Abstract

Background- Suboptimal adherence to antiretroviral therapy will lead to drug resistance, treatment failure, clinical deterioration, death and failure to thrive in children. Studies conducted among children below 15 years old were limited in Ethiopia in general and in the study area. Therefore, this study aimed to assess the status of children’s adherence to ART and associated factors in the study area.

Methods- We conducted a facility-based cross-sectional study by including 282 children <15 years who received anti-retroviral therapy for at least one month. All children/caregivers who were attending the ART clinic during the data collection period were consecutively recruited for the study. Both bivariate and multivariate logistic regression were performed.

Result- Out of 282 caregivers included with their children, 226 (80.2%) were females (mean age= 38.6 and SD = 12.35). In similar, among total number of children included in the study, half (50%) were female and 246 (87.2%) were between the ages 5–14 years (mean age= 8.5 and SD = 2.64). Two hundred and forty six (87.2%) children had an adherence status of ≥95% in the month prior to the interview.

Children whose caregivers were residing in urban areas were 3.3 (95% CI: 1.17, 9.63) times more adherent to ART when compared to caregivers in rural areas. Children whose caregivers were biological parents, were 2.37(95% CI: 1.59, 3.3) times more adherent when compared with caregivers with non-biological parents. Additionally, children of caregivers who were knowledgeable about ART treatment, were 4.5(95% CI: 1.79, 9.8) times more adherent to ART than their counterparts.

Conclusion and recommendation- The adherence status of children in our study area was comparable. Biological caregivers, residing in urban areas and knowledgeable about ART treatment facilitate adherence to ART. Ongoing education about treatment and further study with multiple adherence assessment methods were recommended.

Background

According to a global HIV/AIDS report, the status of adherence to ART among HIV infected children varied from 65.0% to 90.0% (1), 75.0% in developing countries(2) and 88.8% in Ethiopia(3).

An important factor in achieving treatment success is maintaining optimal adherence to ART (4–6). Adherence to antiretroviral treatment is defined as taking 95% or more of the prescribed doses on time and in the correct way, either with or without food (5,7).

Poor adherence to ART will lead to an increased risk of drug resistance, treatment failure and clinical deterioration with increased premature death in children(9,10,12).

The causes of poor adherence to ART among pediatric patients are complex and interrelated factors. Total dependency of the child on caregiver, pill burden and dosing frequency, treatment side effects, poor
health literacy, limited access to ART (10–12), socioeconomic status of the caregiver, substance use and access to service delivery) (13) (14) are among some factors.

The emergence of drug resistant HIV virus among children adds an enormous period. It may create an introduction of resistant HIV virus to the general population as the child with HIV grows to adolescence and young adulthood (15)(16).

Therefore, designing strategies for maintaining the optimal status of adherence among children, is essential to ensure treatment success. However, the task requires careful assessment of the status of adherence and age specific factors (17). Studies conducted among children below 15 years of age are limited in Ethiopia, in general and in the study area. Additionally, adherence is not static and can vary with time on treatment, making assessing adherence status crucial (14). Moreover, viral load was added as one variable in this study, which has not been researched in previous studies. Therefore, this study aimed to examine the status of adherence and associated factors among children under the age of 15 years in the study area.

**Methods And Materials**

A facility based cross sectional study was conducted from April 1 to May 10, 2020 in the Sebeta, Teji, Tullu Bollo and Waliso towns which are located 20 km, 50 km, 65 km and 114 km away from Addis Ababa, respectively. These towns were, in the southwestern direction along the main road from Addis Ababa to Jimma. In total, there are 8 public ART sites included in all 4 towns. Three of the public ART sites are within Sebeta town (Sebeta HC provide ART services for 41 under 15 children, while 21 and 09 are served in Alemgena and Tefki HC respectively. Two public ART sites are found in Tullu Bolo town. Tullu Bolo General Hospital serves 25 HIV positive children and Tullu Bolo HC provides services for 17 HIV positive children. Teji town also, has Teji HC who provide services for 18 under 15 children. The rest are found in Waliso town, (St. Lukes Referral Hospital serves 130 and Waliso HC serves 29 under 15 children). In total, 290 children are on ART in those health facilities. These health facilities have case managers and adherence supporters.

Sample size was calculated by considering the ratio of unexposed to exposed 0.6, outcome in the exposed group 49.0%, and outcome in the unexposed group 29.5%(18) for both objectives. Then after, largest sample was selected, with a 10.0% nonresponse rate, giving a sample size of 254. There were 290 children on ART in these health facilities, and all were include.

