Discrete Morse Theory for Computing Zigzag Persistence

Clément Maria ∗  Hannah Schreiber †

July 16, 2018

Abstract

We introduce a theoretical and computational framework to use discrete Morse theory as an efficient preprocessing in order to compute zigzag persistent homology.

From a zigzag filtration of complexes \((X_i)\), we introduce a zigzag Morse filtration whose complexes \((A_i)\) are Morse reductions of the original complexes \((X_i)\), and we prove that they both have same persistent homology. This zigzag Morse filtration generalizes the filtered Morse complex of Mischaikow and Nanda [34], defined for standard persistence.

The maps in the zigzag Morse filtration are forward and backward inclusions, as is standard in zigzag persistence, as well as a new type of map inducing non trivial changes in the boundary operator of the Morse complex. We study in details this last map, and design algorithms to compute the update both at the complex level and at the homology matrix level when computing zigzag persistence. We deduce an algorithm to compute the zigzag persistence of a filtration that depends mostly on the number of critical cells of the complexes, and show experimentally that it performs better in practice.

1 Introduction

Persistent homology is an algebraic method that permits to characterize the evolution of the topology of a changing space. The theory has found many applications, especially in data analysis where it has been successfully applied to material science [28], shape classification [8, 12], or clustering [11, 14]. More specifically, persistent homology studies the topology of filtrations, i.e., growing sequences of spaces \(X_i\):

\[
X_1 \subseteq X_2 \subseteq \cdots \subseteq X_n
\]  

(1)

Applying a homology functor, for a coefficient field \(\mathbb{F}\), to a filtration leads to a sequence of vector spaces — the homology groups \(H(X_i, \mathbb{F})\) — connected by maps induced by the inclusions, known as a persistence module:

\[
H(X_1, \mathbb{F}) \longrightarrow H(X_2, \mathbb{F}) \longrightarrow \cdots \longrightarrow H(X_{n-1}, \mathbb{F}) \longrightarrow H(X_n, \mathbb{F})
\]  

(2)

Computing the persistent homology of a filtration \((1)\) consists of computing the isomorphism type, known as the interval decomposition, of its corresponding persistence module \((2)\).

The success of persistent homology relies on sound theoretical foundations [23, 24, 38], favorable stability properties [5, 13, 17], and fast algorithms, both theoretically [16, 18, 21, 33] and experimentally [2, 3, 7, 15], to compute the interval decomposition of an input filtration. This last effort towards better implementations has led to dramatic improvements of running times in practice, and the emergence of efficient software libraries in the field, such as Dionysus [35], DIPHA [4], GUDHI [30], and Ripser [1].

Another approach to fast computation consists of preprocessing the input filtration \((1)\) in order to drastically reduce the size of the domains \(X_i\), while preserving the interval decomposition of the

In computational topology, an \( F \) node of the map being the same as that of the arrow. We denote such a representation by

\[
\begin{array}{c}
\phi_i : X_i \rightarrow X_{i+1}
\end{array}
\]

where, by convention in this article, bidirectional arrows are either forward or backward.

Zigzag persistent homology is a generalization of persistent homology that allows the measurement and tracking of the topology of spaces that both grow and shrink, known as a zigzag filtration:

\[
X_1 \xleftarrow{f_1} X_2 \xrightarrow{g_1} \cdots \xleftarrow{f_{n-1}} X_{n-1} \xrightarrow{g_n} X_n
\]

which gives a zigzag module, also admitting an interval decomposition:

\[
H(X_1, F) \longrightarrow H(X_2, F) \longrightarrow \cdots \longrightarrow H(X_{n-1}, F) \longrightarrow H(X_n, F)
\]

The theory of zigzag persistence was introduced in [9], and theoretical [33] and practical [10, 32] algorithms have been introduced to compute it. Zigzag persistence has great applicative potential, considering it provably produces better topological information in topology inference [37], while maintaining the homology of smaller spaces \( X_i \) thanks to deletions of faces, and more generally allows a finer approach to data analysis, such as density estimation and topological bootstrapping [9].

However, computing zigzag persistence is more intricate than computing persistent homology, essentially due to the fact that the full sequence of insertions and deletions of faces is unknown, which requires the maintenance and update of heavier data structures. As a consequence, none of the optimizations of persistence algorithms mentioned above adapt to the zigzag case. The relatively poor performance of zigzag persistence implementations, compared with persistent homology ones, is a major hindrance to its practical use.

Contributions. In the spirit of [34], we introduce a preprocessing reduction of a zigzag filtration [4] based on discrete Morse theory [25]. After introducing the necessary background in Section 2 we introduce in Section 3 a zigzag Morse filtration that generalizes the filtered Morse complex [34] of standard persistence, and we prove that it has same persistent homology as the input zigzag filtration. Because of removal of cells not agreeing with the Morse decomposition, the zigzag Morse filtration contains chain maps that are not inclusions. We study the effect of those maps on the boundary operator of the Morse complex in Section 4 and design a persistence algorithm for zigzag Morse complexes in Section 5 taking this new chain map into account. Finally, we study the experimental performance of the zigzag persistence algorithm for Morse complexes in Section 6.

2 Background

Quiver theory. Throughout this article, we fix a field \((F, +, \cdot)\). An \( A_n \)-type quiver \( Q \) is a directed graph:

\[
\bullet_1 \xleftarrow{f_1} \bullet_2 \xrightarrow{g_1} \cdots \xleftarrow{f_{n-1}} \bullet_{n-1} \xrightarrow{g_n} \bullet_n
\]

where, by convention in this article, bidirectional arrows are either forward or backward.

An \( F \)-representation of \( Q \) is an assignment of a finite dimensional \( F \)-vector space \( V_i \) for every node \( \bullet_i \), and an assignment of a linear map \( f_i : V_i \leftrightarrow V_{i+1} \) for every arrow \( \bullet_i \leftrightarrow \bullet_{i+1} \), the orientation of the map being the same as that of the arrow. We denote such a representation by \( \mathcal{V} = (V_i, f_i) \).

In computational topology, an \( F \)-representation of an \( A_n \)-type quiver is called a zigzag module.

Let \( \mathcal{V} = (V_i, f_i) \) and \( \mathcal{W} = (W_i, g_i) \) be two \( F \)-representations of a same quiver \( Q \). A morphism of representations \( \phi : \mathcal{V} \rightarrow \mathcal{W} \) is a set of linear maps \( \{\phi_i : V_i \rightarrow W_i\}_{i=1,\ldots,n} \) such that the diagram on the right commutes for every arrow of \( Q \). The morphism is called an isomorphism (denoted by \( \cong \)) if every \( \phi_i \) is bijective.

The direct sum of two \( F \)-representations \( \mathcal{V} = (V_i, f_i) \), \( \mathcal{W} = (W_i, g_i) \), denoted by \( \mathcal{V} \oplus \mathcal{W} \), is the representation of \( Q \) with space \( V_i \oplus W_i \) for every node \( \bullet_i \), and with map \( f_i \oplus g_i = \begin{pmatrix} f_i & 0 \\ 0 & g_i \end{pmatrix} \) for every arrow \( \bullet_i \leftrightarrow \bullet_{i+1} \). An \( F \)-representation \( \mathcal{V} \) is decomposable if it can be written as the direct sum of two non-trivial representations. It is otherwise said to be indecomposable.
Finally, for any \(1 \leq b \leq d \leq n\), define the interval representation \(\mathbb{I}[b; d]\) as follows:

\[
\begin{array}{cccccccc}
0 & 0 & \cdots & 0 & 0 & 0 & F & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\
[1,b-1] & \{b,d\} & \{d+1,n\}
\end{array}
\]

where the maps 0 and 1 stand respectively for the null map and the identity map.

