Polychlorinated biphenyls (PCBs) are ubiquitous environmental contaminants routinely found in human and animal tissues. Developmental exposure to PCBs is associated with neuropsychologic deficits, which may be related to effects on thyroid hormone (TH) signaling in the developing brain. However, PCBs may interfere with TH signaling solely by reducing circulating levels of TH, or they may exert direct effects on TH receptors (TRs). Therefore, we tested whether maternal exposure to a commercial PCB mixture, Aroclor 1254 (A1254), exerts effects in the fetal brain by one or both of these mechanisms. Dams were dosed daily with 0, 1, or 4 mg/kg A1254 from gestational day 6 (GD6) until they were sacrificed on GD16. A1254 significantly reduced circulating levels of triiodothyronine (T3) and thyroxine (T4) in pregnant rats but increased the expression of several TH-responsive genes in the fetal cortex, including neuroendocrine-specific protein A (NSP-A), RC3/neurogranin, and Oct-1. These findings are consistent with a direct action of PCBs on TRs. However, we did not identify parent PCB congeners or metabolites that bound to rat TRs isolated from hepatic nuclei. These findings indicate that PCBs can interfere with TH signaling in the fetal brain by direct actions on the fetus rather than by producing maternal hypothyroidism. Key words: brain development, endocrine disruption, NSP-A, NSP-C, Oct-1, PCBs, RC3/neurogranin, thyroid, thyroid hormone. Environ Health Perspect 112:516–523 (2004). doi:10.1289/ehp.6672 available via http://dx.doi.org/ [Online 22 December 2003]

Polychlorinated biphenyls (PCBs) are industrial chemicals consisting of paired phenyl rings with various degrees of chlorination (Chana et al. 2002). Although the production of PCBs was banned in the mid-1970s, these contaminants are routinely detected in the environment (Breivik et al. 2002). The chemical stability and lipophilicity of these compounds allow them to bioaccumulate through the food chain, and they are found in high concentrations in samples of human tissues (Fisher 1999). A number of epidemiologic studies have indicated that children developmentally exposed to PCBs suffer from neuropsychologic deficits such as a lower full-scale IQ, reduced visual recognition memory, attention deficits, and motor deficits (Ayotte et al. 2003; Huisman et al. 1995; Jackson et al. 1997; Korrick and Altshul 1998; Osisi et al. 1999; Walkowiak et al. 2001). Both postnatal and prenatal exposure to PCBs contributes to these deficits, although some authors argue that prenatal exposure is more strongly associated with neuropsychologic deficits, which indicates that fetal neurodevelopment is particularly vulnerable to PCB exposure (Jacobson and Jacobson 2002).

The specific neuropsychologic domains affected by developmental exposure to PCBs overlap with those affected by maternal thyroid hormone (TH) insufficiency, including lower IQ, visual memory deficits, and motor function and attention deficits (Haddow et al. 1999; Morreale de Escobar et al. 2000; Pop et al. 1999). Therefore, several investigators have speculated that PCBs may affect brain development by interfering with TH signaling (McKinney and Waller 1998; Porterfield 2000; Porterfield and Hendry 1998). This hypothesis is supported by the observation that the concentrations of PCBs, or of specific PCB congeners, in maternal and cord blood are associated with lower TH levels in both the mother and infant (Koopman-Esseboom et al. 1994; Schantz et al. 2003). Although several epidemiologic studies have failed to identify an association between TH and PCB body burden (Hagmar et al. 2001; Longnecker et al. 2000; Matsuura and Konishi 1990; Sala et al. 2001; Steuerwald et al. 2000), experimental studies consistently find that PCB exposure decreases circulating levels of thyroxine (T4) in rats (Bastomsky 1974; Bastomsky et al. 1976; Brouwer et al. 1998). Therefore, it is possible that PCB body burden is negatively associated with serum TH levels in humans but that the variability inherent in human populations makes this association difficult to reveal.

