GALOIS GROUPOID AND CONFLUENCE OF DIFFERENCE EQUATIONS

GUY CASALE AND DAMIEN DAVY

Abstract. In this article we compute Galois groupoid of discret Painlevé equations. Our main tool is a semi-continuity theorem for the Galois groupoid in a confluence situation of a difference equation to a differential equation.

1. Introduction

The aim of this article is to determine Galois groupoids of some discrete dynamical systems \( \Phi : M \to M \). The phase space \( M \) is an algebraic variety and \( \Phi \) is a rational dominant map. Galois groupoid is the “differential algebraic” envelope of \( \Phi \), it describes the richest algebraic geometric structure (see [Gro88]) invariant by \( \Phi \).

For linear differential equation, E. Picard [Pic87], E. Vessiot [Ves04] and later E.R. Kolchin [Kol73] developed a Galois theory. To an order \( n \) linear differential equation with coefficient in the differential field \((\mathbb{C}(x), \frac{d}{dx})\) is associated an algebraic sub-group of \( \text{GL}_n(\mathbb{C}) \). This group measures algebraic relations between a basis of solutions and their derivatives. This theory interacted with many different areas of mathematics see [Ber92] or [vdPS03]. A discrete analog was proposed by Franke [Fra63] for linear difference equations (see also [vdPS97]).

In [Mal01], a similar object was defined by B. Magrange for foliations, including nonlinear differential equations. Malgrange called it the Galois groupoid of the foliation. In the present article, we present an extension of this definition to different dynamical systems. Galois groupoid of a rational dominant map is defined and first examples are studied in [Cas06] and [Gra11]. Let us give a quick, unformal and non complete definition, (see section 2 for the formalisation).

Let \( B \) be a smooth irreducible algebraic variety with en rational dominant self map \( \sigma : B \to B \). It corresponds to a difference field of rational functions \((\mathbb{C}(B), \sigma^*)\). Let \( \Phi : M \to M \) be a smooth irreducible algebraic variety with a projection \( \pi : M \to B \) and \( \Phi : M \to M \) a rational dominant lift of \( \sigma \). The different equation associated to these datas is the equation \( y \circ \sigma = \Phi \circ y \) on local holomorphic sections of \( \pi, y : U \to M, U \subset B \). Galois groupoid of \( \Phi \) (or its difference equation) is denoted by \( \text{Mal}(\Phi/B) \), roughly speaking it is the algebraic pseudogroup of local holomorphic transformations of fibers of \( \pi \) generated by restrictions of \( \Phi \) to fibers. By considering all order \( k \) Taylor expansions of all elements in \( \text{Mal}(\Phi/B) \) at all theirs points of definition one gets a finite dimensional algebraic variety called \( \text{Mal}_k(\Phi/B) \). The Galois groupoid has a natural structure of pro-algebraic variety.

1.1. Confluence and specialisation. When a dynamical system depends on parameters, we wonder how the Galois groupoid depends on these parameters. For linear differential equation an answer was given by [Gol57]. A generalisation of these specialisation results including difference equation can be found by a Tannakian approach in [And01]. As a byproduct, these theorems can be used to obtained bound on the Galois group of a differential equation given as the continuous limite of a difference equation.

Let \( B \to S \) be a rational map invariant by \( \sigma \). We can choose a value \( s \in S \) and considere the restriction of the dynamical system \( \Phi_s : M_s \to M_s \) above \( \sigma_s : B_s \to B_s \). The general opinion is that the dynamical behaviour of \( \Phi_s \) for a particular value of \( s \in S \) must be simpler that the behaviour on the generic fiber. This is the specialisation theorem.

Theorem [7 page 6]. In the situation above, \( \dim \text{Mal}_k(\Phi_s/B_s) \leq \dim_S \text{Mal}_k(\Phi/B) \) with equality for general \( s \in S \).

1991 Mathematics Subject Classification. 12H05 34M55.

Key words and phrases. (eng) difference equations, continuous limit, Galois groupoid. (fr) équations aux différences, confluence, groupoide de Galois.
A property is true for a general \( s \in S \) if it is true for \( s \) out of a countable union of proper algebraic subvarieties of \( S \).