Theorem 1 states that every representation of an \(A_n\)-type quiver can be decomposed into interval representations, which are the indecomposables for that quiver:

**Theorem 1.** (Krull-Remak-Schmidt, Gabriel). Every \(F\)-representation \(\mathbb{V}\) of an \(A_n\)-type quiver can be decomposed as a direct sum of indecomposables: \(\mathbb{V} \cong \mathbb{V}^1 \oplus \mathbb{V}^2 \oplus \cdots \oplus \mathbb{V}^N\), where each indecomposable \(\mathbb{V}^j\) is isomorphic to some interval representation \(\mathbb{I}[b_j; d_j]\). This decomposition is unique up to permutation of the indecomposables.

In computational topology, such algebraic decomposition of a zigzag module is called an interval decomposition.

**Complexes and homology.** We refer the reader to [23] for an introduction to general abstract complexes and their homology, and to [23] for an introduction to persistent homology.

An abstract complex over a principal ideal domain \(R\) is a graded finite collection \(X = \bigsqcup_{d \in \mathbb{Z}} X_d\) of elements, called cells or faces, together with an incidence function \([\cdot: \cdot] : X \times X \to R\). The dimension of a cell \(\sigma \subseteq X_d\) is \(\dim \sigma = d\). The incidence function satisfies, for any cells \(\sigma, \tau, \mu\):

\[
[\sigma : \tau]^X \neq 0 \Rightarrow \dim \sigma = \dim \tau + 1, \quad \text{and} \quad \sum_{\tau \in X} [\sigma : \tau]^X \cdot [\tau : \mu]^X = 0
\]

If \([\sigma : \tau]^X \neq 0\), we call \(\tau\) a facet of \(\sigma\), and \(\sigma\) a cofacet of \(\tau\). If a cell has no cofacet, it is called maximal.

Standard examples of complexes are simplicial complexes and cubical complexes, with an orientation fixed on their cells. In this case, the principal ideal domain \(R\) is the ring of integers \(\mathbb{Z}\), and incidence function takes values in \(\{-1, 0, 1\} \subset \mathbb{Z}\). In this work, we consider general complexes because they appear under the form of Morse complexes, defined later.

For a field of coefficients \(F\), we associate to a complex \((X, [\cdot: \cdot]^X)\) a chain complex \(C(X, F) = \bigoplus_d C_d(X, F)\), where \(C_d(X, F)\) is the \(F\)-vector space freely generated by the \(d\)-dimensional cells \(X_d\) of \(X\). For every dimension \(d\), the boundary operator \(\partial_d^X : C_d(X) \to C_{d-1}(X)\) is generated by:

\[
\partial_d^X \sigma = \sum_{\tau \in X_{d-1}} [\sigma : \tau]^X \cdot \tau
\]

The \(d\)-cycles and \(d\)-boundaries are respectively \(Z_d(X, F) = \ker \partial_d^X\) and \(B_d(X, F) = \im \partial_{d+1}\), and the \(d\)th homology group is the quotient

\[
H_d(X, F) = Z_d(X, F)/B_d(X, F)
\]

In order to simplify notations, we fix the field \(F\) for the rest of the article, and remove it from notations. To put emphasis on the boundary operator, we denote a complex by \((X, \partial)\), where \(\partial : C(X) \to C(X)\) is \(\partial = \bigoplus_d \partial_d^X\). We avoid the superscript \(\partial^X\) when possible.

We denote by \(\langle \cdot, \cdot \rangle : C(X) \times C(X) \to F\) the inner product on \(C(X)\) making the canonical basis of cells \(\{\sigma\}_{\sigma \in X}\) orthonormal. In particular, \(\langle \partial \sigma, \tau \rangle = [\sigma : \tau]^X\) in \((X, \partial)\). For a chain \(c \in C(X)\), we say that \(c\) contains a cell \(\sigma\), and write \(\sigma \in c\), if \(\langle c, \sigma \rangle \neq 0\).

**Definition 1.** Let \(X\) and \(X'\) be two complexes; \(X\) is included in \(X'\) if \(X \subseteq X'\) as sets of cells, and \([\cdot: \cdot]^X\) \(\big|_X = [\cdot: \cdot]^X\). We also denote the inclusion of complexes by \(X \subseteq X'\).

A standard filtration is a collection of complexes with inclusion relation as pictured in Diagram 3. A zigzag filtration is a collection of complexes with inclusion relations, as pictured in Diagram 4.
Finally, a chain map \( \psi: C(X) \to C(X') \) is a map that commutes with the boundary operators of \( X \) and \( X' \). It induces a morphism \( \psi_*: H(X) \to H(X') \) of homology groups.

**Notations 1.** Let \( X, X', Y, Y' \) be complexes, such that \( X \subseteq X' \) and \( Y \subseteq Y' \), and let \( \phi: C(X) \to C(Y) \) and \( \phi': C(X') \to C(Y') \) be chain maps. If the square on the right commutes, we allow ourselves to use the same notation \( \phi \) for both \( \phi \) and \( \phi' \), when there is no ambiguity on their domain and codomain.

\[
\begin{array}{ccc}
C(X) & \xrightarrow{\phi} & C(Y) \\
\downarrow & & \downarrow \\
C(X') & \xrightarrow{\phi'} & C(Y')
\end{array}
\]

**Discrete Morse theory.** We refer the reader to [25] for an introduction to discrete Morse theory, and to [34] for its application in persistent homology. We follow the general presentation of [34].

The incidence function of a complex induces a face partial ordering \( \prec \) on \( X \) by taking the transitive closure of the relation \( \prec \) defined by

\[
\tau \prec \sigma \iff [\sigma: \tau]^X \neq 0
\]

A partial matching of \( X \) is a partition \( X = A \sqcup Q \sqcup K \) of the cells of the complex, together with a bijective pairing \( Q \leftrightarrow K \), such that if \( (\tau, \sigma) \in Q \times K \) are paired, then \( \dim \sigma = \dim \tau + 1 \), and \( [\sigma: \tau]^X \neq 0 \) is a unit in \( \mathbb{R} \) (e.g., 1 or \(-1\) if \( \mathbb{R} = \mathbb{Z} \)). We call such pair of cells a Morse pair. We denote the bijection \( \omega: Q \to K \), such that Morse pairs are of the form \((\tau, \omega(\tau))\).

Call \( \mathcal{H} \) the oriented Hasse diagram of \((X, \prec)\) where arrows are oriented downwards (i.e., from higher to lower dimensions), except for the arrows between cells of Morse pairs \((\tau, \sigma) \in Q \times K \), oriented upwards. A gradient path between a \( d+1 \)-dimensional cell \( \nu \) and a \( d \)-dimensional cell \( \mu \) is a directed path in \( \mathcal{H} \) from \( \nu \) to \( \mu \) alternating between \( d \) and \( d+1 \)-dimensional cells.

A Morse matching is a partial matching where all gradient paths are acyclic. We denote a Morse matching with a partition \( A \sqcup Q \sqcup K \) and pairing \( \omega: Q \to K \) by \((A, Q, K, \omega)\). Note that a Morse matching can also be defined on a subset \( \Sigma \) of cells of a complex \( X \).