Despite the finding that PCBs uniformly reduce circulating levels of TH in experimental animals, PCBs do not exert effects in experimental animals that are fully consistent with experimentally produced hypothyroidism using goitrogens such as propylthiouracil (PTU). For example, developmental exposure to PCBs in experimental animals induces hearing loss (Crofton et al. 2000a, 2000b; Goldey et al. 1995a, 1995b), a reduction in choline acetyltransferase in the cerebral cortex (Juarez de Ku et al. 1994), and an increase in testicular growth, all consistent to some degree with effects produced by PTU. Moreover, T4 replacement can at least partially ameliorate these effects (Goldey and Crofton 1998; Juarez de Ku et al. 1994), indicating that PCBs can influence brain development in part by causing a reduction in serum TH. However, developmental hypothyroidism induced by PTU exposure causes a significant increase in serum concentrations of thyroid-stimulating hormone (thyrotropin; TSH) (Connors and Hedge 1981), reduced body and brain weight as well as reduced brain size of rat pups (Schwarz 1983), and a delay in eye opening and tooth eruption (Varma et al. 1978). In contrast, PCB exposure at doses that lower serum TH does not always produce these effects (Goldey et al. 1995a; Hood and Klaassen 2000; Kolaja and Klaassen 1998; Zoeller et al. 2000). Therefore, there is a discrepancy between the ability of PCBs to reduce circulating levels of TH and their ability to produce symptoms of hypothyroidism.

Some authors have proposed that this discrepancy may be attributable to PCBs acting as imperfect agonists/antagonists on TH receptors (TRs) (McKinney and Waller 1994). TRs are members of the steroid/thyroid superfamily of ligand-dependent transcription factors (Mangelsdorf et al. 1995). They are encoded by two genes, designated α and β c-erbA (encoding TRα and TRβ) (Sap et al. 1986; Weinberger et al. 1986). Both genes are alternatively spliced in a tissue-specific manner, and the specific receptors are expressed in a tissue-specific manner in the developing brain (Cotrell et al. 2002).
producing a variety of functional TR isoforms (TRβ1, TRβ2, TRβ3, TRα1) (Flamant and Samarut 2003). TRα1 and TRβ1 are the predominant isoforms that are expressed throughout brain development (Bradley et al. 1989, 1992, 1994) and in other tissues such as liver, intestine, and heart (Brent 2000). However, only one report has addressed this proposal directly (Check et al. 1999), finding that two hydroxylated PCB congeners (4′-OH-PCB-14 and 4′-OH-PCB-106) exhibit a relatively low affinity for human TRβ1 (K_i = 32 µM).

Considering these findings, the present studies were initiated for two reasons. First, we tested the hypothesis that maternal PCB exposure could affect the fetal cerebral cortex by reducing the availability of TH to the fetus. We previously showed that low maternal TH, produced experimentally by goitrogen treatment, can alter gene expression in the fetal cortex before the onset of fetal thyroid function (Dowling et al. 2000, 2001; Dowling and Zoeller 2000). Therefore, if PCBs reduce circulating levels of maternal TH, then gene expression in the fetal cortex should respond in a manner consistent with hypothyroidism. Second, we tested the hypothesis that individual PCBs or their metabolites could bind to the TR. To test this, we used rat hepatic nuclei as a source of both TRα1 and TRβ1.

Materials and Methods

Chemicals. Acrolor 1254 (A1254; lot no. A8110048) and individual PCB congeners (PCBs 77, 105, 118, 126, 138, and 153) were purchased from AccuStandard, Inc. (New Haven, CT). Methylsulfonyl-PCBs (MeSO_2-PCBs) were synthesized according to Harachuga et al. (1987). The purity of these compounds was > 99% as determined by gas chromatography. The hydroxylated PCB congeners (4′-OH-PCB-14 and 4′-OH-PCB-106) were hydroxylated in plastic cages with food and water provided continuously and were maintained on a 12:12-hr light cycle (0600 hr to 1800 hr). All dams were provided daily with a Kebler Golden Vanilla Wafer (The Kellog Company, Battle Creek, MI) dosed with A1254 on GD6 through GD16. The rats were weighed and measured for doses of 0, 1, and 4 mg/kg (n = 6/group); details of this method have been described previously (Zoeller et al. 2000).

On GD16, dams were euthanized with carbon dioxide, and trunk blood was collected for measurement of serum total T_3 by radioimmunoassay (RIA). The pregnant uterine horns were removed and immediately placed on ice. Fetuses were dissected from the uterus, frozen on pulverized dry ice, and stored at −80°C until cryosectioned.