The second theorem concerns vector fields obtained as continuous limits of discrete dynamical systems. This means that \( S \) is one dimensional and near a special point \( s_0 \in S \), one can write \( \Phi_s = 1d + (s - s_0)X + o(s - s_0) \); \( 1d \) is the identity map on \( M_{s_0} \) and \( X \) is a rational vector field on \( M_{s_0} \). Again we will prove that the dynamical behaviour of \( X \) is simpler that the behaviour of \( \Phi \). This is the confluence theorem.

**Theorem** (page 5). In the situation above, \( \dim \text{Mal}_k(X/B_{s_0}) \leq \dim_S \text{Mal}_k(\Phi/B) \).

1.2. The main example. A discrete Painlevé equation is a birational self-map \( \Phi \) of \( \mathbb{C}^2 \times \mathcal{C} \) fibered above an automorphism without periodic points of the curve \( \mathcal{C} \) of the independent variable \( n \). This curve may be non compact. Formally the difference equation of invariant curves paramaterized by \( n \) is the difference equation. Following [RGH91], two properties are imposed to be called “discrete-Painlevé equation”:

1. It must have the singularities confinement property. There exists a fiberwise extension \( M \) of \( \mathcal{C} \) \( \rightarrow \mathcal{C} \) such that \( \Phi \) can be extended as a biholomorphism of \( M \).
2. It must degenerate on a differential Painlevé equation. There exists a deformation \( \hat{\Phi} \) of \( \Phi \) such that for \( \epsilon \in (\mathbb{C}^*, 0) \) the couple \((\hat{M}_\epsilon, \hat{\Phi}_\epsilon)\) is birational to \((M, \Phi)\) and at 0 one has a Taylor expansion \( \hat{\Phi}_\epsilon = 1d + \epsilon X + o(\epsilon) \) with \( X \) a vector field on \( \hat{M}_0 \) whose trajectories parameterized by open set in \( \mathcal{C}_0 \) are Painlevé transcendents. This vector field is called a continuous limit of \( \Phi \).

In [Sak01], H. Sakai achieved the classification of total spaces \( M \) of definition of discrete Painlevé equations. For a overview on difference Painlevé equations the reader may see [KNY17]. Let us describe the easiest non trivial example.

1.2.1. The discrete Painlevé 2 equation. Consider the rational dominant map:

\[
\Phi_0 : \mathbb{C}^6 \rightarrow \mathbb{C}^6,
\]

\[
\begin{bmatrix}
x \\
y \\
a \\
b \\
c \\
n 
\end{bmatrix}
\Rightarrow
\begin{bmatrix}
x \\
y \\
a \\
b \\
c \\
n + 1 
\end{bmatrix} + \frac{(a + bn)x + c}{1 - x^2}.
\]

Invariant analytic curves parameterized by \( n \) are solutions of the so-called discrete Painlevé two equation:

\[
dP_0(a, b, c) : x(n + 1) + x(n - 1) = \frac{(a + bn)x(n) + c}{1 - x(n)^2}.
\]

This equation degenerates on the second Painlevé equation. For \( \epsilon \in \mathbb{C}^* \), the change of variable \( t = \frac{2}{\epsilon} \), \( f = y/\epsilon \), \( g = (x - y)/\epsilon^2 \), \( \alpha = (a - 2)/\epsilon^4 \), \( \beta = (b - \epsilon^2)/\epsilon^4 \) and \( \gamma = c/\epsilon^3 \) can be used to get a trivial family \( \Phi_\epsilon \) of rational dominant maps above \( \mathbb{C}^* \) with a special degenerated fiber at 0. A direct computation gives the expression of \( \Phi_\epsilon \) in these new coordinates:

\[
\Phi_\epsilon : \mathbb{C}^6 \rightarrow \mathbb{C}^6,
\]

