subgroup were treated orally with CdCl\textsubscript{2} and TSC\textsubscript{3} (200 mg/kg body weight).
- **Subgroup V (CdCl\textsubscript{2} + TSC\textsubscript{4})**: Animals of this subgroup were treated orally with CdCl\textsubscript{2} and TSC\textsubscript{4} (30 mg/kg body weight).

Animals handling and sample preparation

After 21 days, animals were euthanized under deep anesthesia with sodium pentobarbital (100 mg/kg body weight). Blood samples were collected by cardiac puncture in EDTA tubes for hematological and biochemical parameters. After the hematological measurement, blood samples were centrifuged at 3000 rpm for 20 min. Plasma samples were stored at -20°C until used for biochemical assays. The liver and kidney were dissected out immediately and divided into two parts; the first part was suspended in 10% formal saline for fixation and preparation for histological processing. While the second part is stored at -80°C for biochemical analysis. Liver and kidney tissues were homogenized (10% w/v) in ice-cold 0.1 M Tris-HCl buffer (pH 7.4). The homogenate was centrifuged at 3000 rpm for 15 min at 4°C and the resultant supernatant was used for biochemical analysis. Liver and kidney slices were fixed in 10% formal saline and embedded in paraffin wax blocks. Sections of 5 μm thick were stained with hematoxylin and eosin (H&E) then examined under a light microscope for determination of pathological changes.

Hematological parameters

A complete blood count (CBC) was performed on the blood sample using the Coulter-Counter technique that was earlier described by Coulter (16). Blood samples were placed in Swelab’s fully automatic auto- counter, model AC920EO+ (Cape Town, South Africa).

Biochemical analysis

The appropriate kits (Bio-Diagnostic, Dokki, Giza, Egypt) were used for the determination of liver enzyme parameters aspartate aminotransferase (AST), alanine transaminase (ALT), and alkaline phosphatase (ALP). The same kits were used to determine the kidney function parameters as creatinine, urea, and uric acid.
Oxidative stress parameters

The appropriate kits (Bio-Diagnostic kits, Bio-Diagnostic, Dokki, Giza, Egypt) were used for the determination of malondialdehyde (MDA) (17), reduced glutathione (GSH) (18), and catalase (CAT) were detected according to the method described by Aebi (19).

Statistical analysis

Values were expressed as means ± SE. To evaluate differences between the groups studied, a one-way analysis of variance (ANOVA) with Duncan post hoc test was used to compare the group means, and P < 0.05 was considered statistically significant. SPSS, for Windows (version 15.0) was used for the statistical analysis.

RESULTS AND DISCUSSION

In vitro antioxidant

Cadmium is a toxic metal that promotes early oxidative stress (20). Chelation therapy is currently the primary treatment modality in the alleviation or prevention of Cd toxicity. Ethylenediaminetetraacetic acid (EDTA) (21) and Dimercaprol (22) are the most important chelating agents that have been used during Cd toxicity. However, the development of acute renal failure subsequent to EDTA and Dimercaprol administration during Cd toxicity is the main obstacle for their use (21, 23). Therefore, the development of novel chelating agents would play a key role in the treatment of Cd toxicity. For the therapeutic strategies of hepatorenal injury following Cd toxicity in living organisms, it is important to find a complementary antioxidant compound that is able to block this injury. The present study proved the potential therapeutic role of the four novel thiosemicarbazones (TSCs) derivatives against Cd hepatotoxicity and nephrotoxicity in rats. The results of the DPPH scavenging activity of the four synthesized TSC derivatives are shown in Figure 2. The radical scavenging activities were estimated by comparing the percentage of inhibition of DPPH radical by the four synthesized TSC derivatives. The present results showed that TSC2 with methyl substitution showed the least DPPH scavenging activity as compared to the remaining derivatives. Figure 1 also showed that TSC1 and TSC4 with ethyl and phenyl substitutions showed the same antioxidant activity.

Estimated LD50 based on in Vitro HepG2 and MCF-7 Cell Lines

The estimated LD_{50} was determined according to ICCVAM (2006) using the following equation: \( \log (LD_{50}) = 0.435 \times \log (IC_{50}) + 0.625 \). Data recorded in Table 1, showed that the estimated LD_{50} for the studied four synthesized TSCs compounds using the IC_{50} of the HepG2 cell lines were 168.32, 131.5, 83.65, and 45.9 respectively. Regarding the estimation of LD_{50} for the studied four synthesized TSCs compounds using the IC_{50} of the using MCF-7 cell Lines, data recorded in Table 2 showed that LD_{50} for the studied four synthesized TSCs compounds were 223.9, 260, 314.39, and 195.83 respectively.