Every gradient path \( \gamma \) is consequently of the form

\[
\gamma = \nu \xrightarrow{\tau_1} \omega(\tau_1) \xrightarrow{\tau_2} \omega(\tau_2) \ldots \xrightarrow{\tau_r} \omega(\tau_r) \xrightarrow{\tau_r} \mu \quad \text{dim} \, d + 1 \quad \text{dim} \, d
\]

We denote by \( \Gamma(\nu, \mu) \) the set of all distinct gradient paths from \( \nu \) to \( \mu \), and we define for every path \( \gamma \) (with the notations of Diagram [3]) its multiplicity \( m(\gamma) \)

\[
m(\gamma) := [\nu: \tau_1]^X \cdot (-1)^{r-1} \prod_{i=1}^{r} \left( [\omega(\tau_i): \tau_i]^X \right)^{-1} \cdot \prod_{i=1}^{r-1} [\omega(\tau_i): \tau_{i+1}]^X \cdot [\omega(\tau_r): \mu]^X
\]

and \( m(\gamma) = [\nu: \mu]^X \) for the one-edge path \( \gamma = (\nu, \mu) \), if it exists. In other words, the multiplicity is the product of incidences for downward arrows, times the product of minus the inverse of incidences for upward arrows in the path.

Given a complex \( X \) and a Morse matching \((A, Q, K, \omega)\), the Morse complex \((A, \partial^A)\) associated to the matching is the complex based on the cells of \( A \), called the critical cells, with incidence function \([ \cdot: \cdot]^A: A \times A \to \mathbb{R}\) defined, for two critical cells \( \nu, \mu \in A \), by

\[
[\nu: \mu]^A := \sum_{\gamma \in \Gamma(\nu, \mu)} m(\gamma)
\]

The dimension of a critical cell \( \sigma \in A \) is the same as the dimension of \( \sigma \) in the original complex \( X \). We denote the set of \( d \)-dimensional cells of \( A \) by \( A_d \). As a complex, the boundary operator of \( A \) is defined, for \( \sigma \in A_d \) a critical cell of dimension \( d \), by

\[
\partial^A_d : A_d \to A_{d-1} \quad \text{such that} \quad \partial^A_d \tau = \sum_{\mu \in A_{d-1}} [\nu: \mu]^A \cdot \mu
\]

\footnote{Note that our definition differs from the original reference [25], where gradient paths connect cells of same dimension.}
By a small abuse of notation, we refer to $X$ and $A$ as chain complexes and write $H(X)$ and $H(A)$ for their homology, provided there is no ambiguity in the definition of their incidence function and boundary maps.

We finally have the fundamental theorem of discrete Morse theory,

**Theorem 2** (Forman [25]). A complex $(X, \partial X)$ and its Morse complex $(A, \partial A)$, for a Morse matching $(A, Q, K, \omega)$ of $X$, have isomorphic homology groups.

**Persistent homology and discrete Morse theory.** We refer the reader to [34] for the study of the (standard) persistent homology of discrete Morse complexes.

As mentioned in the introduction, persistent homology is the study of persistent modules induced by filtrations. Let $X_1 \subseteq \ldots \subseteq X_n$ be a filtration of complexes. A **standard Morse filtration** (called filtered Morse complex in [34]) for this filtration is a collection of Morse matching $(A_i, Q_i, K_i, \omega_i)_{i=1,\ldots,n}$ for each $X_i$, satisfying

$$A_i \subseteq A_{i+1}, \quad Q_i \subseteq Q_{i+1}, \quad K_i \subseteq K_{i+1}, \quad \omega_{i+1} \mid_{Q_i} = \omega_i, \quad \partial A_{i+1} \mid_{A_i} = \partial A_i. \quad (6)$$

A filtered Morse complex consequently forms a standard filtration (Definition 1), with successive inclusions of complexes. It induces naturally a persistence module

$$H(A_1, F) \longrightarrow H(A_2, F) \longrightarrow \cdots \longrightarrow H(A_{n-1}, F) \longrightarrow H(A_n, F)$$

Forman’s isomorphism between homology groups of complexes and Morse complexes extends to persistent homology groups within this framework. Specifically,

**Theorem 3** (Forman [25], Mishaikow and Nanda [34]). Let $(A_i, Q_i, K_i, \omega_i)_{i=1,\ldots,n}$ be a standard Morse filtration for a filtration $X_1 \subseteq \ldots \subseteq X_n$. There exist collections of chain maps $(\psi_i : C(X_i) \rightarrow C(A_i))_{i=1,\ldots,n}$ and $(\varphi_i : C(A_i) \rightarrow C(X_i))_{i=1,\ldots,n}$ for which the following diagrams commute for every $i$

$$
\begin{array}{ccc}
C(X_i) & \subseteq & C(X_{i+1}) \\
\psi_i \downarrow & & \psi_{i+1} \downarrow \\
C(A_i) & \subseteq & C(A_{i+1})
\end{array}
\quad
\begin{array}{ccc}
C(X_i) & \subseteq & C(X_{i+1}) \\
\varphi_i \downarrow & & \varphi_{i+1} \downarrow \\
C(A_i) & \subseteq & C(A_{i+1})
\end{array}
$$

and $\varphi_i$ and $\psi_i$ induce isomorphisms at the homology level, that are inverses of each other. Consequently, these maps induce isomorphisms between the persistent modules of the filtration and the Morse filtration.

Without expressing them explicitly, we use the following properties of the map $\psi$ (see [34] for explicit formulations). First,

**Properties 1.** Let $X$ be a complex with a Morse matching $(A, Q, K, \omega)$. The chain map $\psi : C(X) \rightarrow C(A)$ can be expressed as the composition of elementary chain maps over all Morse pairs $(\tau, \sigma)$, taken in an arbitrary order,

$$\psi = \prod_{(\tau, \sigma), \text{ s.t. } \omega = \omega(\tau)} \psi_{\tau, \sigma}$$

where $\psi_{\tau, \sigma} : C(X') \rightarrow C(X' \setminus \{\tau, \sigma\})$ is defined on a “partially reduced” complex $X'$ to $X' \setminus \{\tau, \sigma\}$, with incidence functions induced by the partial matching. More specifically, $X'$ is a Morse complex of $X$ for a matching $(A', Q', K', \omega')$, such that $Q' \subseteq Q$, $K' \subseteq K$, and the restriction of $\omega$ to $Q'$ is equal to $\omega'$. The complex $X' \setminus \{\tau, \sigma\}$ is the Morse complex of $X$ with one more Morse pair $(\tau, \sigma)$. The set of Morse pairs already considered in $Q' \times K'$ is dependent of the order in which the maps are composed.

The map $\psi_{\tau, \sigma}$ satisfies:

1. $\psi_{\tau, \sigma}(\sigma) = 0$,

2. $\psi_{\tau, \sigma}(\tau)$ is a linear combination of facets of $\sigma$ in $X'$, and
(3) \( \psi_{\tau,\sigma}(\mu) = \mu \) for all \( \mu \neq \sigma, \tau \).

