Research article
Abstract

**Background:** Chicken skeletal muscle is an important economic product. Late stages of chicken development are the main period that affects meat production. lncRNAs play important roles in controlling the epigenetic process of growth and development. However, studies on the role of lncRNAs in the late stages of chicken breast muscle development are still lacking. In this study, in order to study the expression characteristics of lncRNAs during chicken muscle development, 12 cDNA libraries were constructed from Gushi chicken breast muscle samples from 6-, 14-, 22-, and 30-week-old chickens.

**Results:** Therefore, a total of 1,252 new lncRNAs and 1,376 annotated lncRNAs were identified. Furthermore, 53, 61, 50, 153, 117, and 78 DE-lncRNAs were found in the W14 vs. W6, W22 vs. W14, W22 vs. W6, W30 vs. W6, W30 vs. W14, and W30 vs. W22 comparison groups, respectively. After GO enrichment analysis of the DE-lncRNAs, several muscle development-related GO terms were found in the W22 vs. W14 comparison group. Furthermore, it was found that the MAPK signaling pathway was one of the most frequently enriched pathways in the different comparison groups. In addition, 12 common target DE-miRNAs of DE-lncRNAs were found in different comparison groups, some of which were muscle-specific miRNAs, such as gga-miR-206, gga-miR-1a-3p, and miR-133a-3p. Interestingly, the precursors of four newly identified miRNAs were found to be homologous to lncRNAs. Furthermore, we found some ceRNA networks associated with muscle development-related GO terms. For example, the ceRNA networks containing the DYNLL2 gene with 12 lncRNAs that targeted 2 miRNAs. In addition, we also constructed PPI networks, such as IGF-1-EGF and FZD6-WNT11, etc.

**Conclusions:** This study for the first time revealed the dynamic changes of lncRNA expression in Gushi chicken breast muscle at different periods, and reveal the MAPK signaling pathway play a vital role in muscle development. Furthermore, MEF2C and its target lncRNA may be involved in muscle regulation through the MAPK signaling pathway. This research provided valuable resources for elucidating post-transcriptional regulatory mechanisms to promote the development of chicken breast muscles after hatching.

**Background**

Muscle, especially skeletal muscle, is an important part of the animal [1]. In livestock production, skeletal muscle is an important economic product for human consumption. After birth, muscle weight continuously increases, and the growth of skeletal muscle is mainly achieved by increasing the hypertrophy of existing muscle fibers [2]. Compared with the embryonic stage, the development of chickens from the market stage to the elimination stage (referred to as late development) after hatching is an important period that affects meat production [3]; therefore, it is essential to study skeletal muscle growth and development during the postnatal late development of important agricultural species.

Muscle development is a complex multistage process in which many genes cooperate to regulate each stage [4]. Several candidate genes, such as the growth hormone secretagogue receptor (GHSR) [5],
insulin-like growth factors (IGFs) [6], transforming growth factor beta 2 (TGFβ2) [7], and myocyte enhancer factor 2B (MEF2B) [8], have been identified to play important roles in the growth of chickens. Although many genes play important roles in chicken muscle growth, studies have shown that only a small percentage (1-2%) of the genome encodes proteins in mammals, and tens of thousands of intergenic sites are transcribed into noncoding RNA [9]. In the past few years, regulatory RNAs, such as miRNAs, piRNAs, snoRNAs, and long noncoding RNAs (lncRNAs), appear to play roles in many important biological processes [10]. In complex organisms, lncRNAs contain hidden regulatory information that can play a role in the regulation of gene expression [11]; therefore, lncRNAs are important molecules that can affect the growth and development of chicken skeletal muscle.

LncRNAs are a class of non-protein-coding transcripts that are more than 200 bp in length [12]. Several lncRNAs have been shown to be expressed during development and have been shown to play an important role in epigenetic processes that control differentiation and development. For example, as one of the earliest identified lncRNAs, H19 also plays a regulatory role in various growth and development processes [13]. MUNC is a lncRNA that promotes skeletal muscle production by stimulating the adjacent myogenic differentiation antigen (MyoD) gene in C2C12 cells [14]. A novel lncRNA, Irm, has been shown to interact with MEF2D to enhance myogenic differentiation [15]. LncRNAs can exert cis-regulatory effects in biological processes. For instance, it has been indicated that lncRNA-Six1 cis-regulates the Six1 gene and encodes a micropeptide to activate Six1, thereby promoting cell proliferation and participating in muscle growth [16]. In addition, lncRNAs can also play a trans-regulatory role in biological processes. For example, the noncoding RNA H19 can be used as a trans-regulator of IGF2 [17]. Moreover, lncRNAs can also act as ceRNAs to protect mRNAs and act as a molecular sponge to inhibit miRNA targeting of mRNAs. For example, InclRS1 acts as a sponge of the miR-15 family, regulating the expression of insulin receptor substrate 1 (IRS1), thereby promoting skeletal muscle production [18]. Although an increasing number of lncRNAs have been characterized by high-throughput sequencing studies, there are few reports on the regulation of lncRNAs in chicken muscle development. Therefore, it is important to study the expression characteristics of lncRNAs during chicken muscle development.