Acute toxicity of synthesized thiosemicarbazone compounds

Results indicated that the TSCs compound number I, II and III up to a dosage of 2000 mg/kg; p.o. did not produce any mortality. However, TSCs compound number IV has been found toxic at 2000 mg/kg body

Figure 2. Antioxidant activity of the four synthesized TSC derivatives. Each vertical column represents the mean ± SEM change of three replications.
weight of experimental animals as in the first 4 hours of observation 2/3 morbidity was observed and in the next 24 hours of observation mortality in the ratio 2/3 were found (Table 3). No significant changes were observed in body weight and wellness parameters used for evaluation of toxicity for TSCs compound number I, II, and III. Thereby, the LD$_{50}$ value was found to be more than 2000 mg/kg body weight. For TSCs compound number IV, the LD$_{50}$ value was found to be more than 300 mg/kg body weight but less than 2000 mg/kg body weight.

### Effect of the thiosemicarbazone derivatives on the different hematological parameters in Cd-intoxicated rats

Data recorded in Table 4 indicated that Cd intoxication caused a significant increase ($P < 0.05$) in WBCs count as compared to the control group. On

the other hand, the intoxication of rats with Cd, induced significant reduction (P < 0.05) in the levels of RBCs, PCV, HB, MCV, MCH, MCHC, and Platelets as compared to control groups. However, concurrent treatment with the four TSCs derivatives caused significant restoration in the level of all studied hematological parameters (Table 4).

Effect of the thiosemicarbazone derivatives on liver function parameters in Cd-intoxicated rats

The liver is prone to damage by various noxious compounds and poisonous products due to biotransformation and storage of numerous xenobiotics that enter the body from various sources. The liver is the primary target organ of Cd toxicity following its ingestion. Determination of enzyme levels such as serum AST, ALT, and ALP is largely used during the assessment of liver damage by Cd (24). Figure 3 a, b, and c illustrate the effect of the four TSCs derivatives on some liver function parameters in the control and treated groups against Cd-induced hepatic toxicity in male rats. The recorded results indicated that Cd intoxication caused a significant increase (P < 0.05) in the activities of AST, ALT, and ALP as compared to the control group. Hepatic dysfunction was the most common regimen-related toxicity reported during Cd toxicity. It has been reported that Cd intoxication induced local ischemia in the parenchyma due

Values are given as mean ± SEM for 6 rats in each group. Each value not sharing a common letter superscript is significantly different (P < 0.05).

Figure 3. The protective influence of the four thiosemicarbazone derivatives on alanine (ALT) (a), aspartate (AST) (b) aminotransaminase, and alkaline phosphatase (ALP) (c) activities in Cd-intoxicated rats. Values are given as mean ± SEM for 6 rats in each group. Each value not sharing a common letter superscript is significantly different (P < 0.05).
to the extrusion of damaged cells into the capillary lumen (25). Furthermore, Cd hepatotoxicity involved activation of Kupffer cells, which directly damage hepatocytes via the release of a variety of cytotoxic mediators (26). The present study confirmed the findings of (27) and (28), who explained elevation in the serum enzymes AST, ALT, and ALP to direct toxic effect of the Cd, ischemia, and inflammatory injury following exposure of hepatocytes to Cd. Concurrent treatment with TSC1, TSC2, TSC3, and TSC4 significantly (P < 0.05) decreased the activities of the studied enzymes as compared to the Cd-intoxicated group. However, obtained results also show that TSC3 and TSC4 showed significant (P < 0.05) reduction in the activities of AST, ALT, and ALP as compared to TSC1 and TSC2 (Figure 3 a, b and c). In accordance with the report of Athmouni et al. (27), the administration of four novels TSCs in the present study showed a protective effect against Cd-induced hepatic dysfunction through decreasing the activities of AST, ALT, and ALP, showing its potential to maintain the normal functional status of the liver.

Effect of the thiosemicarbazone derivatives on kidney function parameters in Cd-intoxicated rats

