ABSTRACT

BACKGROUND AND PURPOSE: Prediction of hemorrhagic transformation in acute ischemic stroke could help determine treatment and prognostication. With increasing numbers of patients with acute ischemic stroke undergoing multimodal CT imaging, we examined whether CT perfusion could predict hemorrhagic transformation in acute ischemic stroke.

MATERIALS AND METHODS: Patients with acute ischemic stroke who underwent CTP scanning within 12 hours of symptom onset were examined. Patients with and without hemorrhagic transformation were defined as cases and controls, respectively, and were matched as to IV rtPA administration and presentation NIHSS score (\(\pm 2\)). Relative mean transit time, relative CBF, and relative CBV values were calculated from CTP maps and normalized to the contralateral side. Receiver operating characteristic analysis curves were created, and threshold values for significant CTP parameters were obtained to predict hemorrhagic transformation.

RESULTS: Of 83 patients with acute ischemic stroke, 16 developed hemorrhagic transformation (19.28%). By matching, 38 controls were found for only 14 patients with hemorrhagic transformation. Among the matched patients with hemorrhagic transformation, 13 developed hemorrhagic infarction (6 hemorrhagic infarction 1 and 7 hemorrhagic infarction 2) and 1 developed parenchymal hematoma 2. There was no significant difference between cases and controls with respect to age, sex, time to presentation from symptom onset, and comorbidities. Cases had significantly lower median rCBV (8% lower) compared with controls (11% higher) (\(P = .009\); odds ratio, 1.14 for a 0.1-U decrease in rCBV). There was no difference in median total volume of ischemia, rMTT, and rCBF among cases and controls. The area under the receiver operating characteristic was computed to be 0.83 (standard error, 0.08), with a cutoff point for rCBV of 1.09.

CONCLUSIONS: Of the examined CTP parameters, only lower rCBV was found to be significantly associated with a relatively higher chance of hemorrhagic transformation.

ABBREVIATIONS: AIS = acute ischemic stroke; rCBF = relative cerebral blood flow; rCBV = relative cerebral blood volume; HI = hemorrhagic infarction; HT = hemorrhagic transformation; IQR = interquartile range; rMTT = relative mean transit time; ROC = receiver operating characteristic analysis; PH = parenchymal hematoma.
MR imaging and blood-brain barrier permeability measures on CTP are also under investigation to formulate predictive models for HT.

In this study, we sought to investigate the hypothesis that there are inherent characteristics of ischemic brain tissue measurable by CTP that might predict hemorrhagic transformation. We evaluated the value of CBV, CBF, MTT, and volume of affected brain tissue toward prediction of HT in ischemic stroke.

**MATERIALS AND METHODS**

This was an institutional review board–approved study conducted at a single academic stroke center receiving >700 patients with ischemic stroke/TIA annually. The study extended from July 2009 to February 2010, and a cohort of all adult patients presenting with symptoms consistent with stroke/TIA within 12 hours of onset who underwent emergent CTP imaging was selected. At our institution, all patients with stroke presenting within 12 hours of symptom onset under CTP imaging. Patients with contraindications to CTP (ie, anaphylactic reaction to contrast, patients with known poor kidney function) were excluded. In addition, patients with a final diagnosis of TIA and those with infratentorial/bilateral/lacunar strokes were excluded. In this study, only patients with a discharge diagnosis of AIS were included in the final cohort.

The medical records were reviewed to obtain age, sex, medical history (hypertension, diabetes, dyslipidemia, coronary artery disease, TIA, stroke), smoking history, medication use, signs and symptoms on arrival, stroke severity at presentation (NIHSS score), use of IV rtPA and endovascular therapy, in-hospital outcome, and functional status on discharge (measured by the mRS). Follow-up noncontrast CT or MR imaging or both were reviewed to document the development of hemorrhagic transformation. “HT” was defined according to the European Cooperative Acute Stroke Study on NCCT as an area of increased attenuation within an area of low attenuation in a typical vascular distribution. On MR imaging, HT was identified by the presence of blood-product signal characteristics on T1, T2, and gradient-echo sequences. “Hemorrhagic transformation” was defined as per the European Cooperative Acute Stroke Study I and II trials and was classified as HI and PH. This was further subdivided into HI 1 and HI 2 and PH 1 and PH 2. “HI 1” was defined as small petechiae along the peripheral margins of infarct. Confluent petechiae within the infarcted region but without mass effect were classified as HI 2. “PH 1” was defined as hematoma with a mass effect of <30% of the infarct volume, and a PH with a mass effect of >30% of infarct volume was classified as PH 2.