Gushi Chicken is an excellent variety of egg- and meat-providing chicken native to Gushi County, Henan Province, China. Gushi chicken is tender and delicious, with a fresh and unique flavor, the eliminated hen is often used as meat. Although Gushi chickens have many excellent characteristics, their growth rate is slightly slower than commercial broiler, our previous histological study of this type of breast muscle showed that before 22 weeks of age, muscle fiber diameter grew rapidly, and after 22 weeks of age, the relationship between the diameter and density of the breast muscle fibers remained balanced [19]. To understand and control the growth and development of Gushi chicken skeletal muscle, we must understand the molecular regulation mechanism of different stages of skeletal muscle development. In this study, we identified lncRNAs by deep-sequencing data from four different stages (6, 14, 22, and 30 weeks) of Gushi chicken skeletal muscle development. Differentially expressed lncRNAs were used to predict cis- and trans-target genes to construct potential lncRNA-mRNA interaction networks and explore important signaling pathways. Then, the lncRNA data was combined with mRNA and miRNA data to construct potential lncRNA-miRNA-mRNA interaction networks and explore the regulatory networks that
play a role in chicken skeletal muscle development. In summary, this study identifies differentially expressed lncRNAs at different stages of postnatal late developmental and provides predictions about the associated interaction networks, which can be used to further study the molecular regulation mechanism of chicken muscle development.

## Results

### Identification and characterization of lncRNAs

Based on the Illumina HiSeq 2500 platform, the lowest 89,496,872 raw reads were obtained from each library, with a clean base ranging from 12.75 Gb to 16.66 Gb and an error rate of 0.01 or 0.02 (Table S1). To generate a complete annotation of the noncoding transcriptome of the Gushi chicken breast muscle tissue beyond the currently annotated transcriptome, we first used Cuffmerge software to combine and then screen the transcripts from each sample. In this study, a total of 20,438 transcripts were identified, 16,342 of which were mRNAs. In addition, a total of 1,376 lncRNAs had been previously annotated, 1,252 novel lncRNAs were identified (Figure 1A, B), and 1,468 transcripts of uncertain coding potential (TUCPs) were screened. Only two types of lncRNAs were identified: an overwhelming majority of long intergenic noncoding RNAs (lincRNA) (79.7%) and a minority of antisense lncRNAs (20.3%) (Figure 1C). LncRNAs in breast muscle tissue had lower total transcript length, fewer exons, and fewer ORF numbers than mRNAs (Figure 1D-F) and lower average transcript abundance (Figure 1G).

### Characteristics of differentially expressed lncRNAs

To gain insight into the key lncRNAs involved in chicken breast muscle development, we analyzed the differentially expressed lncRNAs (DE-lncRNAs) (|Fold Change, FC| ≥ 1.7, q-value < 0.05) at four different developmental stages, 6 weeks (W6), 14 weeks (W14), 22 weeks (W22) and 30 weeks (W30). Among the six different comparison groups, there were 53, 61, 50, 153, 117, and 78 DE-lncRNAs in the W14 vs. W6, W22 vs. W14, W22 vs. W6, W30 vs. W6, W30 vs. W14, and W30 vs. W22 comparison groups, respectively. Venn diagram analysis shows that there were no common DE-lncRNAs among the six comparison groups (Figure 2). Only LNC_000920 was commonly found in the following five comparison groups: W14 vs. W6, W22 vs. W14, W30 vs. W6, W30 vs. W14, and W30 vs. W22. Moreover, LNC_000255 appeared in the following comparison groups: W14 vs. W6, W22 vs. W14, W22 vs. W6, W30 vs. W6, W30 vs. W14, and W30 vs. W22. Moreover, LNC_000255 appeared in the following comparison groups: W14 vs. W6, W22 vs. W14, W22 vs. W6, W30 vs. W6, W30 vs. W14, and W30 vs. W14. Then, the DE-lncRNAs were identified by a DEGseq (differentially expressed gene, DEG) analysis, and DE-lncRNAs were clustered based on their expression profiles (Figure S1). The clustering results showed that the intragroup repeats of each group were clustered together, indicating that the intragroup differences were smaller than the intergroup differences, which proved that the data were reliable. In addition, we found that 22 weeks clustered close to 14 weeks, followed by 6 weeks, and the farthest distance was from 30 weeks. In addition, we also found that the DE-lncRNAs between W22 and W14 were the least (Figure 2). It is possible that during 14 weeks ~ 22 weeks, many of the same lncRNAs played a common role, which also led to the reduction of DE-lncRNA commonly seen in the six comparison groups.