Similarly, the map \( \varphi: C(A) \rightarrow C(X) \) can be decomposed into

\[
\varphi = \prod_{(\tau, \sigma), \text{s.t. } \sigma = \omega(\tau)} \varphi_{\tau, \sigma}
\]

such that \( \varphi_{\tau, \sigma}: C(X' \setminus \{\tau, \sigma\}) \rightarrow C(X') \) and \( \psi_{\tau, \sigma}: C(X') \rightarrow C(X' \setminus \{\tau, \sigma\}) \) induce isomorphisms at the homology level, that are inverse of each other (defined on the appropriate domain and codomain).

**Zigzag persistence algorithms.** There are currently two practical\(^2\) approaches to compute zigzag persistent homology \([9, 10, 32]\). They both can be formulated in a unified framework \([31]\).

Given an input zigzag filtration:

\[
X_1 \xleftarrow{\subseteq} X_2 \xrightleftharpoons{\subseteq} \cdots \xleftarrow{\subseteq} X_{n-1} \xrightarrow{\subseteq} X_n ,
\]

both algorithms are iterative and maintain. At step \( i \) of the computation, they maintain a homology basis of \( H(X_i) \) that is compatible with the interval decomposition of the zigzag module associated to a zigzag filtration of the form

\[
X_1 \xleftarrow{\subseteq} X_2 \xrightleftharpoons{\subseteq} \cdots \xleftarrow{\subseteq} X_i \xrightarrow{\subseteq} \cdots \xrightarrow{\subseteq} X'_{i+m-1} \xrightarrow{\subseteq} X'_{i+m} ,
\]

The first \( i \) complexes and \( i-1 \) maps in (7) and (8) are identical, and the remaining complexes and maps of (8) are algorithm dependent. Both algorithms consists of updating the homology basis in order to maintain its compatibility when operating the following local transformations of the zigzag filtration/module in sequence

\[
\leftrightarrow X \xleftarrow{\sigma} X \cup \{\sigma\} \xrightarrow{\sigma} X \leftrightarrow \leftrightarrow X \xleftarrow{\sigma} X \cup \{\sigma\} \xrightarrow{\sigma} X \leftrightarrow \leftrightarrow X \cup \{\tau, \sigma\} \xleftarrow{\tau} X \cup \{\tau\} \xrightarrow{\tau} X \leftrightarrow (9) \quad (10) \quad (11)
\]

where each arrow represents the insertion of a cell. These transformations are called reflection diamonds for (9) and (10), and transposition diamond for (11), and their effect on the interval decomposition of the zigzag module have been characterized for general zigzag filtrations of complexes in \([31, 32]\). We give details on algorithm \([32]\), that we use later in Section 5 in Appendix A.

**3 Zigzag Morse filtration and persistent homology equivalence**

For a zigzag filtration of complexes \( F \), we define a canonical zigzag filtration \( M \) of Morse complexes admitting the same persistent homology.

### 3.1 Zigzag Morse filtration

Without loss of generality, consider the zigzag filtration

\[
\mathcal{F} := (\emptyset =) \ X_1 \xrightarrow{\Sigma_1} X_2 \xrightarrow{\Sigma_2} \cdots \xrightarrow{\Sigma_{2k-1}} X_{2k-1} \xrightarrow{\Sigma_{2k}} X_{2k} (= \emptyset)
\]

where the \( X_i \) are complexes, \( X_1 = X_{2k} = \emptyset \), and the \( i^{th} \) arrow is an inclusion, either forward (\( i \) odd) or backward (\( i \) even), where complexes \( X_i \) and \( X_{i+1} \) differ by a set of cells \( \Sigma_i \) (possibly empty). We decompose \( F \) further into atomic operations.

---

\(^2\) Putting aside \([33]\), which is essentially of theoretical nature.
Atomic operations. For each forward arrow $\bullet_i \rightarrow \bullet_{i+1}$, $i$ odd, let $(A_i, Q_i, K_i, \omega_i)$ be a Morse matching of the set of cells $\Sigma_i$.

Because Morse matchings are acyclic, there exists a total ordering of the cells of $\Sigma_i$, compatible with the face partial ordering of $\Sigma_i$, such that paired cells in $(A_i, Q_i, K_i, \omega_i)$ are consecutive with regard to that order. We can consequently decompose a forward inclusion $X_i \subseteq X_{i+1}$ into a sequence of inclusions of a single critical cell $\sigma \in A_i$, and of inclusions of a single Morse pair of cells $(\tau, \sigma) \in Q_i \times K_i$, as induced by the Morse matching $(A_i, Q_i, K_i, \omega_i)$.

For every backward arrow $\bullet_i \leftarrow \bullet_{i+1}$, $i$ even, the Morse matchings $(A_j, Q_j, K_j, \omega_j)$, for smaller odd indices $j < i$, induce a Morse matching on the cells of $X_i$. By restriction, they consequently induce a valid Morse matching on all cells of $\Sigma_i$, except on those cells $\sigma \in \Sigma_i$ that form a Morse pair $(\tau, \sigma)$, with $\tau \notin \Sigma_i$. We decompose backward arrows into a sequence of removals of a single critical cell, of removals of a single pair of matched cells, and of removals of a non-critical cell $\sigma$, without its paired cell $\tau \notin \Sigma_i$.

In summary, given an input filtration $\mathcal{F}$ as above, and the Morse matchings $(A_i, Q_i, K_i, \omega_i)$, we defined an atomic zigzag filtration

$$\mathcal{F} := (\emptyset =) X_1 \leftarrow \ldots \leftarrow X_{n-1} \leftarrow X_n (= \emptyset)$$

where all arrows are of the following types:

$$X \xleftarrow{\sigma} X' \quad (13) \quad X \xleftarrow{(\tau, \sigma)} X' \quad (14) \quad X \xrightarrow{\tau} X \setminus \{\sigma\} \quad (15)$$

where Diagrams (13) and (14) are forward or backward insertions of a critical cell $\sigma$ or a Morse pair $(\tau, \sigma)$ of cells, respectively, and Diagram (15) is the removal of a cell $\sigma$ from a Morse pair $(\tau, \sigma)$, where the cell $\tau$ is not removed. The identity arrow in this last diagram is a technicality that is clarified later. Naturally, one can recover the persistent homology of the zigzag filtration $\mathcal{F}$ from the one of $\mathcal{F}$, and we work with $\mathcal{F}$ for the rest of the article.

Morse filtration. Given a zigzag filtration $\mathcal{F}$, Morse matchings $(A_i, Q_i, K_i, \omega_i)$, and an associated atomic filtration $\mathcal{F}$ as above, we define a zigzag filtration

$$\mathcal{M} := (\emptyset =) A_1 \leftarrow \ldots \leftarrow A_{n-1} \leftarrow A_n (= \emptyset)$$

of Morse complexes $(A_i, \partial^{A_i})$ of the complexes $(X_i, \partial^{X_i})$ of $\mathcal{F}$ inductively. Note that, in the following, the maps of the zigzag Morse filtration are not all inclusions; in particular, the boundary map $\partial^{A_i}$ of the Morse complex may evolve in a non trivial fashion, i.e., for a critical cell $\sigma$ in both $X_i$ and $X_{i+1}$, in general $\partial^{A_i} \sigma \neq \partial^{A_{i+1}} \sigma$.