\[
\begin{bmatrix}
t \\
f \\
\alpha \\
\beta \\
\gamma 
\end{bmatrix}
\Rightarrow
\begin{bmatrix}
t \\
f \\
\alpha \\
\beta \\
\gamma 
\end{bmatrix} + \frac{1}{2f^3 + tf + \gamma} + o(\epsilon).
\]

from which one gets the confluence of the family \( \Phi_\epsilon(\alpha, \beta, \gamma, \epsilon) \) on the vector field \( X_\gamma = f_t + g_{\partial t} + (2f^3 + tf + \gamma)\frac{\partial}{\partial y} \) whose trajectories parameterized by \( t \) are solutions of the second Painlevé equation \( P_0(\gamma) : \frac{\partial^2 t}{\partial t^2} = tf + 2f^3 + \gamma \).
1.2.2. The second Painlevé equations. From [CW18], we know the Galois groupoid of $X_0$ and from [Dav] we know that that Galois groupoid of $X_0$ over $C$ is the pseudogroup of invariance of the times form $dt$ and the closed 2-form $\iota_x dt \wedge df \wedge dg$ for very general values of $\gamma$. The main theorems, Theorem 7 and Theorem 8, can be used to determine for very general values of $(a,b,c)$ the Galois groupoid of $\Phi_0(a,b,c)$ over $C(n)$:

**Theorem** [page 7].

$$\text{Mal} (\Phi_0(a,b,c)/C(n)) = \{ \varphi : (C^2, p_1) \rightarrow (C^2, p_2) \mid p_1, p_2 \in C^2, \varphi^* dx \wedge dy = dx \wedge dy \}$$

1.3. Galois groupoid and irreducibility. The notion of irreducibility of a differential equation is as old as differential equations. It is formalized by K. Nishioka [Nis88] and Umemura [Ume88, Ume90] following original ideas from Painlevé’s Stockholm Lessons [Pai73]. A discrete version of irreducibility can be found in [Nis10]. Let us recall a weaker version of the definition.

**Definition 1.** A rational second order difference equation $E : x(n + 2) = F(n, x(n), x(n + 1))$ is reducible if there exist a tower of field extension

$$\mathbb{C}(n) = K_0 \subset K_1 \ldots \subset K_N$$

such that

1. each intermediate extension $K_{i-1} \subset K_i$ is of one of the following type
   a. algebraic,
   b. generated by entries of a fundamental solution of a linear system with coefficients in $K_{i-1}$,
   c. generated by a solution of a first order non linear difference equation with coefficients in $K_{i-1}$,
2. there exists a solution $x \in K_N$ with $n, x(n), x(n + 1)$ algebraically independent in $K_N$.

From numerous papers by S. Nishioka [NN13, Nis09, Nis12], we know the irreducibility of many discrete Painlevé equation. The proofs are done by direct and very specific computation.

The aim of our work is to provide a new proof of irreducibility of most of the discrete Painlevé equations based on the computation of theirs Galois groupoids using the confluence of such discrete equations on differential Painlevé equations. Such a proof should prove irreducibility of any discrete dynamical system which admit as continuous limit second order equation with a big enough Galois groupoid (such as 1.2.2). This seems to be done using theorems of this article together with discrete analog of results from [Cas09]. This will be done in future work.

2. Fibered dynamical systems and transversal Galois groupoid

When a dynamical system $\Phi : M \rightarrow M$ comes from a difference equation, it preserves the foliation by fibers of the map $M \rightarrow B$ given by the independent coordinates. Moreover in the case with parameters, $\Phi$ preserves the fibers of the map given by the parameters. Let $M$ be the phase space, $B$ the space of the independent variable and parameters and $S$ the parameters space. We have a commutative diagram

$$\begin{array}{ccc}
M & \xrightarrow{\Phi} & M \\
\downarrow & & \downarrow \\
B & \xrightarrow{\sigma} & B \\
\downarrow & & \downarrow \\
S & = & S
\end{array}$$

where $\sigma$ is the map corresponding to the operator involved in the difference equation.