Moreover, after identifying DE-lncRNAs, we analyzed the chromosome distribution information of the DE-
lncRNAs and found that DE-lncRNAs were distributed in almost all chromosomes but not in chromosomes 22 and 27, and the largest number was found in chromosome 1 (Figure S2). In addition, we selected several lncRNAs for data validation. The lncRNA expression level was determined and showed a similar pattern compared to the RNA-seq data (Figure 3), thus indicating that the RNA-seq data were authentic.

To investigate the possible functions of the DE-lncRNAs in breast muscle between the different developmental stages, we conducted Gene Ontology (GO, http://www.geneontology.org/) enrichment analysis to uncover the enriched biological process terms associated with DE-lncRNAs target DEGs for each comparison group. Only the top 20 GO terms for the W14 vs. W6, W22 vs. W14, and W30 vs. W22 comparison groups are shown in Figure 4 and Figure S3. The cis-targets of all lncRNAs were predicted with a 100 kb upstream and downstream range. The GO enrichment analysis of the cis-targets of lncRNAs showed that only one growth- and development-related GO term called positive regulation of embryonic development, was found in the W22 vs. W14 comparison group (Figure 4A). In addition, we predicted the regulation in trans between lncRNAs and genes by the Pearson correlation coefficient r > 0.95. In the GO analysis of the trans-targets of lncRNAs, we only found several muscle development-related GO terms in the W22 vs. W14 comparison group (Figure 4B), such as positive regulation of skeletal muscle tissue development, positive regulation of striated muscle tissue development, positive regulation of muscle organ development, positive regulation of muscle tissue development, and positive regulation of striated muscle cell differentiation.

To further understand how DE-lncRNA-targeted DEGs play roles in regulating chicken muscle development, we performed Kyoto Encyclopedia of Genes and Genomes (KEGG, http://www.genome.jp/kegg/) pathway analysis for each comparison. In the KEGG pathway analysis of the cis-targets of lncRNAs, the phagosome pathway was identified as the most significantly enriched pathway for the W14 vs. W6 comparison group (Figure S4A). Furthermore, for the W22 vs. W14 comparison group, the endocytosis pathway was identified as the most significantly enriched pathway (Figure S4B). Additionally, the focal adhesion and cytokine-cytokine receptor interaction pathways were the top two pathways for the W30 vs. W22 comparison group (Figure S4C). Moreover, the KEGG pathway analysis of the trans-targets of lncRNAs showed that the propanoate metabolism pathway and fatty acid metabolism pathway were the top two pathways for the W14 vs. W6 comparison group (Figure S4D). In the W22 vs. W14 comparison group, the two top pathways were arginine and proline metabolism and the MAPK signaling pathway (Figure 5A). In addition, for the W30 vs. W22 comparison group, there were two top pathway terms, the MAPK signaling pathway and the regulation of actin cytoskeleton pathway (Figure 5B). We found that the MAPK signaling pathway was one of the most frequently enriched pathways in both the W22 vs. W14 and W30 vs. W22 comparison groups.

**Interactions between lncRNAs and mRNAs during breast muscle development**

To explore how lncRNAs interact with their target genes to regulate chicken muscle development and to identify key molecular players in the process, we first predicted the cis- and trans-targets of DE-lncRNAs
and then constructed the regulatory networks between DE-IncRNAs and their target genes. A total of 13,460 cis-regulatory interaction relationships were detected between 2,309 IncRNAs and 7,783 mRNAs (Table S2). In addition, 13,343 trans-regulatory interaction relationships were detected between 733 IncRNAs and 2,190 mRNAs (Table S3). Moreover, we constructed the IncRNA-mRNA networks of cis- and trans-targets for muscle development related to the top 20 GO terms, including positive regulation of embryonic development, positive regulation of skeletal muscle tissue development, positive regulation of striated muscle tissue development, positive regulation of muscle organ development, positive regulation of muscle tissue development and positive regulation of striated muscle cell differentiation. In the networks of cis-target DEGs of DE-IncRNAs of the muscle development-related GO terms, we found a total of 10 interaction relationships between 3 genes and 10 IncRNAs (Figure 6A). In addition, in the networks of trans-target DEGs of DE-IncRNAs of the muscle development-related GO terms we found 7 interaction networks between 3 genes and 7 IncRNAs (Figure 6B). Furthermore, we also generated the IncRNA-mRNA networks of the frequently enriched MAPK signaling pathway, which had a total of 25 interaction relationships between 11 genes and 25 cis-regulating IncRNAs and 27 interaction relationships between 8 genes and 17 trans-regulating IncRNAs (Figure 6C). Interestingly, we found that the networks contained MEF2C and its targeting IncRNAs (ALDBGALT0000008862, ALDBGALT0000008865, LNC_001247, etc.) were not only in the muscle development-related GO terms but also in the MAPK signaling pathway.