All $X_1, X_n, A_1$ and $A_n$ are empty complexes. At the level of chain complexes, the Morse filtration is constructed inductively for the insertion of a critical cell (Diagram (13) and the insertion of a Morse pair (Diagram (14))) as follows

$$C(X) \xleftarrow{\sigma'} C(X \cup \{\sigma'\}) \quad C(X) \xleftarrow{(\tau, \sigma)} C(X \cup \{\tau, \sigma\}) \quad \psi \quad \psi \quad \psi$$

$$C(A) \xleftarrow{\sigma'} C(A \cup \{\sigma'\}) \quad C(A) \xleftarrow{(\tau, \sigma)} C(A \cup \{\tau, \sigma\})$$

where all horizontal arrows are inclusions of complexes, and in particular the boundary maps of $A$ and $A \cup \{\sigma'\}$ are equal when restricted to the cells of $A$. The removal of critical cells and Morse pairs is symmetrical. The chain maps $\psi$ and $\psi_{\tau, \sigma}$ are the ones of Theorem 3 and Properties 4 and are used later.

For the removal of a non-critical cell $\sigma$ without its paired cell $\tau$ (Diagram (15)), the Morse filtration is constructed as follows

$$C(X) \xrightarrow{1} C(X) \xrightarrow{\sigma} C(X \setminus \{\sigma\}) \quad \psi \quad \psi$$

$$C(A, \partial) \xrightarrow{\varphi_{\tau, \sigma}} C(A \cup \{\tau, \sigma\}, \partial') \xrightarrow{\sigma} C(A \cup \{\tau\}, \partial'')$$
where the boundary maps $\partial$ and $\partial'$ differ in a non trivial way, studied in Section 3.2 and $\partial''$ is equal to the restriction of $\partial'$ to the critical cells $A \cup \{\tau\}$ (the right arrow is a backward inclusion of complexes). The chain maps $\psi_{\tau,\sigma}$ and $\varphi_{\tau,\sigma}$ are the ones from Theorem 3 and $\psi$ is the compositions of all maps $\psi_{\mu,\omega(\mu)}$ over the Morse pairs $(\mu, \omega(\mu))$ of the Morse matching of $X$, except the pair $(\tau, \sigma)$.

**Remark 1.** The zigzag Morse filtration defined above is identical to the filtered Morse complex of $[34]$ in the case of standard persistence, and, in that sense, the former is a generalization of the latter. The main novelty compare to the work of $[34]$ is the operation pictured in Diagram (17), which induces non trivial transformations in the Morse complex and the homology matrix, and which we study in details in the following sections.

Note that a key point for the proofs of theorems in $[34]$ is that filtered Morse complexes in standard persistence satisfy $(A_i, \partial) \subset (A_{i+1}, \partial)$. This fact also allows the standard persistent homology algorithm $[24, 38]$ to work directly for filtered Morse complexes. This property is not satisfied by zigzag Morse filtrations, which explains why our approach is more atomic than the one of $[34]$ (see Section 3.2), and that we have to design a new homology matrix algorithm to implement operation $[17]$ (see Sections 3 and 5).

### 3.2 Isomorphism of zigzag modules

The following lemma is proved in $[34]$ for standard persistent homology, and is a direct corollary of Theorem 3.

**Lemma 4.** Let $X$ be a complex and $(A, Q, K, \omega)$ a Morse complex obtained from $X$. Let $\sigma'$ be a cell, and $(\tau, \sigma)$ a Morse pair, such that $(A \cup \{\sigma'\}, Q, K)$ and $(A, Q \cup \{\tau\}, K \cup \{\sigma\})$ are valid Morse complexes. Then there exist isomorphisms $\psi_*$ and $(\psi_{\tau,\sigma})_*$ such that the following diagrams commute:

\[
\begin{array}{ccc}
H(X) & \xrightarrow{\sigma'\circ \psi} & H(X \cup \{\sigma'\}) \\
\psi_* & \downarrow & \psi_* \\
H(A) & \xrightarrow{\sigma_*} & H(A \cup \{\sigma'\})
\end{array}
\quad \quad \quad
\begin{array}{ccc}
H(X) & \xrightarrow{\sigma_* \circ \tau_*} & H(X \cup \{\tau, \sigma\}) \\
\psi_* & \downarrow & \psi_* \\
H(A) & \xrightarrow{1} & H(A)
\end{array}
\]

where $\sigma'_*$ and $\sigma_* \circ \tau_*$ are the maps induced at homology level by the insertion of $\sigma'$ and $\{\tau, \sigma\}$ respectively. The maps $\psi_*$ and $(\psi_{\tau,\sigma})_*$ are the isomorphisms induced by chain maps $\psi$ and $\psi_{\tau,\sigma}$ of Morse theory (see Theorem 3).

We prove the following lemma, that is specific to the zigzag persistence case.

**Lemma 5.** Let $X$ be a complex and $(A, Q, K, \omega)$ a Morse complex obtained from $X$. Let $\sigma$ be a maximal cell of $X$ not in $A$, which therefore forms a Morse pair with a cell $\tau$, $[\sigma : \tau]^X \neq 0$. There exist isomorphisms $\psi_*$, $(\psi_{\tau,\sigma})_*$, and $(\varphi_{\tau,\sigma})_*$, such that the following diagram commutes:

\[
\begin{array}{ccc}
H(X) & \xrightarrow{1} & H(X) \\
(\psi_{\tau,\sigma})_* \circ \psi_* & \downarrow & (\psi_{\tau,\sigma})_* \circ \psi_* \\
H(A) & \xrightarrow{\sigma_*} & H(A \cup \{\tau, \sigma\})
\end{array}
\]

where $\sigma_*$ is the map induced at homology level by the removal of $\sigma$. The maps $\psi_*$, $(\psi_{\tau,\sigma})_*$, and $(\varphi_{\tau,\sigma})_*$, are the isomorphisms induced at homology level by, respectively, the chain maps $\psi$, $\psi_{\tau,\sigma}$, and $\varphi_{\tau,\sigma}$ of Morse theory (see Theorem 3).

**Proof.** Consider Diagram (17). By virtue of Lemma 4 the right square commutes. Because the maps induced at homology level by $\psi_{\tau,\sigma}$ and $\varphi_{\tau,\sigma}$ are isomorphisms, inverse of each other (see Theorem 3 and Properties 4), we get

\[(\varphi_{\tau,\sigma})_* \circ (\psi_{\tau,\sigma})_* \circ \psi_* = \psi_*\]

and the left square commutes. By Theorem 3 the maps $\psi$, $\psi_{\tau,\sigma}$, and $\varphi_{\tau,\sigma}$ are isomorphisms. □

We conclude,
Theorem 6. The zigzag filtrations $\mathcal{F}$ and $\mathcal{M}$ have same persistent homology.

Proof. Applying the homology functor to $\mathcal{F}$ and $\mathcal{M}$, we get the zigzag modules

$$
\begin{align*}
H(\mathcal{F}) & : H(X_0) \xrightarrow{\psi_0^2} H(X_1) \xrightarrow{\psi_1^2} \cdots \xrightarrow{\psi_m^2} H(X_m) \\
H(\mathcal{M}) & : H(A_0) \xrightarrow{\psi_0^\tau} H(A_1) \xrightarrow{\psi_1^\tau} \cdots \xrightarrow{\psi_m^\tau} H(A_m)
\end{align*}
$$

where, by construction, every $A_i$ is a Morse complex of $X_i$, and the $\psi_i^\tau$ are the isomorphism induced by the chain map $\psi_i : C(X_i) \to C(A_i)$, connecting a complex and its Morse reduction (Theorem 5).