The primary organs involved in the elimination of Cd metal are the liver and kidney (24). Data recorded in Figure 4 a, b, and c illustrated that Cd administration caused a significant increase (P < 0.05) in the levels of creatinine, urea, and uric acids as compared to the control group. During heavy metal toxicity, the kidney is a target organ due to its capability to reabsorb and concentrate divalent ions and metals. Chronic kidney disease (CKD) is a common complication disease that is accompanied by failing organ function leading to the accumulation of a series of compounds (29). In conjunction with the finding of (30), the results of the present study showed that Cd intoxication induced marked alteration in renal functions as manifested by a significant increase in the kidney function markers, serum creatinine, urea, and uric acid. The increased levels in serum kidney function markers may be due to chronic inflammation, fibrosis, and renal failure (31), which developed due to reabsorption of both the protein-bound (non-diffusible) and complex/ionized (diffusible) forms of heavy metals (8). In addition, the elevation of serum levels of uric acid following Cd intoxication could confirm the presence of kidney injury caused by the reduction in glomerular filtration rate (GFR) which was confirmed by the histopathological examination of the kidney. Moreover, (32) showed that Cd intoxication induced features of hepatorenal syndrome, including a significant increase in the serum creatinine, and reductions in creatinine clearance, water excretion, and urinary sodium concentration. It has been demonstrated that oxidative stress and mitochondrial damage are among the fundamental molecular mechanisms of Cd nephrotoxicity (33). Meanwhile,
the possibly enhanced production of the reactive oxygen species could be renal toxic consequently impairing the functional capacity of the kidney (7). The present study showed that treated rats with all studied TSCs derivatives showed a significant decrease in serum creatinine, urea, and uric acid concentrations, which highlight their therapeutic efficacies in alleviating nephrotoxicity induced by Cd.

The present study also affirmed that both TSC3 and TSC4 showed an efficient improvement in liver and kidney function parameters. This improvement may be due to a contributory self-healing mechanism of TSC3 and TSC4 that restoring the liver and kidney structure and function. Histopathological observation of the tissues had directly supported this conclusion (Figure 5 and 6).

Figure 5. Photomicrograph of hematoxylin and eosin-stained liver sections from control (A), Cd (B), TSC1 (C), TSC2 (D), TSC3 (E), and TSC4 (F) treated rats. Histopathological examination of the control rat’s liver showed apparently normal histological findings of hepatocytes (H) and blood sinusoids (S) (Figure 5A). On the other hand, an examination of liver sections of Cd-treated rats demonstrated necrosis (N), adipocytes (A), and severe destructive changes in hepatic architecture (Figure 5B). However, an examination of liver sections of TSC1 and TSC2 treated groups showed moderate to mild degenerated changes in hepatocytes and many adipocytes (Figure 5C and D). The liver of TSC3 and TSC4 treated rats demonstrated normal hepatocyte and moderately improved the hepatic architecture (Figure 5E and F).
Effect of the thiosemicarbazone derivatives on some oxidative parameters in Cd-intoxicated rats

The present investigation served to determine potential correlations between Cd intoxication and oxidative stress in the liver and kidney of rats. Data recorded in Table 5 showed a significant increase (P < 0.05) in the levels of liver and kidney MDA subsequent to Cd administration. On the other hand, Cd intoxication caused a significant decrease (P < 0.05) in the levels of liver and kidney GSH and CAT. It is well known that the critical event in cadmium-induced hepatotoxicity is the impairment of the antioxidant defense system. In conjunction with the

Figure 6. Photomicrograph of hematoxylin and eosin-stained kidney sections from control (A), Cd (B), TSC1 (C), TSC2 (D) TSC3 (E), and TSC4 (F) treated rats. Microscopic examination of the kidney of the control group showed a normal appearance of the tissue where, glomeruli (G) appear as dense tufts of capillaries enclosed in the outer layer of Bowman capsules, urinary space (U), and renal tubules (R) (Figure 6A). The kidney of Cd-treated rats showed severe shrinking and degeneration of glomeruli, degeneration, and necrosis in the epithelial lining of the renal tubules (N), interstitial mononuclear inflammatory cells infiltration (F), and cystic dilatation of the renal tubules (S) (Figure 6B). The kidney of TSC1 and TSC2 treated groups showed mild degeneration in renal tissue architecture, as compared to Cd treated group (Figure 6C and D). Kidney sections of the TSC3 and TSC4 treated group demonstrated healthy renal tissues (Figure 6E and F).
reports of (34) and (35), data from the present investigation reflects that oxidative stress in the liver and kidney is a common feature of Cd toxicity. One of the highly reactive metabolic products that are produced as the result of a series of reactions due to lipid peroxidation is MDA. In consonance with the report of (34) and (35), the present study showed a significant increase in MDA levels in the liver and kidney following Cd toxicity in rats which may suggest enhanced lipid peroxidation leading to tissue damage and failure of antioxidant defense mechanisms. It was reported that exposure to Cd is characterized by the depletion of tissue and circulating non-enzymatic antioxidants including GSH (36). Moreover, the concomitant depletion in the level of GSH with an increment of MDA levels could support the notion that depletion of the liver and kidney GSH after Cd-induced hepatorenal injury is one of the major factors that permit lipid peroxidation and subsequent tissue damage. Inside the living organisms detoxification of cadmium occurs through the formation of Cd-thiol complexes inside the cell which can interpret the reduction in GSH level after Cd intoxication (37). However, a decrease of lipid peroxidation-mediated oxidative stress may be a potential and effective strategy for the prevention and treatment of hepatic failure during Cd toxicity. The present study confirmed the findings of (38) and (39), who reported that TSCs derivatives significantly decreased MDA and increased GSH levels following Cd administration suggesting that their therapeutic mechanism may be due to their antioxidant activity. The biological actions of different TSC compounds are based on their ability to chelate metal ions (40). It was reported that the excellent metal ion chelating capacity of the TSC molecule is due to the presence of amide, imine, and thione groups (41). Generally, the position and type of substituent on the TSC backbone have a strong impact on the overall properties and stability, as well as its biological activity. Herein, data recorded suggested that the substituents on TSC molecules had a profound effect on their antioxidant activity in the order of TSC < TSC < TSC < TSC. It is clear that the TSC and TSC-bearing—ethyl and phenyl substitutions showed the highest antioxidant activity as compared to the remaining compounds. The present study affirmed the report of (42), which reported that compounds containing aromatic or phenolic rings showed the most effective antioxidant activity by donating \( \text{H}^+ \) to the free radicals formed during oxidation (42). Taking into consideration the relation between Cd toxicity and oxidative stress on one hand, and the relation between Cd concentration in the tissues and toxicity, on the other hand, the present investigation aimed to evaluate the mechanism of action by which the studied TSCs derivatives perform during Cd detoxification.