LncRNA-miRNA interactions

In our previous study [19], we found 388 known miRNAs and 31 novel miRNAs. To explore the interactions between lncRNAs and miRNAs, we predicted the target relationship between lncRNAs and miRNAs in different comparison groups (Table S4). Twelve common target DE-miRNAs of DE-IncRNAs were found in different comparison groups. It is important that some of them were muscle-specific miRNAs, such as gga-miR-206, gga-miR-1a-3p, and miR-133a-3p. Only the IncRNAs (FPKM>1) of these miRNA targets are shown in Figure 7. Then, we predicted the pre-miRNAs with homology to lncRNAs. Unexpectedly, the precursors of four newly identified miRNAs were found to be homologous to lncRNAs, and the precursors were temporarily named gga-miR-N1, gga-miR-N2, gga-miR-N3 and gga-miR-N4 (Figure 8, Table S5), for example, the pre-miRNA of gga-miR-N1 exactly matches ALDBGALT0000008009 at its position from 309 to 374, and the pre-miRNA of gga-miR-N2 exactly matches Inc_000010 from 1101 to 1161. These IncRNAs may form miRNA precursors through intracellular shearing and then could be processed to generate specific miRNAs that regulate the expression of target genes.

LncRNA-miRNA-mRNA regulatory networks

To identify potential ceRNA networks in the development of chicken breast muscle, we constructed ceRNA networks of DEGs, differentially expressed miRNAs (DEMs), and DE-IncRNAs (q-value <0.05 and log2|FC|≧1) by Cytoscape (Figure S5), and we found some ceRNA networks associated with muscle development-related GO terms (Figure 9). For example, 445 ceRNA networks were found in the IncRNA-miRNA-mRNA network in the W14 vs. W6 comparison group (Figure S5A). Among these networks, ankyrin
repeat domain 1 (ANKRD7) is related to skeletal muscle cell differentiation, and it was involved in 13 ceRNA networks containing two miRNAs (miR-148a-3p and miR-10b-5p) and 12 IncRNAs (LNC_000846, ALDBGALT0000001052, LNC_000453, LNC_001182, ALDBGALT0000006695, ALDBGALT0000002546, ALDBGALT0000006376, LNC_000255, LNC_000938, ALDBGALT0000006015, LNC_001012, and ALDBGALT000000480) (Figure 9A). In addition, dynein light chain 2 (DYNLL2) is related to the myosin complex GO term, which was involved in 19 ceRNA networks with two miRNAs (gga-miR-148a-3p and gga-miR-130b-3p) and 12 lncRNAs (LNC_000846, ALDBGALT0000001052, LNC_000453, LNC_001182, ALDBGALT0000006695, ALDBGALT0000002546, ALDBGALT0000006376, LNC_000255, LNC_001012, LNC_000938, ALDBGALT0000006015, and ALDBGALT0000003517) (Figure 9A). In the W22 vs. W14 comparison group, there were 76 ceRNA networks (Figure S5B). Among those, myosin heavy polypeptide 11 (MYH11) is related to muscle cell differentiation, which was involved in 8 ceRNA networks containing gga-miR-194 and 8 lncRNAs (LNC_000668, LNC_000569, LNC_001009, ALDBGALT000000938, LNC_001086, LNC_000373, LNC_000920, and LNC_001140) (Figure 9B). Moreover, there were 450 ceRNA networks in the W30 vs. W22 comparison group (Figure S5C). The skeletal muscle fiber development-related genes regulator of calcineurin 1 (RCAN1) and ANKR71 were involved in 8 ceRNA networks containing gga-miR-92-3p and 8 IncRNAs (LNC_000920, LNC_000704, ALDBGALT000001001, ALDBGALT000005521, LNC_000618, ALDBGALT000000349, LNC_000204, and ALDBGALT0000003603) (Figure 9C).

**Protein-Protein Interaction (PPI) network of DE-lncRNA target genes**

The PPI network was constructed by Cytoscape software using the predicted protein-protein interaction networks from the STRING database (Figure 10). The PPI network from DE-lncRNA cis-target genes of the W14 vs. W6 comparison group contained 13 protein-protein pairs, such as IGF-I-EGF. Moreover, in the W22 vs. W14 comparison group, there were 6 protein-protein pairs, for example, FZD6-WNT11. Furthermore, the DEGs from the W30 vs. W22 comparison group included 23 protein-protein pairs, including AR-PPAR, etc. However, no PPI network was found in the DE-lncRNA trans-target genes of the W14 vs. W6 and W22 vs. W14 comparison groups. In addition, the DE-lncRNA trans-target genes from the W30 vs. W22 comparison group included 36 protein-protein pairs, including CDK8-CCNC, etc.

**Discussion**

The growth and development of skeletal muscle is regulated by many factors, such as nutrition, genetics, and environment. In genetics research, previous studies focused on the role of protein-coding genes in skeletal muscle growth and development, and later it was found that non-coding RNA represents the majority of the transcriptome, with studies showing that only < 2% of mammalian genomes encode proteins [20]. The existence of a large number of non-coding RNAs must have value and significance. Non-coding RNAs, including miRNAs [21], IncRNAs [22, 23], circRNAs [24], etc., play different roles in complex biological processes. However, there are few studies on IncRNAs in chicken skeletal muscle development. In our study, we compared the differences in IncRNA expression in chicken breast muscles...
of chickens at four different ages (6 weeks, 14 weeks, 22 weeks, and 30 weeks) to identify important IncRNAs associated with muscle development.