2.1. The fibered frames bundle. Let $q$ be the dimension of fibers of $M$ over $B$. The space of frames on fibers of $M \rightarrow B$ is

$$R(M/B) = \{ r : (C^q, 0) \rightarrow M_b \mid b \in B \text{ and } \det(Jr) \neq 0 \}$$

where $Jr$ is the Jacobian matrix of $r$ at $0$. Its coordinates ring of $R(M/B)$ is

$$(\text{Sym}(C[M] \otimes C[\partial_1, \ldots, \partial_q])/\mathcal{L})[1/jac]$$

where

- the tensor product is a tensor product of $\mathbb{C}$-vector spaces;
• $Sym(V)$ is the $\mathbb{C}$-algebra generated by the vector space $V$;
• $Sym(C[M] \otimes C[\partial_1, \ldots, \partial_q])$ has a structure of $C[\partial_1, \ldots, \partial_q]$-differential algebra via the right composition of differential operators;
• the Leibniz ideal $\mathcal{L}$ is the $C[\partial_1, \ldots, \partial_q]$-ideal generated by $fg \otimes 1 - (f \otimes 1)(g \otimes 1)$ for all $(f, g) \in C[M]^2$, $h \otimes \partial_b$, for $b \in C[B]$ and $1 \leq i \leq q$ and $1 \otimes 1 - 1$;
• the quotient is then localized by $jac$ the sheaf of ideals (not differential !) generated by $det(x_i \otimes \partial_j)$ for a transcendental basis $(x_1, \ldots, x_q)$ of $C(M)$ over $C(B)$ on Zariski open subset of $M$ where such a basis is defined.

Local coordinates $(b_1, \ldots, b_p, x_1, \ldots, x_q)$ on $M$ such that the projection on $B$ is the projection on $b$’s coordinates, induce local coordinates on $R(M/B)$ via the Taylor expansion of maps $r$ at $0$

$$r(e_1, \ldots, e_q) = \left( b^0_1, \ldots, b^0_p, \sum r^0_{i\alpha} \frac{\epsilon^\alpha}{\alpha!}, \ldots, \sum r^q_{i\alpha} \frac{\epsilon^\alpha}{\alpha!} \right).$$

One denotes $x_1^\alpha : R(M/B) \rightarrow \mathbb{C}$ the function defined by $x^\alpha_1(r) = r^\alpha_1$. This function is the element $x_1 \otimes \alpha$ in $C[R(M/B)]$.

1. The action of $\partial_j : C[R(M/B)] \rightarrow C[R(M/B)]$ can be written in local coordinates and gives the total derivative operator $\sum x^{\alpha+1}_i \frac{\partial}{\partial x^\alpha_i}$ where $i$ is the multiindex whose only non zero entry is the $j^{th}$ and its values is 1.
2. The vector space $C[\partial_1, \ldots, \partial_q]$ is filtered by $C[\partial_1, \ldots, \partial_q]^{\leq k}$ the spaces of operators of order less than $k$. This gives a filtration of $C[R(M/B)]$ by $C$-algebras of finite type.
3. These algebras are coordinate ring of the space of $k$-jet of frames $R_k(M/B) = \{ j_k r \mid r \in R(M/B) \}$.
4. The action of $\partial_1, \ldots, \partial_q$ have degree +1 with respect to the filtration.

2.2. Prolongation of dominant morphism and vector fields. Morphisms (resp. derivations) from $C[M]$ to $C[M]$ with a non zero Jacobian determinant and preserving $C[B]$ act on $C[R(M/B)]$ as morphisms (resp. derivations).

If the map $\Phi$ is regular and induces $\Phi^* : C[M] \rightarrow C[M]$. Its action of the frame bundle is defined by $Sym(\Phi \otimes 1)$ on $Sym(C[M] \otimes C[\partial_1, \ldots, \partial_q])$, it can be easily checked that the Leibniz ideal is preserved. The induced map $C[R(M/B)] \rightarrow C[R(M/B)]$ corresponds to an endomorphism of $R(M/B)$ denoted by $R\Phi$ and is called the prolongation of the morphism. The prolongation of a derivation of $C[M]$ preserving $C[B]$ is a derivation of $C[R(M/B)]$ defined in the same way.