In situ hybridization. The NSP-A cDNA and NSP-C oligonucleotide probes have been described previously (Dowling et al. 2001), and the RC3/neurogranin construct (pPRC/CMV-RC3) was kindly provided by J. Bernal (Madrid, Spain; Iniguez et al. 1996). A fragment of rat Oct-1 transcript was cloned by standard polymerase chain reaction methods using primers designed to amplify a 1.2-kb region of the gene (2461–1481, GenBank accession number U17013; National Center for Biotechnology Information, Bethesda, MD). The forward (5′-GCACCAACCACCA-CAACTTGG-3′) and reverse (5′-GGTGCCCATCAGGCCTGGATT-3′) primers were synthesized by Custom Primers (Invitrogen, Inc., Carlsbad, CA). The 1.2-kb fragment was then ligated into the pCRRI TOPO vector using the Topo TA cloning kit according to the manufacturer’s instructions (Invitrogen), and its authenticity was confirmed by sequence analysis.

Probes were generated in vitro by linearization with the restriction enzymes and transcription with the RNA polymerases specified for each construct (Table 1). Transcription reactions and in situ hybridization procedures have been described previously (Zoeller et al. 1997). After in situ hybridization, slides were arranged in X-ray cassettes and exposed to BioMax film (Eastman Kodak Co., Rochester, NY); the duration of exposure was dependent on the specific activity of the probe and the abundance of the target mRNA (2 weeks for the RC3/neurogranin cRNA probe, 1 week for the Oct-1 and NSP-A cRNA probes, and 2 days for the NSP-C oligonucleotide probe). To verify that the films were not overexposed, [13C]-labeled standards (American Radiolabeled Chemicals Inc., St. Louis, MO) were simultaneously exposed to all films. The hybridization signal was analyzed as follows. First, a 5× magnified image was captured using a Scion AG-5 capture board interfaced with the public domain software NIH-Image 1.61/ppc (W. Rasband, National Institute of Mental Health, Bethesda, MD) run on a Macintosh G4 computer (Apple Computer Inc., Cupertino, CA). The optical system consisted of a Dage-MTI72 series video camera equipped with a Nikon macro lens mounted onto a bellows system over a light box. Measurements of relative mRNA levels were taken as the area of the signal over the cortex of GD16 fetal brains multiplied by the relative density of the film (Figure 1). The resulting values were averaged.

![Figure 1](https://example.com/image1.png)

**Figure 1.** Film autoradiographic image of NSP-A expression in the GD16 fetal brain illustrating the region of the cortex in which gene expression was measured. Fetal brain tissue was collected from the cortex by taking 12-μm horizontal sections. The top of the image is rostral, the lower portion of the image is caudal, and the fourth ventricle is labeled for orientation (V4). Using imaging software, the signal within the boxed region was delineated, and the area and density of this region of interest were then measured for each of eight sections taken from a single brain. Inset: Pseudocolor (signal intensity: red > yellow > blue > black) illustrates the mRNA expression pattern specific to each TH-responsive gene. Bar = 1.0 mm.

across eight sections for each fetus, with one fetus per litter and six litters per treatment group.

**Radioimmunoassay.** Total T₄ was measured in 5 µL of rat serum using a barbital buffer system. Briefly, each assay tube contained 100 µL barbital buffer (0.11 M barbital, pH 8.6; 0.1% wt/vol 8-anilino-1-naphthalenesulfonic acid ammonium salt; 15% bovine γ-globulin Cohn fraction II; 0.1% gelatin), 100 µL anti-T₄ (rabbit, diluted to provide a final concentration of 1:30,000; Sigma, St. Louis, MO), and 100 µL 125I-labeled T₄ (Perkin-Elmer/NEN; Boston, MA). Standards were prepared from T₄ (Sigma) measured using a Cahn electrobealance; standards were run in triplicate, whereas samples were run in duplicate. Standards were calibrated to measure serum T₄ levels from 0.4 µg/dL to 25.6 µg/dL. Tubes were incubated at 37°C for 30 min and then chilled on ice for 30 min. Bound counts were precipitated by adding 300 µL ice-cold polyethylene glycol 8000 (20% wt/wt; Sigma). Tubes were centrifuged at 1800 × g for 20 min at 4°C; the supernatant was then aspirated and the pellet counted in a gamma counter (Packard Cobra II; Global Medical Instrumentation, Inc., Albertville, MN). The assay was run at 40–50% binding; nonspecific binding was generally < 8%. The assay was validated for rat serum by demonstrating parallelism between the standard curve and a dilution series of rat serum. The two slopes did not vary significantly as evaluated by t-test for two slopes (data not shown). The variability within the assay was determined by running 10 replicates of three different standards that represent a low, medium, and high value on the standard curve. The coefficients of variance were 0.9% for 0 ng/mL; 4.7% for 3.2 µg/dL; and 3.8% for 25.6 µg/dL. All experimental samples were evaluated in a single assay.