The CTP imaging studies of every research patient were analyzed. CTP images were processed by using Vitrea software (Vital Images, Minnetonka, Minnesota) by using a delay-insensitive algorithm (see “Imaging Protocol” below for further details). A freehand region of interest was used to outline the total brain tissue at risk of ischemia as defined by increased MTT, decreased CBF, and preserved CBV of the ischemic area to the contralateral normal side. The outlined region of interest shows increased MTT, decreased CBF, and preserved CBV in each respective panel.

**FIG 1.** CTP maps. A, volume at risk of ischemia (volume computed from the area and thickness of each section [5 mm]). B, MTT. C, CBF. D, CBV. CTP images of a patient with AIS with right MCA occlusion. rMTT, rCBF, and rCBV are computed by normalizing MTT, CBF, and CBV of the ischemic area to the contralateral normal side. The outlined region of interest shows increased MTT, decreased CBF, and preserved CBV in each respective panel.

**Table 1: Characteristics of study cohort**

| Characteristics                | Total Patients (n = 83) |
|-------------------------------|------------------------|
| Female (No.) (%)              | 37 (44.6%)             |
| Age (yr) (median) (IQR)       | 72 (61–80)             |
| Time (min) to arrival (median) (IQR) | 124 (64–314) |
| Stroke severity on arrival (NIHSS) (median) (IQR) | 7 (3–15) |
| Medical history               |                        |
| Hypertension                  | 77.8%                  |
| Diabetes                      | 26.8%                  |
| Dyslipidemia                  | 52.4%                  |
| Stroke/TIA                    | 34.9%                  |
| Coronary artery disease       | 24.4%                  |
| Medication history            |                        |
| Antiplatelets                 | 45.0%                  |
| Anticoagulants                | 10.1%                  |
| Thrombolysis done             | 27.7%                  |
| Functional outcome (mRS) at discharge (median) (IQR) | 3 (1–5) |
| Duration (days) of hospital stay (median) (IQR) | 5 (3–8) |
Table 2: Comparison of cases and controls (matched on IV rtPA and NIHSS ± 2)

| Characteristics  | Cases (n = 14) | Controls (n = 38) | P Value |
|------------------|---------------|------------------|--------|
| Age (yr) (median) (IQR) | 71 (61–77) | 75 (65–84) | .15 |
| Female (N%) (%)  | 4 (28.6%) | 19 (50.0%) | .22 |
| Time (min) to arrival (median) (IQR) | 127.5 (25–39) | 134 (67–547) | .23 |
| Arrival systolic BP (mm Hg) (median) (IQR) | 146.5 (136–177) | 153 (134–162) | .87 |
| Arrival diastolic BP (mm Hg) (median) (IQR) | 81.5 (75–98) | 83 (66–102) | .74 |

| Mean ± SD | 1.87 (0.43) | 2.20 (1.70) | .4873 |
| rCBF (median) (IQR) | 0.54 (0.40–0.63) | 0.58 (0.46–0.70) | .5079 |
| Mean ± SD | 0.52 (0.34) | 0.58 (0.35) | .0093b |
| rCBV (median) (IQR) | 0.92 (0.83–1.07) | 1.11 (1–1.29) | .0093b |
| Mean ± SD | 0.93 (0.13) | 1.19 (0.36) | .0093b |

Note: —MTTv indicates volume at risk of ischemia.

a Seven cases (accounting for 13 controls) and 1 additional control who received endovascular therapy were excluded.

b Statistically significant (P < .05).

RESULTS

Characteristics of the Patient Population

Eighty-three patients with stroke were enrolled in the study. The characteristics of the cohort are presented in Table 1. Of the total cohort, 16 (19.3%) patients developed HT during their hospital stay. Of these, 37.5% had an early HT (HT within 36 hours of symptom onset). The median duration to the development of HT was 38.7 hours (IQR, 18.8–52.4 hours).