By Lemmas 4 and 5 all squares commute and are compatible with each other, and the $\{\psi_i^\tau\}$ define an isomorphism of zigzag modules.

4 Boundary of the filtered Morse complex

Referring to Diagram (17), let $X$ be a complex with incidence function $\cdot : \cdot \to X$, together with a Morse matching $(\mathcal{A}, Q, K, \omega)$, giving and oriented Hasse diagram $\mathcal{H}$ for that matching, and a Morse complex $(\mathcal{A}, \partial)$.

In this section, we study in details the evolution of the boundary operators in Morse complexes under the evaluation of the map $\varphi_{\tau, \sigma} : (\mathcal{A}, \partial) \to (A \cup \{\tau, \sigma\}, \partial')$ from Diagram (17). Both complexes are Morse complexes of the same $X$, whose matchings differ by exactly one pair $(\tau, \sigma)$, i.e., the Morse partition of complex $A \cup \{\sigma, \tau\}$ is $(A \cup \{\tau, \sigma\}) \cup (Q \setminus \{\tau\}) \cup (K \setminus \{\sigma\})$. We denote this last complex by $(\mathcal{A}', \partial')$, with incidence function $\cdot : \cdot \to A'$ in the following.

We prove the following property of the boundary operator $\partial'$ of $\mathcal{A}'$, where $\sigma$ is maximal in $X$ (as in Diagram (17)), and consequently maximal in $A \cup \{\tau, \sigma\}$.

Lemma 7. Let $\nu$ be a cell of the complex $(\mathcal{A}, \partial)$. Then, in the complex $(\mathcal{A}', \partial')$,

$$
\partial'(\nu) = \partial(\nu) + \left([\sigma : \tau]^X\right)^{-1} [\nu : \tau]^A \cdot \partial \sigma \tag{18}
$$

Proof. Let $\mathcal{H}$ and $\mathcal{H}'$ be, respectively, the Hasse diagram of $X$ induced by the Morse matching of $\mathcal{A}$ and of $\mathcal{A}'$. Because the matchings differ by a single Morse pair $(\tau, \sigma)$, $\mathcal{H}$ and $\mathcal{H}'$ only differ by the orientation of the edge $\tau \leftrightarrow \sigma$.

For a critical cell $\nu \in \mathcal{A}$, we have

$$
\partial \nu = \sum_{\nu \in \mathcal{A}} m(\gamma) \cdot \mu = \sum_{\nu \in \mathcal{A}} m(\gamma) \cdot \mu + \sum_{\nu \in \mathcal{A}} m(\gamma) \cdot \mu = \sum_{\nu \in \mathcal{A}} m(\gamma) \cdot \mu + \partial' \nu
$$

where $\Gamma_{\tau \to \sigma}(\nu, \mu)$ are the gradient paths from $\nu$ to $\mu$ in $\mathcal{H}$ containing the upward arrow $\tau \to \sigma$, and $\Gamma_{\tau \to \sigma}(\nu, \mu)$ are the ones not containing it. Assume $\tau$ is of dimension $d$, and $\sigma$ of dimension $d + 1$.

Because $\sigma$ is critical in $\mathcal{A}'$, it has no ingoing arrow from cells of dimension $d$ in $\mathcal{H}'$. Consequently, $\Gamma_{\tau \to \sigma}(\nu, \mu)$ contains exactly all gradient paths from $\nu$ to $\mu$ in $\mathcal{H}'$, where $\mu \neq \tau$. Hence, the sum over $\Gamma_{\tau \to \sigma}(\nu, \mu)$, for $\mu \in \mathcal{A}$, gives $\partial' \nu - [\nu : \tau]^A \cdot \tau$. Note that $\sigma$ cannot appear in $\partial' \nu$ because $\sigma$ is maximal by hypothesis.

Now, studying the left term $(\star)$, and splitting gradient paths passing through edge $(\tau, \sigma)$, then factorizing, we get

$$(\star) = \sum_{\nu \in \mathcal{A}, \gamma_1 \in \Gamma(\nu, \tau), \gamma_2 \in \Gamma(\nu, \mu)} m(\gamma_1) \cdot \left(-[\sigma : \tau]^X\right)^{-1} m(\gamma_2) \cdot \mu = -\left([\sigma : \tau]^X\right)^{-1} \sum_{\nu \in \mathcal{A}, \gamma_1 \in \Gamma(\nu, \tau)} m(\gamma_2) \cdot \mu \cdot \sum_{\nu \in \mathcal{A}, \gamma_1 \in \Gamma(\nu, \tau)} m(\gamma_1)
$$

The sum $(\star_1)$ over $\Gamma(\nu, \tau)$ is independent of $\mu$, and equal to $[\nu : \tau]^A$ by definition.
Because $\tau$ is critical in $\mathcal{A}'$, it has no outgoing arrow towards cells of dimension $d+1$ in $\mathcal{H}'$. Consequently, $\Gamma(\sigma, \mu)$ contains exactly all gradient paths from $\sigma$ to $\mu$ in $\mathcal{H}'$, where $\mu \neq \tau$. Hence, the sum $(\ast_2)$ over $\Gamma(\sigma, \mu)$ gives $\partial'\sigma - |\sigma : \tau|$$^X_\tau$.

Finally, putting terms together,

$$\partial\nu = \left(\partial'\nu - [\nu : \tau]^{\mathcal{A}'}_{\mathcal{A}'}\right) - \left[\nu : \tau\right]^{\mathcal{A}'}_{\mathcal{A}'}\left(\partial'\sigma - |\sigma : \tau|$$^X_\tau\right) = \partial'\nu - \left[\nu : \tau\right]^{\mathcal{A}'}_{\mathcal{A}'}\partial'\sigma$$

\[\square\]

5 Zigzag persistence algorithm for zigzag Morse complexes

In this section, we describe an algorithm to compute the persistent homology of a zigzag Morse filtration as defined in Section 3. For the sake of concision, and for its favorable practical performance (see Section 6), we choose to work with the algorithm for zigzag persistence described in [32]; our approach could be adapted for implementing algorithm [9, 10].

Using notations from Section 3, let $\mathcal{F}$ be a general zigzag filtration

$$\mathcal{F} := (\emptyset =) X_1 \to X_2 \to \cdots \to X_j$$

together with Morse matchings ($\mathcal{A}_i, \mathcal{Q}_i, \mathcal{K}_i, \omega_i$) on the set of cells $\Sigma_i$ of every forward inclusion $X_i \to X_{i+1}, i$ odd.

Let $\mathcal{F}$ be the associated atomic zigzag filtration of complexes where all maps are forward or backward inclusions of a single cell: $\mathcal{F} : X_1 \to X_2 \to \cdots \to X_n$.

Algorithm [32] maintains, at step $j$ of the computation, a homology matrix $H(X_j)$ at the complex $X_j$, that is compatible (defined later) with the following filtration $\mathcal{F}_j$,

$$\mathcal{F}_j : X_1 \to X_2 \to \cdots \to X_j \xrightarrow{\sigma_1} X_{j+1} \xrightarrow{\sigma_2} \cdots \xrightarrow{\sigma_{m-1}} X_{j+m-1} \xrightarrow{\sigma_m} X_{j+m} = \emptyset$$

(19)

The first $j$ complexes, and maps between them, are identical in $\mathcal{F}$ and $\mathcal{F}_j$, and the last $m$ maps of $\mathcal{F}_j$ are backward inclusions of a single cell, i.e., $X_j$ contains $m$ cells. At step $j$, algorithm [32] proceeds by applying reflection diamonds (9) at index $j$, and transposition diamonds (11) at indices $j+r, r > 0$, which allows one to handle insertions and removal of a cell. We refer the reader to Appendix A for details on the implementation of algorithm [32].