Total triiodothyronine (T₃) was measured according to the manufacturer’s instructions using a T₃ RIA kit (ICN Diagnostics, Costa Mesa, CA). This assay was performed at 49% binding with detection limits of 50–800 ng/dL. All samples were evaluated in a single assay.

**Isolation of hepatic nuclei.** Adult male Sprague-Dawley rats were euthanized with carbon dioxide and perfused with ice-cold saline through the aorta until the liver was cleared of blood. Twenty grams of liver was then washed in 3 mM MgCl₂, 0.14 M NaCl, minced, and homogenized in 3 mM MgCl₂, 1 mM diethioletrio (DTT), and 0.32 M sucrose using a motor-driven Teflon mortar and glass pestle. The homogenate was centrifuged at 600 × g for 10 min, and the crude nuclear pellet was resuspended in 3 mM MgCl₂, 1 mM DTT, and 1.8 M sucrose. After centrifugation at 53,000 × g for 45 min, the nuclei were resuspended in binding buffer (3 mM MgCl₂; 1 mM DTT; 20 mM Tris HCl, pH 7.6; 0.32 M sucrose; and 0.3% bovine serum albumin) and stored at −80°C.

**TH binding assay.** For saturation analysis, nuclear isolates frozen in binding buffer were thawed on ice, and triplicate aliquots (~0.1 g of the original liver) were incubated with increasing concentrations of 125I-T₃ (1 × 10⁻¹⁰ to 8 × 10⁻⁸ M; 3,300 µCi/µg; NEN, Boston, MA) for 30 min at 37°C. Nonspecific binding was determined at each concentration of 125I-T₃ (and each competitor concentration) by performing the assay as described in a parallel set of tubes that included the addition of 10,000-fold excess cold T₃ (final concentration 1 × 10⁻⁶ M). The reaction was terminated by placing samples on ice and by adding binding buffer/1% Triton X-100. Samples were centrifuged at 13,000 × g for 10 min, the supernatant was discarded, and the nuclear pellet was washed in 1 mL binding buffer. The bottom of the microfuge tube

**Figure 2.** Effect of A1254 treatment on serum concentrations of total T₄ (A) and total T₃ (B) in dams at the time they were sacrificed on GD16. Bars represent mean ± SEM; number of animals in each group is shown within each bar. See Materials and Methods for treatment details.

**Figure 3.** Effect of A1254 treatment on the levels and patterns of NSP-A, Oct-1, RC3/neurogranin, and NSP-C mRNA expression in the GD16 fetal cortex. (A) Representative pseudocolor autoradiograms obtained after in situ hybridization (pseudocolor signal intensity: red > yellow > blue > black). (B) Bar graphs showing the relative abundance of mRNA expression as reflected by the mean ± SEM film density (Oct-1 and NSP-C), area (NSP-A), or integrated density (RC3) and are presented as percent control for the purpose of illustration. Abbreviations: CX, cortex; V, lateral ventricle; VZ, ventricular zone. Measurements were taken from the CZ for NSP-A and revealed that the relative area of mRNA expression was significantly elevated in the 1 mg/kg and 4 mg/kg treatment groups. The pattern of Oct-1 expression was not specific to the VZ, and when density measurements were normalized with respect to area (integrated density), an increase in the level of mRNA expression was detected in the 4 mg/kg A1254 treatment group. All CX measurements revealed that NSP-C mRNA levels did not differ among treatment groups. Bar = 50 µm.