Our research showed that chromosomal distribution of DE-IncRNAs was mainly concentrated in chromosome 1, which was similar to previous studies, that is, there were more IncRNAs distributed in larger chromosomes [25]. The DE-IncRNAs on these chromosomes may exert their effects by regulating the expression of adjacent functional genes. Recent studies have demonstrated that IncRNAs can control the expression of important genes through cis- and trans-regulatory mechanisms [26]. In the present study, functional enrichment analyses of both cis- and trans-target genes of DE-IncRNAs revealed that the muscle development-related enriched GO terms were only found in the W22 vs. W14 comparison group. This is consistent with our previous transcriptomics analysis [19], and indicates that 14~22 weeks is an important stage in the development of chicken breast muscle. In addition, in the pathway enrichment analysis of the DE-IncRNA trans-target genes, it was found that there was a common pathway in the W22 vs. W14 and W30 vs. W22 comparison groups, the MAPK signaling pathway. The MAPK family plays crucial roles in complex cellular processes such as proliferation, differentiation, and development by regulating the cell cycle and other cell proliferation-associated proteins [27]. We speculate that the DE-IncRNAs in the W22 vs. W14 and W30 vs. W22 comparison groups may play important roles in regulating muscle cell proliferation. Moreover, the function of IncRNAs can be inferred from associated contiguous or co-expressed protein-coding genes [28]. Thus, we constructed interaction networks of DE-IncRNAs and their cis- and trans-target genes, and only some of the genes associated with muscle development-related GO terms and the MAPK signaling pathway and their corresponding IncRNAs are shown in Figure 6. Interestingly, we found that the networks containing MEF2C and its targeting IncRNAs were not only in the muscle development-related GO terms but also in the MAPK signaling pathway. Research has shown that MEF2 factors are involved in muscle differentiation, and MyoD and MEF2 family members interact to activate transcription and myogenesis [29]. Thus, we speculate that these IncRNAs, such as ALDBGALT0000008862, ALDBGALT0000008865, and LNC_001247, are involved in muscle differentiation.

LncRNAs have significant similarities to classic mRNAs during transcription, so miRNAs can not only target mRNAs but also regulate target IncRNAs and reduce their structural and functional stability [30]. It has been speculated that miRNA-192 and miRNA-204 directly suppress IncRNA HOTTIP and interrupt GLS1-mediated glutaminolysis in hepatocellular carcinoma [31]. Interestingly, miRNAs can also enhance IncRNA expression through a number of mechanisms [32]. miR-140 binding sites were identified in NEAT1, and the authors found that mature miR-140 could physically interact with NEAT1 in the nucleus, thereby promoting the expression of NEAT1 [33]. The predicted miRNA-IncRNA networks are shown in Figure 7 and suggest that miRNAs may play a role in promoting or inhibiting IncRNA expression. Interestingly, several muscle-specific miRNAs, such as gga-miR-206, gga-miR-1a-3p, and miR-133a-3p have been identified [34]. Therefore, we speculate that the target IncRNAs of these miRNAs may also be involved in the muscle development process. In addition, IncRNAs play many complex functions in gene expression and signal transduction and can also be used as precursors of miRNAs. LncRNAs can produce specific miRNAs through intracellular RNA splicing to affect the posttranscriptional regulation of
mRNAs. It has been found that the H19 RNA is a miRNA precursor and generates the exonic microRNA miR-675 [35]. In this study, we found 5 pairs of homologous lncRNAs and pre-miRNAs, including ALDBGAL0000008009 with gga-miR-N1 and lnc_000010 and lnc_000011 with gga-miR-N2. We believe that the miRNAs produced by these lncRNAs play a functional role.