If the map $\Phi$ is rational and dominant with domain of definition $M^\circ$, its prolongation on $R(M^2/B)$ is a rational dominant map on $R(M/B)$. Rational vector fields on $M$ can be prolonged on $R(M/B)$ in a similar way.

Prolongations of morphisms and derivations of $C[M]$ on $C[R(M/B)]$ have degree 0 with respect to the filtration defined above. Prolongations commute with the differential structure. When $X$ is a rational vector field on $M$ preserving $M \rightarrow B$, its prolongation $RX$ on $R(M/B)$ can be computed with an explicit formula :

Let $X = \sum c_i(b) \frac{\partial}{\partial b_i} + \sum a_i(x,b) \frac{\partial}{\partial x^\alpha_i}$ be a vector field preserving $M \rightarrow B$ in local coordinates. One gets $RX = \sum c_i(b) \frac{\partial}{\partial b_i} + \sum a_i(x,b) \frac{\partial}{\partial x^\alpha_i} \partial^{\alpha_i} a_i$.

2.3. The space $R(M/B)$ is a principal bundle over $M$. Let us describe this structure here. The pro-algebraic group

$$\Gamma = \{ \gamma : (\mathbb{C}^q, 0) \rightarrow (\mathbb{C}^q, 0); \text{formal invertible} \}$$

is the projective limit of groups $\Gamma_k = \{ jk \gamma \mid \gamma \in \Gamma \}$. It acts on $R(M/B)$ by composition and $R(M/B) \times \Gamma \rightarrow R(M/B) \times R(M/B)$ sending $(r, \gamma)$ to $(r, r \circ \gamma)$ is an isomorphism. The action of $\gamma \in \Gamma$ on $R(M/B)$ is denoted by $S_\gamma : R(M/B) \rightarrow R(M/B)$ as it acts as a change of source coordinate of frames. At the coordinate ring level, this action is given by the action of formal change of coordinate on $C[\partial_1, \ldots, \partial_q]$ followed by the evaluation at 0 in order to get operators with constant coefficients. This action has degree 0 with respect to the filtration induced by the order of differential operators meaning that for any $k$, the bundle of order $k$ frames $R_k M$ is a principal bundle over $M$ for the group $\Gamma_k = \{ jk \gamma \mid \gamma \in \Gamma \}$. 

Galois Groupoid and Confluence of Difference Equations
2.4. Compatibility of the differential and principal structures. Let \( \epsilon_1, \ldots, \epsilon_q \) be coordinates on \((\mathbb{C}^q, 0)\) such that \( \partial_\epsilon = \frac{\partial}{\partial \epsilon} \). The Lie algebra of \( \Gamma \) is the Lie algebra of formal vector fields vanishing at 0 : \( \mathfrak{X}^0(\mathbb{C}^q, 0) \). The infinitesimal action of \( v = \sum a_i(\epsilon) \partial_\epsilon \in \mathfrak{X}(\mathbb{C}^q, 0) \), the Lie algebra of formal vector fields on \( R(M/B) \) is \( f \circ P \mapsto f \circ (P \circ v)|_{c=0} \). When \( v \) belongs to \( \bigoplus \mathcal{O}(\partial) \), this action is the differential structure ; when \( v \) belongs to \( \mathfrak{X}^0(\mathbb{C}^q, 0) \), it is the action induced by the action of the group \( \Gamma \).

2.5. The fibers automorphism groupoid. A groupoid is naturally associated to any principal bundle. In the case of \( R(M/B) \) one can give three definitions of this groupoid.

1. The groupoid \( \text{Aut}(M/B) \) is the groupoid of formal invertible maps:
   \[ \{ \hat{\gamma} : (M_b, p_1) \to (M_{b'}, p_2) \mid (b, b') \in B \times B, p_1 \in M_b, p_2 \in M_{b'} \} \]

2. The map
   \[ R(M/B) \times R(M/B) \to \text{Aut}(M/B) \]
   \[ (r, s) \mapsto r \circ s^{s^{-1}} \]
   realized the quotient by the diagonal action of \( \Gamma \).