For zigzag Morse filtrations, existing zigzag persistence algorithms [9, 10, 32] can consequently handle inclusions and removals of critical cells that, as pictured in Diagram (16), are standard forward and backward inclusions of general complexes. In the following, we focus on the new update (17), that introduces the chain map $\varphi_{r, \tau}$ that is not an inclusion.

Zigzag Morse filtration for computation. For indices $1 \leq p \leq q \leq n$, denote by $\mathcal{F}[p; q]$ the restriction of the filtration $\mathcal{F}$ to spaces of indices $i \in [p; q]$, and maps between them.

At step $j$ of the algorithm, we maintain a zigzag Morse filtration $\mathcal{M}_j$ for the filtration $\mathcal{F}_j$. At space $X_j$, the filtration satisfies:

Properties 2 (Zigzag Morse filtration $\mathcal{M}_j$).

(1) the filtration $\mathcal{M}_j[1; j]$ is a general zigzag Morse filtration (defined in Section 3.1) for $\mathcal{F}[1; j]$ and its Morse matchings $\{(\mathcal{A}_i, \mathcal{Q}_i, \mathcal{K}_i, \omega_i)\}_{i=1\ldots j}$,

(2) the filtration $\mathcal{M}_j[j; j+m]$ is a standard Morse filtration (defined in [32] and Equation (6)) for the standard filtration $\mathcal{F}_j[j; j+m]$.

Before exhibiting the filtrations, we prove the following simple property of the zigzag persistence algorithm,
Lemma 8. Let \( \tau, \sigma \) be cells of \( X_j \), such that maps \( X_p \rightarrow \tau \rightarrow X_{p+1} \) and \( X_q \rightarrow \sigma \rightarrow X_{q+1} \) in \( \mathcal{F} \) have the largest indices \( 1 \leq p, q < j \) for which a forward inclusion of \( \tau \) and \( \sigma \), respectively, happens in \( \mathcal{F}[1;j] \).

Let indices \( 1 \leq r, s \leq m \) be such that \( X'_{j+r-1} \leftarrow \tau \rightarrow X'_{j+r} \) and \( X'_{j+s-1} \leftarrow \sigma \rightarrow X'_{j+s} \) are the backward inclusions of \( \tau \) and \( \sigma \) in the part \( \mathcal{F}_j[j;j+m] \) of the filtration \( \mathcal{F}_j \). Then,

\[
p < q \quad \text{iff} \quad s < r
\]

In other words, if \( \tau \) is inserted before \( \sigma \), it is removed after \( \sigma \).

**Proof.** The only “new” arrows in the diagram are brought by the reflection diamonds \( \Psi \) applied at index \( j \) of the algorithm, on \( \mathcal{F}_j \), which induces the desired symmetry in forward and backward arrows for the insertion of a given cell. We refer to [22] for details on the algorithm. \( \square \)

Now, consider the following diagram, where \(( \tau, \sigma ) \) are cells of \( X_j \) which are paired in the Morse matching of \( X_j \) induced by the Morse matchings \( \{ (A_i, Q_i, K_i, \omega_i) \}_{i=1...j} \) of the filtration,

\[
\begin{align*}
\mathcal{F}_j : & \quad \leftarrow \cdots \leftarrow X_j \quad \leftarrow X_{j+1} \quad \leftarrow X'_{j+r} \quad \leftarrow X_{j+r+1} \quad \leftarrow \cdots \leftarrow X_{j+r-2} \leftarrow \cdots \\
\mathcal{A}_j : & \quad \leftarrow \cdots \leftarrow A_j \quad \leftarrow A'_{j+r} \quad \leftarrow A_{j+r+1} \quad \leftarrow \cdots \leftarrow A_{j+r-2} \leftarrow \cdots \\
\mathcal{M}_j : & \quad \leftarrow \cdots \leftarrow A_j \quad \leftarrow \sigma, \tau \leftarrow A'_{j+r+1} \leftarrow \cdots \leftarrow A_{j+r-2} \leftarrow \cdots
\end{align*}
\]

where arrows without label are simple inclusions of complexes. Simplifying notations, we denote by \( X \) the complex \( X'_{j+r-1} \), by \( A \) the complex \( A'_{j+r-1} \), and union of a complex and some cells by \( X, \sigma, \tau \), instead of \( X \cup \{ \sigma, \tau \} \). We use this diagram until the end of the section, and define its various components progressively.

Lemma 6 ensures that \( \tau \) and \( \sigma \), that are consecutively inserted (Morse pair, Diagram (13)), are consecutively removed in \( \mathcal{F}_j[j;j+m] \), as pictured above. The filtration \( \mathcal{F}_j \) appears on top, where two arrows (curved horizontal) are further decomposed for convenience.

By induction, let \( \mathcal{M}_j \) be the zigzag Morse filtration maintained by the algorithm at step \( j \), and satisfying Properties (2). Performing reflection diamonds \( \Psi \) at index \( j \), and transposition diamonds \( 1 \) at indices \( j+r \), \( r > 0 \), maintains the Properties (2) Consequentially, at the level of the zigzag Morse filtration, the zigzag algorithm [22] can implement insertions and deletions of critical cells (Diagrams (16)) with no further modification, while maintaining a Morse filtration \( \mathcal{M}_j \Rightarrow \mathcal{M}_{j+1} \) satisfying the algorithmic invariant Properties (2).

The only obstruction to using the zigzag persistence algorithm in the operation introduced in Diagram (14). Consequently, consider the next operation in \( \mathcal{F} \) to be the removal \( X_j \leftarrow \tau \rightarrow X_{j+1} \) of a non-critical cell \( \sigma \), paired with a cell \( \tau \) in the Morse matching of \( X_j \), such that \( \tau \) is not removed.

The cell \( \sigma \) cannot be “directly removed” as it does not appear in \( \mathcal{M}_j[j;j+m] \). We focus the rest of this section to the definition and study of the zigzag Morse filtration \( \overline{\mathcal{M}}_j \) of Diagram (20).

Let \( \overline{\mathcal{M}}_j \) be as above, where the map \( \varphi_{\tau, \sigma} \) is the map defined in Diagram (14), and the chain maps \( \psi \) between \( \mathcal{F}_j \) and \( \overline{\mathcal{M}}_j \) are the ones of Diagrams (16) and (17). By Lemmas 3 and 5, these maps induce an isomorphism of zigzag modules \( H(\mathcal{F}_j) \rightarrow H(\overline{\mathcal{M}}_j) \), and the filtrations have same persistent homology. Additionally, \( \overline{\mathcal{M}}_j \) is a zigzag Morse filtration, and a standard Morse filtration from space \( A_j, \sigma, \tau \) on to the right, i.e., it satisfies Properties (2). Finally, \( \sigma \) is critical in \( A_j, \sigma, \tau \), and can be removed with the zigzag persistence algorithm to obtain \( \mathcal{M}_{j+1} \).