There is increasing evidence that supports the ceRNA hypothesis that lncRNAs regulate target genes by competitively adsorbing miRNAs [36]. For instance, lncRNA-Unigene56159 can directly bind to miR-140-5p and act as a ceRNA of miR-140-5p to regulate the expression of its target gene Slug, thereby affecting HCC cell migration and invasion [37]. Furthermore, lncRNA-MEG3 acts as a tumor suppressor and a ceRNA that regulates E-cadherin and forkhead box O1 (FOXO1) expression by competitively binding to miR-9 [38]. In thyroid cancer, lncRNA-Gas5 regulates gene of phosphate and tension homology deleted on chromosome ten (PTEN) expression through a ceRNA mechanism as a sponge for miR-222-3p [39]. To fully identify how lncRNA-associated ceRNA networks affect breast muscle development in different developmental stages, we predicted and successfully constructed a network of ceRNAs associated with DE-lncRNAs in different comparison groups. For example, in the W14 vs. W6 comparison group, there were ceRNA networks containing the DYNLL2 gene with 12 lncRNAs that targeted 2 miRNAs, gga-miR-148a-3p and gga-miR-130b-3p (Figure 9A). DYNLL2 is involved in a variety of cellular processes and interacts with myosin 5a (myo5a) to participate in cargo transport [40]. Therefore, we speculate that the above 12 lncRNAs may regulate DYNLL2 by adsorbing miR-148a-3p and gga-miR-130b-3 to regulate muscle development. Furthermore, the ceRNA network analysis showed that ANKRD1 is involved in 13 ceRNA networks containing two miRNAs (miR-148a-3p and miR-10b-5p) and 12 lncRNAs in the W14 vs. W6 comparison group (Figure 9A). Moreover, ANKRD1 was involved in 8 ceRNA networks containing gga-miR-92-3p with 8 lncRNAs in the W30 vs. W22 comparison group (Figure 9C). Studies have shown that ANKRD1 can induce gene expression in cultured skeletal muscle cells and trigger signaling via myogenic regulators (MRFs) during myogenesis [41]. Therefore, we think that the above 20 lncRNAs can also play roles in skeletal muscle cells to regulate the ANKRD1 gene by adsorbing miR-148a-3p, miR-10b-5p, and gga-miR-126-5p.

In addition, we also demonstrated the interactions between DE-lncRNA target genes in Gushi chicken breast development. The interaction between IGF-I and epidermal growth factor (EGF) was identified in the W14 vs. W6 comparison group. It has been reported that the expression of the IGF gene is enhanced during muscle hypertrophy and that locally produced IGF-I may play roles in skeletal muscle growth [42]. Heparin-binding epidermal growth factor (HB-EGF) promotes airway smooth muscle (ASM) cell proliferation through the MAPK pathway [43]. Thus, we surmise that IGF-I and EGF can interact to play a role in skeletal muscle cell proliferation. Moreover, the PPI networks based on the W22 vs. W14 comparison group included FZD6-WNT11 among others. The WNT/planar cell polarity (PCP) signaling pathway is involved in the development of human cancer. In this signaling pathway, winglesstype MMTV integration site family 11 (WNT11) can transduce PCP signals through receptors such as frizzled homolog 6 (FZD6) [44]. Thus, we speculate that FZD6 and WNT11 can interact to play a role in cell proliferation. In addition, some of the DE-lncRNA trans-targets from the W30 vs. W22 comparison group were including the CDK8-CCNC PPI network. Research has shown that cyclin-dependent kinase 8 (CDK8)
and cyclin C (CCNC) are transcriptional regulators that mediate several oncogenic pathways [45]. Therefore, the interactions between these genes may eventually affect muscle development, and the above results indicate that there are complex intergenic interactions in the development of chicken breast muscle.

Conclusions

In conclusion, we first described the lncRNA profile of Gushi chicken breast muscle development at 6, 14, 22, and 30 weeks. In the W22 vs. W14 comparison groups, some GO terms related to muscle development were found, further indicating that between 14 and 22 weeks, changes in the expression of some crucial lncRNAs and their target genes affected the growth and development of chicken breast muscles during these important stages. In addition, the MAPK signaling pathway has been found to play a vital role in muscle development. MEF2C and its target lncRNA, such as ALDBGALT0000008862, ALDBGALT0000008865, and LNC_001247 may be involved in muscle regulation through the MAPK signaling pathway. These results provide insight and valuable resources for further research on the molecular mechanism of skeletal muscle development after hatching.

Methods

Animals and samples preparation

The experimental animals were Gushi chickens which from the Animal Center of Henan Agricultural University in this study. A total of 300 one-day-old female Gushi chickens were raised in cages of the same environment with standard conditions for pure breeding conservation of Gushi chickens. In this study, three healthy chickens were randomly selected at 6 weeks, 14 weeks, 22 weeks, and 30 weeks of age, respectively. Therefore, twelve chickens were used in this study, our sample size is sufficient, and the remaining healthy chickens are still used for the pure breeding conservation of Gushi chickens. These chickens were fed a two-stage feeding in which 18.5% crude protein and 12.35 MJ/kg were prepared in the first stage (younger than 14 weeks) and 15.6% crude protein and 12.75 MJ/kg in the second stage (older than 14 weeks), and chickens had free access to water. Chickens were anesthetized by intravenous injection of sodium pentobarbital (40 mg/kg) at a concentration of 0.2% in the wing vein. Under deep anesthesia, these individuals were euthanized by intravenous KCL (1-2 mg/kg). The left breast muscle tissue was then collected and immediately frozen in liquid nitrogen and stored at -80°C until RNA extraction.