*p < 0.05; **p < 0.01 (significantly different from control group using Bonferroni’s t-test after one-way ANOVA).
containing the pellet was cut off and placed in a 14 × 70 mm test tube, which was counted in a gamma counter (Packard Cobra II). For competitive binding assays, isolated nuclei were incubated with a final concentration of 1 × 10⁻¹⁰ M ¹²⁵I-T₃ and increasing concentrations of competitors (TR agonists: T₃, T₄, Triac (triiodothyroacetic acid), and Tetrac (tetraiodothyroacetic acid, 1 × 10⁻¹² M to 1 × 10⁻⁹ M; PCBs, 1 × 10⁻⁹ M to 1 × 10⁻³ M). For noncompetitive binding assays, isolated nuclei were incubated with 1 × 10⁻¹⁰ M ¹²⁵I-T₃ and increasing concentrations (1 × 10⁻¹² M to 1 × 10⁻⁹ M) of T₄ alone or increasing concentrations (1 × 10⁻¹² M to 1 × 10⁻⁶ M) of T₃ alone or increasing concentrations (1 × 10⁻¹² M to 1 × 10⁻⁶ M) of 125I-T₃.

**Results**

**Dams.** Exposure to A1254 significantly reduced circulating levels of total T₄ and total T₃ in dams (T₄: F(2,15) = 11.031, p = 0.0011; T₃: F(2,14) = 5.772, p = 0.0142; Figure 2). Post hoc analysis using Bonferroni's t-test revealed that dams treated daily with 4 mg/kg A1254 exhibited significantly lower levels of T₄ levels that were significantly lower than those of control animals (Figure 2A). There was a trend in animals treated with 1 mg/kg A1254 to exhibit lower circulating levels of T₄, but this did not reach statistical significance (Figure 2A). Moreover, animals treated with either 1 or 4 mg/kg A1254 exhibited significantly lower levels of circulating T₃ compared with control animals (Figure 2B).

**Fetal brains.** Quantitative analysis of film autoradiograms after in situ hybridization revealed that PCB exposure selectively affected TH-responsive genes in the fetal cortex (Figure 3). We focused on four different genes. RC3/neurogranin expression was significantly higher in the cortex of fetuses derived from dams treated with 4 mg/kg A1254 (F(2,15) = 5.423, p = 0.0169). NSP-A expression was significantly elevated in fetuses derived from dams treated with either 1 or 4 mg/kg A1254 (F(2,13) = 8.212, p = 0.0049).

Discussion

The present study demonstrates that the commercial PCB mixture A1254 significantly reduces serum TH levels, T₄, and T₃, in pregnant rats on GD16. This developmental time occurs before the onset of thyroid function in the fetus (Fisher et al. 1977); therefore, it is reasonable to propose that this PCB-induced decrement in maternal TH would cause a reduction in the expression of genes positively regulated by TH. However, we found that PCB exposure up-regulated the expression of genes that are positively regulated by TH. These findings indicate that PCBs can activate TRs, perhaps directly, and the implication is important because inappropriate activation of TRs in the developing brain may produce adverse consequences on brain development (Kopelman 1983; Rastogi and Singhal 1976, 1979; Zoeller 2003).

Our finding that A1254 decreased circulating levels of TH in pregnant rats is consistent with previous studies showing that exposure to A1254, or specific PCB congeners, causes a reduction in circulating levels of total T₄ in pregnant rats (Meerts et al. 2002; Morse et al. 1993, 1996). Additionally, we found that serum total T₃ was also reduced in the dams by A1254, indicating the degree to which serum T₄ was reduced, because nearly 80% of circulating T₄ is derived from peripheral deiodination of T₃ (Taurog 2000). Although PCB exposure reduced serum T₄ in the dams, several descriptive measures of hypothyroidism were not altered. For example, maternal body weight, weight gain, litter size, and pup weight were all unaffected by PCB treatment in this experiment (data not shown), similar to results of our previous study (Zoeller et al. 2000). Therefore, like others, we observed a discrepancy between the ability of PCB exposure to lower serum TH levels and its ability to produce symptoms of hypothyroidism.