**CONCLUSION**

It can be concluded from the aforementioned investigation that the synthesized TSCs derivatives might be acting through two main mechanisms, the 1st one is antioxidant and the 2nd one is chelating therapy. The antioxidant mechanism is already confirmed through the reduction of lipid peroxidation and the improvement of the antioxidant status of the treated rats. Regarding the chelation effect of the synthesized TSCs derivatives can also be confirmed through the significant reduction in the level of Cd contents in the liver and kidney especially after treatment with TSC and TSC derivatives.

**Conflict of interest**

The authors report no conflicts of interest.

**Table 5. Protective influence of the four thiosemicarbazone derivatives on some oxidative stress parameters in Cd-intoxicated rats.**

| Parameter       | Organ   | Control    | Experimental groups |
|-----------------|---------|------------|---------------------|
|                 |         |            | Vehicle  | TSC     | TSC     | TSC     | TSC     |
| MDA (nmol/g Tissue) | Liver   | 2.64 ± 0.07<sup>a</sup> | 5.27 ± 0.20<sup>b</sup> | 4.64 ± 0.12<sup>c</sup> | 4.45 ± 0.07<sup>d</sup> | 3.45 ± 0.20<sup>e</sup> | 3.14 ± 0.07<sup>f</sup> |
|                 | Kidney  | 2.72 ± 0.07<sup>a</sup> | 3.98 ± 0.07<sup>d</sup> | 3.90 ± 0.04<sup>e</sup> | 3.78 ± 0.05<sup>f</sup> | 3.25 ± 0.05<sup>g</sup> | 3.04 ± 0.14<sup>h</sup> |
| GSH (g/mg Tissue) | Liver   | 11.35 ± 0.06<sup>d</sup> | 7.93 ± 0.15<sup>ac</sup> | 8.60 ± 0.07<sup>a</sup> | 8.85 ± 0.08<sup>b</sup> | 9.46 ± 0.18<sup>c</sup> | 9.99 ± 0.08<sup>d</sup> |
|                 | Kidney  | 10.56 ± 0.11<sup>d</sup> | 6.63 ± 0.03<sup>ac</sup> | 7.72 ± 0.07<sup>a</sup> | 7.77 ± 0.12<sup>b</sup> | 9.81 ± 0.16<sup>c</sup> | 9.91 ± 0.09<sup>d</sup> |
| CAT (U/g Tissue)  | Liver   | 7.62 ± 0.07<sup>a</sup> | 2.14 ± 0.08<sup>c</sup> | 2.61 ± 0.10<sup>c</sup> | 2.71 ± 0.04<sup>b</sup> | 4.45 ± 0.06<sup>g</sup> | 6.14 ± 0.10<sup>d</sup> |
|                 | Kidney  | 5.22 ± 0.04<sup>a</sup> | 1.94 ± 0.10<sup>d</sup> | 2.23 ± 0.07<sup>e</sup> | 2.43 ± 0.03<sup>b</sup> | 3.49 ± 0.12<sup>cd</sup> | 4.55 ± 0.04<sup>cd</sup> |

Values are given as mean ± SEM for 6 rats in each group. Each value not sharing a common letter superscript is significantly different (P < 0.05).