Pretested and structured questionnaires, using face- to - face interviews, were held for data collection. The questionnaires were adapted from previously conducted related studies. Some changes were made after reviewing the relevant literature. The questionnaire was translated to Afan Oromo and Amharic for better understanding by the respondents.
Pretest of the questionnaire was performed on 5.0% (14) of the caregivers in Awash Health Center. Medical records were reviewed to collect clinical data such as WHO clinical stages, regimen type, viral loads and the CD4 counts of children.

Data were collected by 8 clinical nurses. The data collection process was supervised by one health officer and one BSc nurse. Adherence and exposure variables were measured by the caregivers’ or children's report of a one-month recall of missed doses prior to the date of the interview. The questionnaires were coded and entered into the EPI data statistical software and thereafter, exported to SPSS Windows version 23 for further analysis. Data were summarized and presented using descriptive and analytic statistics. Bivariate and multiple logistic regressions were computed to identify the presence and strength of associations. Variables with a p value <0.25, in binary logistic regression, were subjected to multiple logistic regression for analysis. However, before multiple logistic regression, collinearity diagnostic test was done and no multicollinearity (maximum Variance Inflation Factor (VIF) =3.883). On the other hand, Breslow-Day test showed, there significant synergetic interaction between two variables (i.e. child relationship with caregiver vs caregiver ART history). As a result, the stratum specific odds ratio was considered to measure the strength of the association. At the end, multiple logistic regression (odds ratios with 95% CIs were computed) and variables with p-values less than 0.05 were considered significantly associated with the dependent variable. Finally, the model was fitted using the backward elimination method, and the Hosmer-Lemeshow goodness of fit test indicated a p-value of 0.47).

Operational Definition

**Adherent to ART** – when the child has missed ≤ 1 dose or takes ≥95% of ART in the month prior to the interview.

**Non adherent to ART**- missing at least two doses or takes <95% of ART in the month prior to interview.

Caregiver - Parent/guardian or person in charge of routinely administering antiretroviral drugs to children on ART.

**Baseline CD4 count**- CD4 count done when a child started ART(7).

**Current CD count**- CD4 count done within 6 months of data collection(7).

**Knowledge about ART**- Those respondents who scored greater than or equal to the mean for the knowledge questions were considered knowledgeable; otherwise, they were not.

**Care giver/child substance use**- if caregiver/child use either of alcohol, khat, cigarettes or other substance in the month prior to data collection.

Ethical considerations

Ethical clearance letters were obtained from the Ethical Review Committee, Jimma University, Institute of Health. Each health facility was contacted after the official letter was submitted. The interviews were held
after verbal informed consent and assurance of confidentiality.

**Results**

**Sociodemographic characteristics of the study participants**

Of the 290 study participants, 282 children, along with their caregivers, were included in the analysis, yielding a response rate of 97.2%. Four caregivers were excluded because they did not appear in the health facility during the data collection period. Three questionnaires were discarded as they were not complete (caregivers did not know the dosing history for the past month) and one caregiver was not willing to respond to the questionnaire. Among the respondents, 226 (80.2%) of the caregivers were females, and the mean age of the respondents was 38.6 years (SD =12.35). Out of the total respondents, 176 (62.5%) were married and 31 (11.0%) were single. One hundred and fifty-eight (56.0%) of the caregivers attended primary education. Two hundred and nine (74.1%) of the caregivers were urban dwellers. Among the children included in the study, half (50.0%) were female, 246 (87.2%) were 5–14 years old with the mean age of 8.5 years (SD = 2.64). One hundred and eighty three (64.9%) children are currently attending 1-4 grades. (Table 1).