The present finding that fetuses derived from A1254-treated dams exhibited a significant increase in RC3/neurogranin and Oct-1 expression represents strong evidence that PCBs can produce TH-like effects in the fetal brain because maternal TH increases the expression of these genes in the fetal brain (Dowling et al. 2000; Dowling and Zoeller 2000). Considering that A1254 exposure produced a significant reduction in circulating T₄ and T₃ in the dam, this finding is fully consistent with the hypothesis that PCBs can directly activate TRs in the fetal brain. Moreover, A1254 exerted selective effects on the expression of TH-responsive genes because NSP-C, which is not influenced by TH in the fetus (Dowling et al. 2000, 2001), was not affected by A1254. Furthermore, previous work in our laboratory has demonstrated that A1254 decreases the expression of myelin basic protein, a known TH-responsive gene (Farsetti et al. 1991; Marta et al. 1998; Rodriguez-Pena et al. 1993), in the cerebellum and RC3/neurogranin in the forebrain of postnatal rats, despite the finding that these pups exhibited a decrement in maternal TH.

Figure 4. (A) Saturation analysis of 125I-T₃ specific binding (SB) to TRs in nuclei isolated from rat liver tissue, and (B) total binding (TB) obtained by incubating hepatic nuclei with increasing concentrations (1 × 10⁻¹⁰ to 8 × 10⁻⁷) 125I-T₃ (n = 3; see “Materials and Methods” for assay conditions). NSB, nonspecific binding.

Figure 5. Competitive binding of known TH receptor agonists (A) and parent PCB congeners (B) to isolated hepatic nuclei. In (A), rat liver nuclear extracts were incubated with 1.0 nM 125I-T₃ and increasing concentrations (1 × 10⁻¹⁲ M to 1 × 10⁻⁶ M) of T₃, T₄, Triac, or Tetrac; TR agonists displayed an expected order of binding affinity to isolated nuclei (T₄ > Triac > T₃ > Tetrac). In (B), isolated nuclei were incubated with 1.0 nM 125I-T₃ and increasing concentrations (1 × 10⁻⁶ M to 1 × 10⁻³ M) of one of the parent PCB congeners; no parent PCB congener exhibited significant binding to isolated nuclei. (B) is representative of results obtained from assays that tested hydroxylated and MeSO₂-PCB metabolites for their ability to displace 125I-T₃ from TRs in hepatic nuclei. These compounds also showed no significant binding to nuclear extracts. All curves are obtained from results of a single experiment and are representative of three separate experiments.

Figure 6. Noncompetitive binding analysis of parent PCB congeners binding to isolated hepatic nuclei. Assays were performed to determine whether PCBs present in A1254 were able to alter the affinity TRs for T₃. Isolated nuclei were incubated with 1.0 nM 125I-T₃ and increasing concentrations (1 × 10⁻¹² M to 1 × 10⁻⁶ M) of T₃ alone or with increasing concentrations (1 × 10⁻¹⁰ M to 1 × 10⁻⁶ M) of T₄ in the presence of 20 μM of the PCB competitor. These PCBs were unable to alter the established Kᵢ of T₃ for TRs in hepatic nuclei.
severe reduction in the circulating levels of TH (Zoeller et al. 2000). Taken together, these data indicate that A1254 can exert agonistic effects on a variety of positively regulated TH-responsive genes in different brain regions at different developmental times.

Although A1254 produced TH-like effects on the expression of RC3/neurogranin and on Oct-1 in the fetal cortex in the present study, it did not exert these effects on NSP-A expression. We previously found that NSP-A expression is significantly increased in the brain of fetal rats derived from hypothyroid dams (Dowling et al. 2000, 2001). Therefore, the present finding that NSP-A expression is increased in the cortex of fetuses exposed transplacentally to A1254 suggests that the expression of this gene is responding to low maternal T4 in PCB-treated dams, not to agonistic actions of PCBs on TRs. Previously, we showed that T4 treatment of hypothyroid dams did not restore NSP-A expression in the fetal cortex (Dowling et al. 2001). Because T4 was provided for only a short time, the interpretation was that the duration of T4 treatment was not sufficient to produce a significant reduction in cellular levels of NSP-A mRNA. However, Chan et al. (2003) have recently reported that NSP-A expression is not directly sensitive to TH in N-Tera-2 cells, indicating that NSP-A may not be directly regulated by TH. If maternal hypothyroidism increases NSP-A expression indirectly, and NSP-A is not directly regulated by TH, then our present results indicate that PCBs produce effects on the fetal brain by exerting direct TH-like effects as well as by inducing low maternal TH.