3. The groupoid of \( \Gamma \)-equivariant maps between fibers of \( \pi : R(M/B) \to M \) is \( \text{Aut}(M/B) \).

The second definition is adapted to prove that \( \text{Aut}(M/B) \) is pro-algebraic groupoid.

2.6. Galois groupoids. It is a proper generalisation of the Galois group of linear differential or difference equation. It is a quotient of the Galois groupoid defined in [Mal10] for foliations and in [Gra11, Cas06] for rational dominant maps.

2.6.1. Galois groupoid of a rational vector field. The Galois groupoid for vector fields where already studied in [Dav]. We recall the definition in the fibered situation. The proof are immediate from definition then \( R(M/B) \).

A rational functions \( H \in \mathbb{C}(R(M/B)) \) such that \( RX \cdot H = 0 \) is a differential invariant of \( X \). Let \( \text{Inv}(X) \subset \mathbb{C}(R(M/B)) \) be the subfield of differential invariants of \( X \). Let \( W \) be a model for \( \text{Inv}(X) \)

\[ \text{Def 2.} \text{ The transversal Galois groupoid is } \text{Mal}(X/B) = R(M/B) \times R(M/B) \subset \text{Aut}(M/B) \]

To defined properly this fiber product one needs to restrict \( \pi : (R(M/B))^o \to W \) on its domain of definition then \((R(M/B) \times R(M/B))^o \) is defined to be the Zariski closure of \((R(M/B))^o \times R(M/B))^o \) in \( R(M/B) \times R(M/B) \).

When \( B = \{ \ast \} \), D. Davy [Dav] proved that this definition is equivalent to Malgrange’s original definition. In particular Malgrange shows in [Mal10] that there exists a Zariski open subset \( M^o \) of \( M \) such that the restriction of \( \text{Mal}(X) \) to \( \text{Aut}(M^o) \) is a subgroupoid.

2.6.2. Galois groupoid of a rational dominant map. A rational functions \( H \in \mathbb{C}(R(M/B)) \) such that \( H \circ R\Phi = H \) is a (fibered) differential invariant of \( \Phi \). Let \( \text{Inv}(\Phi) \subset \mathbb{C}(R(M/B)) \) be the subfield of differential invariants of \( \Phi \).

Let \( W \) be a model for \( \text{Inv} \) and \( \pi : R(M/B) \to W \) be the dominant map induced by the inclusion \( \text{Inv}(X) \subset \mathbb{C}(R(M/B)) \).

\[ \text{Def 3.} \text{ The (fibered) Galois groupoid is } \text{Mal}(\Phi/B) = R(M/B) \times R(M/B) \subset \text{Aut}(M/B) \]

Here again, to defined properly this fiber product one needs to restrict \( \pi : (R(M/S))^o \to W \) on its domain of definition then \((R(M/B) \times R(M/B))^o \) is defined to be the Zariski closure of \((R(M/B))^o \times R(M/B))^o \) in \( R(M/B) \times R(M/B) \).

The following lemmas are important in the proof of the specialisation theorem.

\[ \text{Lem 4.} \text{ Let } O \subset R(M/B)^o \text{ be a Zariski open subset then } O \times O = R(M/B)^o \times R(M/B)^o. \]

\[ \text{Lem 5.} \text{ Galois groupoid of } \Phi \text{ is the Zariski closure of the set of Taylor expansions of iterates of } \Phi. \]
The dimension of \( \text{Mal}(\Phi/B) \) is the dimension of \( M \) plus the dimension of the Zariski closure of a general orbit of \( R_k(\Phi) \) in \( R_k(M/B) \). One has to prove that the dimension of the Zariski closure of a particular orbit is smaller that the general one. The proof is done in [AC08]. It can be adapted from [Bon06] where this inequality is proved for leaves of algebraic foliations.