Illumina deep sequencing and sequence analysis

Twelve RNA libraries were constructed using 12 breast muscle samples (W6, W14, W22, and W30; each stage had three individual samples). Total RNA was isolated from breast muscle samples using TRIZol reagent (Invitrogen, Carlsbad, CA, USA) following the manufacturer's instructions. The quantity and quality of RNA were evaluated by NanoDrop 2000 (Thermo Scientific, Wilmington, DE, USA) and by 1%
agarose gel electrophoresis. A total of 3 µg RNA per sample was used as input material for the cDNA library. First, the Epicentre Ribo-zero™ rRNA Removal Kit (Epicentre, Madison, Wisconsin, USA) was used to remove ribosomal RNA. Second, sequencing libraries were generated using rRNA-depleted RNA with the NEBNext® Ultra™ Directional RNA Library Prep Kit for Illumina® (NEB, Ipswich, MA, USA) following the manufacturer’s instructions. The products were then purified using a TruSeq RNASample Prep Kit v2 (New England Biolabs, Ipswich, MA, USA), and library quality was assessed on an Agilent Bioanalyzer 2100 system (Agilent Technologies, CA, USA). Finally, the libraries were sequenced using an Illumina HiSeq 2500 platform, and paired-end reads were generated. The raw data in the fastq format were first processed by in-house scripts. The Illumina sequencing raw reads were obtained by removing adapter sequences, reads with poly-N and low-quality reads, in which the number of bases with a quality value Q ≤ 20 was >50%. All downstream analyses were based on high-quality clean data. Reference genome and gene model annotation files were downloaded from a genome website (ftp://ftp.ensembl.org/pub/release-83/fasta/gallus_gallus /dna/). An index of the reference genome was built using Bowtie v2.2.3, and paired-end clean reads were aligned to the reference genome using TopHat v2.0.12. The Cufflinks v2.1.1 Reference Annotation Based Transcript (RABT) assembly method was used to construct and identify transcripts from the TopHat alignment results.

Identification of lncRNAs

The combined transcript sets were screened for lncRNAs, and the lncRNA screening process was divided into the following five steps: the first step was to select the transcripts with exon number ≥ 2; the second step was to select the transcripts with transcript length > 200 bp; the third step was to use Cuffcompare software to filter out the transcripts that overlapped with exon regions annotated in the database, and the lncRNAs in the database that overlapped with the exon regions of splicing transcripts were annotated as lncRNAs in subsequent analyses; the fourth step was to calculate the expression of each transcript by Cuffquant, whereby transcripts with FPKM (fragments per kilobase of exons per million mapped fragments) ≥ 0.5 expression level were selected; and the fifth step was to screen the protein coding potential, in which the four databases CPC, PFAM, PhyloCSF and CNCI were used to remove potential protein coding transcripts. In this study, the resulting transcripts with no protein coding potential in the software analyses resulted in the lncRNA dataset, and the transcripts that were predicted to have protein coding potential by at least one coding potential prediction software were set as TUCPs.

Differential expression analysis

Cuffdiff (v2.1.1) was used to calculate the FPKM of lncRNAs in each sample, and cuffdiff used a model based on a negative binomial distribution to provide statistical procedures for determining differential expression in digital transcript or gene expression data [46]. Based on Illumina sequencing data, FPKM values were used to assess the expression levels of lncRNAs in the libraries constructed from breast muscle. The FC for each lncRNA between two discretionary stages was calculated according to comparisons among four comparison groups (W6, W14, W22, and W30). Differential expression analysis
among the four groups was performed using the DESeq R package (1.8.3), and lncRNAs and genes found by DESeq with q-value < 0.05 and |FC|≥1.7 were considered to be differentially expressed.

**Cis- and trans-targeting analyses**

Differentially expressed lncRNAs were selected for cis- and trans-target gene predictions and were integrated with differentially expressed gene data to improve the veracity of target prediction. In the present study, DEGs located ∼100 kb upstream and downstream of DE-lncRNAs were classified as cis-acting target genes. In addition, we predicted the regulation in trans between lncRNAs and genes by the Pearson correlation coefficient, r > 0.95. The relationship between lncRNAs and their target genes was demonstrated by Cytoscape 3.4 (http://www.cytoscape.org/).

All potential target genes for DE-lncRNAs in each comparison group were used in bioinformatics analysis. GO and KEGG pathway analyses were conducted using the DAVID database [47] to visualize data. Only GO terms and KEGG pathways with corrected p-values (t-test) < 0.05 were considered significantly enriched.

The data including mRNAs [3] and miRNAs [19] obtained from our previous study were used for integrative analysis with the lncRNA data. The transcriptome and small RNA library were constructed using the same tissue RNA Gushi chicken breast muscle samples from chickens at the four developmental stages in our past research. Additionally, q-value < 0.05 was set as the threshold for significant DEMs by default. DEMs, DEGs, and DE-lncRNAs were used to construct lncRNA-miRNA-mRNA interaction networks by Cytoscape 3.4. PPI analysis of DEGs targeted by DE-lncRNAs was based on the STRING database (https://string-db.org, Organism: Gallus gallus). The network of interactions between these DEGs was generated in the STRING database and imported into Cytoscape software for visualization; scores >700 were selected as significant interactions to display.