*Table 1* - Socio demographic characteristics of study participants, central Ethiopia, April 1- May 10, 2020. (*n=282*)
| Variables                      | Frequency | Percentage |
|--------------------------------|-----------|------------|
| Caregivers Sex                |           |            |
| female                        | 226       | 80.2       |
| male                          | 56        | 19.8       |

| 1-4 grades                    | 183       | 64.9       |
| 5-8 grades                    | 15        | 5.4        |

**Clinical characteristics of study participants**

Among the children who participated in this study, 102 (36.2%) started ART at WHO clinical stage I and 273 (96.8%) were currently on WHO stage I. At initiation of ART, 142 (50.4%) children had a CD4 count of >500 cells/mm³. During data collection, viral load was done for 206 (73%) children and out of these, high viral load (≥ 1000 copies/ml) was detected in 55 (19.5%) children. (Table 2)
Variables

| Variables                        | No  | %   |
|----------------------------------|-----|-----|
| Baseline CD4 count of the child  |     |     |
| ≤200                             | 26  | 9.2 |

*Table 2- Clinical characteristics of study participants, in central Ethiopia, April 1- May 10, 2020. (n=282)*

**ART and other drug history of the children**

Among the children included in the study, 279 (95.8%) were on 1st line ART medication and 195 (69.2%) of the children were taking 2 pills per day (morning and night), while 38 (13.4%) of the children were taking 3 doses daily. The current study also showed that among children who took part in the study, 247 (87.6%) had been on ART for more than one year. Concerning CPT, 200 (70.9%) of the children were not on CPT at the time of data collection. *(Table 3).*
| Variables                        | No | %   |
|---------------------------------|----|-----|
| Duration of child on ART        |    |     |
| <1yrs                           | 35 | 12.3|
| >=1yrs                          | 247| 87.6|
| Line of treatment               |    |     |
| 1<sup>st</sup> line             | 270| 95.8|
| 2<sup>nd</sup> line             | 12 | 4.2 |
| Number of pills child is taking/day |    |     |
| 1 pills                         | 38 | 13.4|
| 2 pills                         | 195| 69.2|
| ≥ 3 pills                       | 49 | 17.3|
| Is child taking CPT             |    |     |
| Yes                             | 82 | 29.0|
| No                              | 200| 70.9|

*Table 3- ART and other drug history of study participants in central Ethiopia, April 1-May 10, 2020. (n=282).*

Among children on ART in study the area, 176 (62.4%) are on AZT-3TC-NVP and 47 (15.6 %) are on AZT-3TC-EFV regimen. Only 6 (2.0%) of the children who are currently on ART have been taking a combination of AZT based kaletra (boosted drug with Protease inhibitor).

**Adherence status of the children to ART**

Based on the caregivers’ report, a total of 246 (87.2%, (95% CI: 83.3%- 91.1%) children had an adherence status of ≥95% in the month prior to interview. The status of adherence to ART among children in the past three and seven days before the interview date was 98.9% and 95.8%, respectively.

**Reasons for non-adherence**

According to the current study, 36 (12.8%) of the children missed at least 2 doses out of their prescribed dose preceding for the month before data collection. The commonly mentioned reasons were: fear of stigma (21.3%), caregiver's forgetfulness (14.2%), child's refusal to take the drugs (13.8%) and run out of medication (13.8%). *(Fig 1)*

**Distance from health facility and mode of transportation**

Out of the total caregivers/children who participated in the study, the majority, 219 (77.7%), came from less than 10 km and 113 (40.1%) of the participants came to the health facility on foot to refill medication. *(Table 4)*
Table 4- Distance from health facility and mode of transportation of study participant to refill medication, central Ethiopia, May 10, 2020.

Factors associated with adherence to ART

In multiple logistic regression, the residence area of caregivers, blood relationship between children and caregivers and knowledge of caregivers about ART treatment, were significantly and independently associated with adherence. Children whose caregivers resided in urban areas were 3.3 times more likely adherent to ART than their counterparties [AOR = 3.3(95% CI: 1.17, 9.63)]. Children whose caregivers were biological parents were 2.37 times more likely to be adherent than those whose caregivers were non-biological parents [AOR = 2.37(95% CI: 1.59, 3.2]. The present study also showed that if the caregiver was knowledgeable about ART treatment, the child was 4.5 times more likely to be adhere to ART than their counterpart [AOR = 4.5(95% CI: 1.79, 9.8)]. (Table 5)

Table 4- Crude and adjusted odds ratios and 95% Confidence Intervals (CIs) of explanatory variables of adherence to HAART in the study area, central Ethiopia, April 1 May 10, 2020. (n=282).
### Discussion