Characteristics of Matched Cases and Controls

After matching for IV rtPA administration and presenting NIHSS score (± 2), 38 controls were found for 14 cases (no controls were found for 2 patients with HT). There were no differences between cases and controls with respect to age, sex, vital parameters on presentation, history of disease or medication use, initial laboratory investigations, and smoking history (Table 2). Cases had a longer hospital stay (median, 8.5 days; IQR, 7–12 days) compared with controls (median, 5 days; IQR, 3–8 days; P = .012). There core infarct regions, based on the CBV).26 However, our sample size limited our ability to make multiple comparisons, and we, therefore, chose to proceed with measurements encompassing the entire ischemic region, as was done by previous authors.27

A matched case-control cohort was created. Any patient who had HT on follow-up imaging (CT or MR imaging) was considered a “case.” Corresponding controls (±4) were selected for each of the cases by matching based on IV rtPA administration and presenting NIHSS score (±2). The matching was performed by using SAS (SAS Institute, Cary, North Carolina) (percentage match, greedy method).

Nonparametric analysis was performed to compare cases and controls by using the Wilcoxon rank sum test. For the initial analysis, all patients with endovascular therapy were excluded. CTP parameters were compared for cases and controls by using the Wilcoxon rank sum test, and P values < .05 were considered significant. Analysis was then repeated, including endovascular patients as well, but excluding those with SAH or PH that might be interpreted as procedure-related (1 endovascular patient with PH was therefore excluded). Conditional logistic regression was used to analyze the effect of CTP parameters on the development of hemorrhagic transformation, and ROC curves were created. All analyses were performed in SAS 9.2/IMP 9 (SAS Institute).

Imaging Protocol

CTP imaging was performed on a 64-detector CT scanner (Brilliance; Philips Healthcare, Best, the Netherlands) following an initial noncontrast CT scan. This involved successive gantry rotations during IV administration of 50 mL of ioversol (Optiray 350; Mallinckrodt, St. Louis, Missouri) at 5 mL/s followed by a 40-mL saline push. Coverage of 40 mm was obtained, with 8 × 5 mm thick sections, 32 × 1.25 mm collimation, and standard reconstruction. Acquisition parameters were 80 kV(peak), 150 mAs; 2-second cycle time; 30 cycles; 0.4-second rotation; and FOV, 230.

Postprocessing of images was performed by using Vitrea software, Version 3.0.1 (Vital Images). We used whole values derived from each region of interest rather than threshold values, because we have found that data derived from our commercial CTP software is more semiquantitative in nature and we feared that choosing a set uniform threshold across all patients would not account for differences in cardiac output, anatomy, and timing of injections among individual patients. Visually matched areas of increased MTT and decreased CBF were, therefore, outlined as ischemic areas, and all values were then reported as relative to the contralateral hemisphere, to account for potential interpatient variability noted above. The Vitrea software automatically chooses the selected arterial input function and venous output function (typically a proximal A2 vessel and a large dural sinus, respectively). These are verified by the technologist to be anatomically accurate and to result in correct time-to-peak maps of arterial and venous time-intensity curves. In rare cases in which there are discrepancies in the automatic arterial input function and venous output function locations, the arterial input function and venous output function are manually selected by the technologist. We additionally verified each arterial input function and venous output function for all patients included in the study.
was a statistically nonsignificant difference between functional outcome assessed at discharge between cases (median mRS score, 5; IQR, 3–5) and controls (median mRS score, 3.5; IQR, 1–5; P = .11). Of the 14 cases, 13 had HI (7 HI 1 and 6 HI 2) and 1 case developed PH 2. Seven cases and 1 control were noted to have undergone endovascular therapy for acute ischemic stroke.

Comparison of Cases and Controls

All cases and controls who had undergone endovascular therapy were excluded (7 cases [accounting for 13 controls] and 1 additional control who received endovascular therapy were excluded). rCBV represents CBV of the ischemic area normalized to the contralateral side. The cutoff point indicates the threshold at which rCBV can predict HT with optimal sensitivity and specificity.