For \( jkr \in R_k(M/B) \), \( \text{V}(jkr) \) is the Zariski closure of the orbit of \( jkr \). We will compare Hilbert polynomial of these subvarieties and deduce the wanted inequalities of dimensions.

The ideal of \( \text{V}(jkr) \) is \( I(jkr) = \{ f \in \mathbb{C}[R_k(M/B)] | \forall n \in \mathbb{N} \ jkr(r) \in \{ f \circ \Phi^n = 0 \} \} \) and the subvector space of equation of degree less than or equal to \( d \) is also described by these linear equations in \( f \) depending on \( r \). Let \( h_{jkr}(d) \) be the dimension of this space. There exists a Zariski open subset \( O \subset R_k(M/B) \) and an integer \( h_k \) such that for any \( r \), \( h_{jkr}(d) \geq h_k \) with equality for \( jkr \in O \).

This implies that the Hilbert polynomial of \( \text{V}(jkr) \) is constant for \( jkr \) general in \( R_k(M/B) \), and that for other frames, it is smaller. The dimension of a subvariety is the degree of its Hilbert polynomial. The theorem is proved.

3. The confluence theorem. In this section, we will assume the parameter space to be 1-dimensional with coordinate \( s \). This theorem compares Galois groupoids of \( \Phi \) with Galois groupoid of \( X \) a vector field on \( M_{s_0} \) such that \( \Phi_0 = Id + (s - s_0)X + o(s - s_0) \)

**Theorem 8.** For all \( k \in \mathbb{N} \), \( \dim \text{Mal}_k(X/B_{s_0}) \leq \dim_S \text{Mal}_k(\Phi/B) \)
Proof. – First, the restrictions of differential invariants of \( \Phi \) at \( s = s_0 \) give differential invariants of \( X \). By expansion around \( s_0 \), \( R\Phi_s = Id + (s - s_0)RX + o(s - s_0) \) and \( H = H^0 + o(s - s_0) \) then \( H \circ R\Phi_s = H \) implies \( RX \cdot H^0 = 0 \). This means that the fiber of \( Mal_k(\Phi/B) \) at \( s_0 \) contains \( Mal_k(X/B) \) or equivalently \( Inv(R_k\Phi)_{s_0} \) contains \( Inv(R_kX) \).

To prove the inequality one has to prove that \( dim Mal_k(\Phi/B)_{s_0} \leq dim_s Mal_k(\Phi/B) \). As the codimension of these varieties are given by the transcendence degree of theirs fields of differential invariant, we will compare \( Inv(R_k\Phi)_{s_0} \) and \( Inv(R_k\Phi) \).

Let \( H_1, \ldots, H_p \) be a transcendence basis of \( Inv(R_k\Phi) \) over \( \mathbb{C}(s) \). Because \( s \) is a differential invariant, one can assume that the restriction of the basis to \( s = s_0 \) are well defined rational functions \( H_1^0, \ldots, H_p^0 \) and the vanishing order \( \ell \) of \( dH_1 \wedge \ldots \wedge dH_p \) at \( s = s_0 \) is minimal. If \( \ell = 0 \), these restrictions are functionally independent, the theorem is proved. If not, let \( P(H_1^0, \ldots, H_p^0) \) be the minimal polynomial of \( H_p^0 \) over \( \mathbb{C}[H_1^0, \ldots, H_p^0] \). The invariant \( P(H_1, \ldots, H_p) \) can be written as \((s - s_0)P \) with \( P \) a function of \( s, H_1, \ldots, H_p \). Up to some factorisation by \( s - s_0 \) one can assume that there exist a index \( i \) such that \( (\partial_s P)^0 \) is well defined and not zero. One has, up to some sign and mod \( ds \),

\[
d(P(H_1, \ldots, H_p)) \wedge dH_1 \wedge \ldots \wedge dH_p = \partial_i PdH_1 \wedge \ldots \wedge dH_p = (s - s_0)dF \wedge dH_1 \wedge \ldots \wedge dH_p
\]