Considering these findings, we tested a number of PCB congeners and specific metabolites for their ability to bind to TRs using a well-established binding assay (DeGroot and Torresani 1975). We found that neither the parent PCB congeners nor the hydroxylated or MeSO2 metabolites significantly displaced T3 from rat hepatic nuclei. It is not likely that these observations are false negatives because the observed Ki for several control ligands, including T3, T4, Tetrac, and Triac, were all within the published range (Evans and Braverman 1986; Goslings et al. 1976; Ichikawa and DeGroot 1987). In addition, we demonstrated in preliminary studies that the PCB diluent (dimethyl sulfoxide) does not interfere with the assay; moreover, we used different diluents in initial studies and obtained results that did not differ from those reported here. Thus, our finding that individual PCB congeners or their metabolites do not displace T3 from its receptor indicates that these compounds do not interact with the TR in a competitive manner.

We employed hepatic nuclei to test whether individual PCB congeners could bind to rat TRs because the TR isoforms expressed in hepatocytes are also the predominant isoforms expressed in the fetal cortex (Bradley et al. 1992; Nakai et al. 1988). Therefore, the observation that individual PCB congeners did not displace T3 from liver nuclei suggests that they also do not displace T3 from TRs in the fetal cortex. However, Check et al. (1999) demonstrated that several hydroxylated PCB metabolites bind to the human TRβ1, although the affinity for the TR was reported to be 10,000-fold lower than that of T3. We evaluated two of these metabolites, 4′-OH-PCB-14 and 4′-OH-PCB-106, but did not find significant binding to the TRs in rat hepatic nuclei. These two studies may differ in their findings because we used TR isomers from a different species, or because both TRo1 and TRβ1 are expressed in hepatocytes (Nakai et al. 1988). Specifically, it is possible that we may not have observed significant T3 displacement if a PCB congener binds to only one of the two TRs with low affinity.

There are two major implications of the present study. First, the observation that PCB exposure selectively alters gene expression in the fetal cortex strongly suggests that PCBs can exert deleterious effects on fetal brain development regardless of the mechanism by which this effect is mediated. Because we used TH-responsive genes as end points for this study, it is likely that the observed effects reflect the ability of PCBs to disrupt TH action in the fetal brain. It will be important to determine whether PCB exposure can interfere with neurodevelopmental events by interfering with TH action.

The second major implication of our present results is that PCBs do not appear to bind to TRs in a competitive manner. We were surprised to find no individual PCB congeners or metabolites that exhibited strong binding to TRs, especially considering previous speculation about this (McKinney et al. 1987; McKinney and Waller 1998; Porterfield 1994, 2000; Porterfield and Hendry 1998). However, there is evidence that PCB congeners can affect TR activation without displacing T3. Specifically Iwasaki et al. (2002) showed that 4′-OH-PCB-106 suppressed T3-induced transactivation by TR in various cell lines. This appeared to be specific to the TR because it did not suppress glucocorticoid receptor–mediated transactivation. In addition, they showed that this PCB congener suppressed the ability of the TR to recruit the coactivator SRC-1. Because we found that this hydroxylated PCB did not displace T3 from rat TRs in the present study, these observations strongly suggest that PCBs can directly alter TR action by a mechanism that is not well understood.

Our failure to identify individual PCBs that can bind with high affinity to the rat TRs requires alternate explanations for their effects on TH-responsive genes and developmental events. Individual PCB congeners may alter TH metabolism by tissue deiodinases, thereby changing the amount of hormone available to the TR. Previous studies indicate that PCBs can increase type-2 deiodinase activity in the adult (Hood and Klaassen 2000) and fetal (Meerts et al. 2002; Morse et al. 1996) rat brain. Moreover, PCBs are also known to affect second messenger signaling in the brain by affecting calcium homeostasis, receptor-mediated inositol phosphate production, and translocation of protein kinase C (Kodavanti et al. 1993, 1994). In addition, PCBs can produce toxic effects by binding either to the aryl hydrocarbon receptor (Safe 1990) or the ryanodine receptor (Schantz et al. 1997; Wong et al. 1997). These studies demonstrate that PCBs, especially as a mixture such as A1254, clearly produce multiple effects. However, there is no evidence that these other mechanisms of PCB action can exert specific effects on TH-responsive genes.