**Quantitative real-time PCR (qRT-PCR) analysis**

The qRT-PCR analysis of lncRNAs was performed using the PrimeScript™ RT reagent Kit (TaKaRa, Dalian, China) according to the manufacturer's instructions. qRT-PCR was performed with a LightCycler® 96 instrument qRT-PCR system (Roche, Basel, Switzerland) with the PrimeScript™ RT Reagent Kit with gDNA Eraser (Takara, Kyoto, Japan). The amplification program consisted of 95°C for 3 min; 40 cycles of 95°C for 10 s, annealing at 60°C for 30 s, and 72°C for 30 s; and 72°C for 10 min. The relative expression levels were analyzed with the $2^{-\Delta\Delta Ct}$ method. The qRT-PCR primer sequences are listed in Table S6.

**Statistical analysis**

The qRT-PCR quantitative expression data and graphs were generated in GraphPad Prism (version 5.0) software (San Diego, CA, USA). Statistical significance of the qRT-PCR quantitative expression data was tested by performing two-tailed unpaired t-tests [48]. Data are presented as the means containing three replicates.
Abbreviations

GHSR: growth hormone secretagogue receptor; IGFs: insulin-like growth factors; TGFβ2: transforming growth factor beta 2; MEF2B: myocyte enhancer factor 2B; IncRNAs: long noncoding RNAs; MyoD: myogenic differentiation antigen; IRS1: insulin receptor substrate 1; TUCPs: transcripts of uncertain coding potential; lncRNA: long intergenic noncoding RNAs; DE-IncRNAs: differentially expressed IncRNAs; W6: 6 weeks; DEG: differentially expressed gene; GO: Gene Ontology; KEGG: Kyoto Encyclopedia of Genes and Genomes; DEMs: differentially expressed miRNAs; ANKRD1: ankyrin repeat domain 1; DYNLL2: dynein light chain 2; MYH11: myosin heavy polypeptide 11; RCAN1: regulator of calcineurin 1; FOXO1: forkhead box O1; PTEN: phosphate and tension homology deleted on chromosome ten; MRFs: myogenic regulators; EGF: epidermal growth factor; HB-EGF: Heparin-binding epidermal growth factor; ASM: airway smooth muscle; PCP: planar cell polarity; WNT11: wingless-type MMTV integration site family 11; FZD6: frizzled homolog 6; CDK8: cyclin-dependent kinase 8; CCNC: cyclin C.

Declarations

Ethics approval and consent to participate

The experiments and animal care were performed according to the Regulations for the Administration of Affairs Concerning Experimental Animals (Ministry of Science and Technology, China, 2004). The protocols were approved by the Institutional Animal Care and Use Committee of Henan Agricultural University, China. In this study, written informed consent was obtained from Henan Agricultural University to use these animals.

Consent for publication

Not applicable.

Availability of data and materials

All raw sequences have been deposited in the NCBI database Sequence Read Archive with the accession numbers PRJNA516810 (mRNA and IncRNA) and PRJNA516961 (miRNA).

Competing interests

The authors declare that they have no competing interests.

Funding

This work was supported by grants from the National Natural Science Foundation of China (31572356), the Key Scientific Research Projects of Henan Colleges and Universities (15A230003), the Program for Innovation Research Team of Ministry of Education (IRT16R23) and NSFC-Henan joint grant (U1804107)
and Scientific Studio of Zhongyuan Scholars (30601985). The funding bodies had no role in study design or in any aspect of the collection, analysis and interpretation of data or in writing the manuscript.

**Author Contributions**

YL performed the data analysis and wrote the main manuscript; WJ, BZ helped to revise the manuscript; YC, WJ and BZ performed the experiments and analysis data; GL reviewed and edited the manuscript; YZ and YG performed the statistical analysis; GS and RH helped to draft the manuscript; ZL and HL analyzed the partial sequencing data; YT and XL co-designed the research; XK coordinated the research; GL and XK provide the materials. All authors have read and agreed to the published version of the manuscript.

Interaction network between 12 common DE-miRNAs and their target IncRNAs of different comparison groups.
Figure 8

Homology of lncRNAs with pre-miRNAs. (A) Homology of ALDBGALT0000008009 with gga-miR-N1. (B) Homology of lnc_000010 and lnc_000011 with gga-miR-N2. (C) Homology of lnc_000205 with gga-miR-N3. (D) Homology of lnc_000950 with gga-miR-N4.

Figure 9

The lncRNA-miRNA-mRNA ceRNA networks of muscle development-related GO terms. (A) W14 vs. W6 comparison group; (B) W22 vs. W14 comparison group; (C) W30 vs. W22 comparison group.
Figure 10

The PPI network of DE-IncRNA target genes. (A) Cis-target genes of the W14 vs. W6 comparison group; (B) Cis-target genes of the W22 vs. W14 comparison group; (C) Cis-target genes of the W30 vs. W22 comparison group; (D) Trans-target genes of the W30 vs. W22 comparison group.