This contradicts the minimality of \( \ell \). \( \square \)

3.3. Corollaries about Galois groupoids of discrete Painlevé equations. A discrete Painlevé equation is a birational map \( \Phi \) of \( \mathbb{C}^2 \times \mathbb{C} \) fibered above a automorphism without periodical points of the curve of the independent variable \( n \). This curve may be non compact. Formally the equation of invariant curves paramatrized by \( n \) is the difference equation. Two properties are imposed to be called “discrete-Painlevé equation”:

(1) It must have the singularity confinement property. There exists a fibers compactification \( M \) of \( \mathbb{C}^2 \times \mathbb{C} \rightarrow \mathbb{C} \) such that \( \Phi \) can be extended as a biholomorphism of \( M \).

(2) It must degenerate on a differential Painlevé equation. There exists a deformation \( \tilde{M} \) of \( M \) above \( \mathbb{C} \) and a deformation \( \tilde{\Phi} \) of \( \Phi \) such that for \( \epsilon \in \mathbb{C}^*, (\tilde{M}, \tilde{\Phi}) \) is birational to \( (M, \Phi) \) and at 0 one has the Taylor expansion \( \tilde{\Phi}_0 = Id + \epsilon X + o(\epsilon) \) with \( X \) a vector field on \( \tilde{M}_0 \) whose trajectories parameterized by open set in \( \mathbb{C} \) are Painlevé transcendentals. This vector field is called a continuous limit of \( \Phi \).

The classification of the phase spaces of these equations can be found in \cite{Sak01}. The equations themselves can be found in \cite{KNTY17}. The spaces are classified by families indexes by affine Weyl groups \( W \), each family depends on finite number of parameters \( a \). Then Painlevé equations are denoted by \( dpW(a), dpW^0(a), dpW^{0i}(a), qP(a) \ldots \). In this article any of these equations will be denoted by \( dpW(a) \).

In Sakai’s classification \cite{Sak01}, it is proved that there exists an invariant relative 2-form \( \omega \in \Omega^2_{M/\mathbb{C}} \). In the framework of this article this means that we have an inclusion:

\[
Mal(dpW(a)/\mathbb{C}) \subset \{ \varphi : (M_n, p) \rightarrow (M_{n'}, q) | (n, n') \in \mathbb{C}^2, \varphi^* \omega = \omega \}.
\]

This inclusion, the second property above and Cartan generic local classification of algebraic pseudogroups \cite{Car08} enable us to compute Galois groupoid of discrete Painlevé equations.

Theorem 9. For any affine Weyl group \( W \) and for general values of parameters \( a \)

\[
Mal(dpW(a)/\mathbb{C}) = \{ \varphi : (M_n, p) \rightarrow (M_{n'}, q) | (n, n') \in \mathbb{C}^2, \varphi^* \omega = \omega \}.
\]

Proof. – First one will determined the codimension 2 subvariety given for \( n \in \mathbb{C} \) by \( M_{n,n} = Mal(dpW(a)/\mathbb{C}) \cap \{ \varphi : (M_n, p) \rightarrow (M_n, q) \} \). It is a subgroupoid of \( Inv(\omega_n) = \{ \varphi : (M_n, p) \rightarrow (M_n, q) | \varphi^* \omega = \omega \} \). The restriction of these pseudogroups on a fiber \( M_n \) give algebraic pseudogroups on two dimensional manifolds. Such objects have been classified by Elio Cartan \cite{Car08} up to analytic change of coordinates near a generic point. From the specialisation theorem we know that \( dim(M_{n,n}) \) the algebraic variety of jet of order \( k \) of element of \( M_{n,n} \) has a quadratic growth in \( k \). From Cartan results we know that there is only one quadratic growth subgroupoid of \( Inv(\omega_n) \) : it is \( Inv(\omega_n) \) itself.

Now the two groupoids dominate \( \mathbb{C} \times \mathbb{C} \) and have same fibers above the diagonal, they are equals. \( \square \)