According to this study, 87.2% of children had an adherence status of $\geq 95\%$ in the month prior to the interview. This is higher than the finding of global pooled estimation, which is 65.0% - 75.0% (9). This difference could be due to the context of the study area (i.e., specific study area among children living in...
almost similar socio-demographic characteristics vs global context). In addition, the global pooled estimate used secondary data. However, our finding was comparable with an studies in East Africa 90%.0(19); in Southeastern Nigeria, 91.0%(20); Ethiopian national pooled prevalence of optimal HAART adherence 88.8% (3); Eastern Ethiopia, 90.7% (21), in Mekelle Hospital, Tigray, 90.7% (22); in Gondar University Hospital and Gondar Poly Clinic, 90.4%(23); and in Addis Ababa, 86.9%(24). However, the finding of the current study was higher than the finding of study conducted in India, which revealed an overall adherence of 82.1% (25). This difference might be due to the study design (cross-sectional vs cohort). It was also higher than that in a study in Uganda which reported an overall adherence status of 79.1%(26), South Wallo zone, provided an adherence status of 78.6%(18), and in Fiche Hospital, showed an adherence rate of 74.0%(27). This difference could be due to the small sample size in Fiche Hospital ((120 vs 282). Again, higher adherence rate was observed in our study when compared with finding of study conducted in the ART clinic of Tikur Anbessa Hospital, (i.e. an adherence rate of children to ART was 34.8%) (28). This difference was due to adherence assessment methods (caregiver’s report vs unannounced home based pill count). In general, the current study finding of the adherence status of children to ART is below the recommendation of the WHO, which recommended that ≥90% of people on ART should be adherent to ART to fully benefit from ART(5).

Regarding associated risk factors for non-adherence, the current study showed that children whose caregivers were biological parents were 2.37 times more adherent than those whose caregivers were non-biological parents. [AOR= 2.37, 95 CI= (1.59-3.2)]. This finding is similar to the cross-sectional study finding conducted in Hiwot Fana and Dil-Chora Referral Hospital in eastern Ethiopia, which revealed that children whose caregivers were biological parents were more adherent.

The other independently associated risk factor for adherence to ART among children identified by this study was caregivers’ knowledge of ART. Accordingly, we found that children with knowledgeable caregivers were 4.5 times more adherent than those children whose caregivers were not knowledgeable [AOR 4.5 95% CI (1.7-9.8)]. Our finding is similar to the study finding conducted in Hiwot Fana and Dil-Chora Hospital, which revealed that caregivers of children with good knowledge about the disease were 7.3 times [AOR = 7.3] adherent than their counterparts(21).

Again, our finding is also similar to the finding of a study conducted in India that came up with, children whose caregivers had good knowledge about ART treatment were 14.7 times more adherent (25). A similarly study conducted in south Wollo zone justified our finding [AOR=2.72] (34). Our finding is again in line with the study finding conducted at University of Gondar Hospital and Gondar Poly Clinic, which showed that children of knowledgeable caregivers had 4.7 times more adherent to ART than their counterparts [AOR=4.7](23). This implies that making caregivers knowledgeable about the importance of ART treatment through ongoing and extensive counseling is mandatory to make children more likely to benefit from good adherence to ART.
The current study also showed that children residing in urban areas were 3.2 times more adherent to ART than those residing in rural. [AOR=3.2, (95% CI 1.17-9.63)]. This finding is supported by a study conducted in Tanzania that reported, suboptimal to ART was observed among children in the rural context of the Mwanza region(29). However, our study is contradicts a comparative study conducted between rural and urban children, in South Africa that revealed, rural children were more adherent to ART (93.1% vs 88.0%)(30). This difference might be due to the study design (cross-sectional vs cohort). In general, this implies that urban dwellers have more access to information and education when compared with rural dwellers.

Our study is not free of limitations. There might be an overestimation of adherence status in our study because of recall and social desirability bias. Thus, to minimize this bias we used non ART providers as data collectors. Additionally, we did not assess adherence related to the correct timing of ART drug administration. Again, the cross-sectional nature of the study also hinders the causal relationship between adherence status and associated factors.

**Conclusion And Recommendation**

The adherence status of the children to ART in our study area was comparable. Children residing in urban areas, with biological caregivers and children of knowledgeable caregivers were more adherent to ART. Ongoing counseling of non-biological parent and for those who come from rural areas is mandatory. Other studies should be conducted using multiple and more objective adherence assessment tools.

**Declarations**

**Acknowledgment**

My heartfelt thanks to Jimma University Institute of Public Health Department of Epidemiology for giving us this opportunity. My deepest gratitude again goes to my advisors Habtemu Jarso (assistant professor) and Mr.Zarihun Kura for their corrective comments