Table 4: Comparison of CTP parameters for matched cases and controlsa

| Parameter       | Cases (n = 13) | Controls (n = 36) | P Value |
|-----------------|---------------|------------------|---------|
| MTTv (median)   | 234.9 (178.2–326.15) | 183.55 (84.83–265.83) | .1968   |
| Mean ± SD       | 233.32 (111.53) | 186.61 (116.72) |         |
| rMTT (median)   | 2.06 (1.69–2.39) | 1.8 (1.55–2.17) | .4020   |
| Mean ± SD       | 2.00 (0.40) | 2.16 (0.42) |         |
| rCBF (median)   | 0.45 (0.39–0.59) | 0.53 (0.42–0.70) | .2572   |
| Mean ± SD       | 0.48 (0.12) | 0.54 (0.16) |         |
| rCBV (median)   | 0.92 (0.78–1.03) | 1.09 (0.97–1.17) | .0037b  |
| Mean ± SD       | 0.92 (0.17) | 1.13 (0.33) |         |

Note: MTTv indicates volume at risk of ischemia. aExcluding cases with both endovascular therapy and SAH/PH (n = 1) and their corresponding controls (n = 2). bStatistically significant (p < .05).

DISCUSSION

The incidence of HT has been reported to vary between 2% and 44% of patients with ischemic stroke,5,11,24 and the 19.3% rate observed in our study falls within this range. Besides thrombolytic therapy, HT has been associated with age younger than 65 years,28 hyperglycemia,29 acute hypertension30 and blood pressure variability,31 low levels of coated platelets,32 and cardioembolic stroke subtype.33 As new avenues are explored to stretch the time window for beneficial therapy,34 there is an increasingly acute need to accurately predict the likelihood of HT in every patient eligible for intervention to judicially triage these patients to available therapies while reducing complications.

Prediction of HT by reduced pretherapeutic CBF, an inherent characteristic of the stroke itself, was first suggested by Ueda et al15 by using SPECT. A reduction in CBF to 50% of normal was considered as the critical value for developing HT.36 Gupta et al37 in their study of 23 patients with symptomatic stroke or carotid stenosis concluded that mean ipsilateral CBF < 13 ml/100 g per minute was the cutoff for developing HT. In our cohort, we found that rCBV rather than rCBF was the strongest predictor of HT. This is similar to reports of rCBV (rather than rCBF) being a stronger predictor of penumbra viability in patients with AIS,46 with similar38 or even lower39 values reported by authors for rCBV in patients with HT. In other words, indicators of penumbra viability may also indirectly predict HT, which would be expected to occur more frequently in infarcted core rather than salvageable penumbra regions. We found in our patients that a cutoff rCBV of at least 0.98 could predict development of HT in patients with AIS with 72% specificity.

The role of imaging in acute stroke is ever-expanding.40,41 Many modalities...
have shown promise in delineating both the extent of viable brain tissue within the area at ischemic risk as well as in predicting HT. The high risk of HT was associated in the past with an M1 MCA occlusion and lack of collateral flow evaluated by transcranial Doppler, SPECT, and clinical criteria (Toronto Embolic Scale).20 More recently, BBB permeability studies via MR and CTP imaging have been shown to have a high sensitivity for predicting symptomatic HT.23,42 The ROC for rCBV in our study suggests that CBV may also predict HT. The utility of this finding lies in the fact that CT imaging is already a part of the imaging protocol in a large number of tertiary care institutions. CTP as an add-on can be performed easily and quickly in an emergent setting, while providing information about tissue-level hemodynamics, extent of penumbra, and final infarct size.43 Should our findings be replicated on a larger scale, an additional utility would be prediction of HT, which could further guide emergent treatment decisions for patients with acute stroke.

Limitations

There are several limitations to this study. This was a retrospective study. Effects of stroke severity at presentation and IV rtPA administration were controlled for by matching; however, this reduced the final cohort size. No adjustments were made for specific anatomic locations of perfusion parameters and region-specific risk of HT. Our results represent only a single-institution experience and have not been validated and may, therefore, not be representative of community practice.

CONCLUSIONS

Our data suggest that CTP imaging and, in particular, low rCBV can predict HT in patients with AIS. Should this exploratory analysis be validated in larger studies, initial multimodal CT imaging, including CTP, could be used to triage patients at high risk of HT to treatments less likely to further exacerbate their inherent risk of impeding intracerebral hemorrhage.