**Compatible homology matrix.** We design an algorithm to turn a homology matrix at \( A_j \), compatible with \( \mathcal{M}_j \), into a homology matrix at \( A_j, \sigma, \tau \), compatible with \( \overline{\mathcal{M}}_j \).

Consider an arbitrary zigzag filtration of complexes as in Diagram (19), where arrows on the left of \( X_j \) are arbitrary chain maps, and arrows on the right of \( X_j \) are backward inclusions of single cells \( \sigma_r \), and \( X_{j+m} = \emptyset \), i.e., \( X_j \) contains \( m \) cells.

\[11\]
Lemma 9. The collection of facets of only differ by the orientation of arrow $\sigma$ that critical cell $\tau$.

Proof. We prove that $\mathcal{B}$ is a homology matrix at $X_j$ if

1. for all $0 \leq r < m$, the space generated by $\langle c_r, \ldots, c_{m-1} \rangle$ is equal to $C(X_{j+r})$, and $C(X_j)$ if $r = 0$,

and there exists a partition $\{0, \ldots, m-1\} = F \sqcup G \sqcup H$, and a bijective pairing $G \leftrightarrow H$, satisfying:

2. for all indices $f \in F$, $\partial^X c_f = 0$,

3. for all indices $g \leftrightarrow h$ of $G \times H$, $\partial^X c_h = c_g$.

This data encodes the persistent homology of the (standard) filtration $F_j$ at $F$. In particular, the homology groups of $X_j$ are equal to $\langle [c_f] : f \in F \rangle$. It is convenient to see this data as a matrix $M_B$ with cycle $c_i$ as $i$th column, expressed in the basis $\{\sigma_i\}_{i=1 \ldots m}$ for rows. In this case, condition (1) of the definition is equivalent to the matrix being upper triangular, with no zero entry in the diagonal.

Additionally,

Definition 3. Denote by $\oplus_i [b_i; d_i]$ the interval decomposition of $H(F_j)$. A homology matrix $B = \{c_0, \ldots, c_{m-1}\}$ at $X_j$ is compatible with the filtration $F_j$ if there exists a zigzag module isomorphism $\Phi: H(F) \to \oplus_i [b_i; d_i]$ such that $\Phi_j: H(X_j) \to \oplus_i [b_i; d_i]$ sends $\{[c_f] : f \in F\}$ to the canonical basis of $F \times \cdots \times F$.

Algorithm maintains at step $j$ a homology basis at $X_j$ compatible with $F_j$. We now define, from a homology matrix $B$ at $A_j$, compatible with $M_j$, a homology matrix $B$ at $A_j, \sigma, \tau$, compatible with $M_j$.

Going back to Diagram (24), denote the complexes, and their boundary maps, connected by map $\phi_{\tau, \sigma}$ in $M_j$ by $(A_j, \partial)$ and $(A_j', \partial')$, with $A_j' := A_j, \sigma, \tau$. Let $B = \{c_0, \ldots, c_{m-1}\}$ be a homology matrix at $A_j$ compatible with $M_j$. Define the chains $B := \{c'_0, \ldots, c'_{m-1}, c_\sigma, c_\tau\}$ of $A_j, \sigma, \tau$, such that

1. for all indices $i \in F \sqcup H$, define $c'_i := c_i - (\sigma : \tau)^X \sum_{\nu \in \ell} [\nu : \tau]^A \cdot \sigma$.

2. define $c_\tau := \partial' \sigma$, and $c_\sigma := \sigma$, and put the index of $c_\tau$ in $G$, the index of $c_\sigma$ in $H$, and pair them together,

3. the pairing $G \leftrightarrow H$ inherited from $B$ remains unchanged, as well as the set of indices $F$.

We prove,

Lemma 9. The collection $B$ is a homology matrix at $A_j, \sigma, \tau$ in Diagram (24).

Proof. We prove that $B$ satisfies the three conditions of Definition 2 for the filtration $M_j \cup [j; j+m]$ of Diagram (24).

(1). Consider the matrix $M_B$, where columns $c_\tau, c_\sigma$ (respectively rows $\tau, \sigma$) are inserted between indices $j+r-1$ and $j+r$, as in Diagram (24). We prove that this matrix is upper triangular.

Case $c_\tau, c_\sigma$. The lowest non-zero entry of column $c_\sigma$ is in row $\tau$. We prove that the lowest non-zero entry of column $c_\tau$ is in row $\tau$, i.e., reading the filtration $M_j \cup [j; j+m]$ of the Morse complex $A_j, \sigma, \tau$ (Diagram (24)) from right to left, $\tau$ is the last inserted cell $\mu$ such that $(\partial' \sigma, \mu) = 0$.

Let $H$ be the oriented Hasse diagram of $X_j$ for the Morse matching where $(\tau, \sigma)$ forms a Morse pair (complex $A_j$), and $H'$ for the matching where $\tau$ and $\sigma$ are critical (complex $A_j, \sigma, \tau$); they only differ by the orientation of arrow $\sigma \leftrightarrow \tau$.

First, $(\partial' \sigma, \tau) = 0$ because there exists a unique gradient path from critical cell $\sigma$ to critical cell $\tau$ in $X_j$. The path $\gamma$ exists because $\tau$ is a facet of $\sigma$ in $X_j$. If there were another distinct gradient path from $\sigma$ to $\tau$ in $H'$, not containing the
edge $\sigma \to \tau$, this path would exist in $H$ and form a cycle with edge $\tau \to \sigma$ in $H$; a contradiction with the definition of Morse matchings.

Second, if $\mu \in A_j, \sigma, \tau$ is a critical cell such that $[\sigma : \mu]_{A_j, \sigma, \tau} \neq 0$, then $\mu$ is inserted before $\sigma$ in the filtration $F_j$ (read from right to left). Indeed, there exists a gradient path $\gamma = (\sigma, \mu_1, \omega(\mu_1), \ldots, \omega(\mu_{r-1}), \omega(\mu_r) = \mu)$ from $\sigma$ to $\mu$ in $H$. The cells $\omega(\mu_i)$ of a pair are inserted consecutively by construction, and, for all $i = 2 \ldots r$, $\mu_i$ is inserted before $\omega(\mu_{i-1})$ because it is a facet in $X_j$. By transitivity, $\mu$ is inserted before $\sigma$. In view of $M_j$ in Diagram (20), $\tau$ is the last inserted cell of the boundary of $\sigma$. The lowest non-zero entry of column $c_\tau = \partial'\sigma$ is consequently in row $\tau$.

**Case $c'$.** If $c' = c_i$, then if row $\nu_0$ contains the lowest non-zero entry of column $c_i$ in $M_{BG}$, then row $\nu_0$ also contains the lowest non-zero entry of column $c'_i$ in $M_{\pi}$.

By construction, all chains $c_i$ becoming $c'_i = c_i + \alpha \cdot \sigma$, $\alpha \neq 0$, contains cells $\nu$ such that $[\nu : \tau]_{A_j, \sigma, \tau} \neq 0$, i.e., cofacets of $\tau$ in $A_j, \sigma, \tau$. Reading $M_{\pi}[j; j + m]$ from right to left, these cells $\nu$ must consequently appear after $\tau$, and hence after $\sigma$, in the filtration, with a similar transitivity argument as above. Consequently, if row $\nu_0$ contains the lowest non-zero entry of column $c_i$ in $M_{BG}$, then row $\nu_0$ also contains the lowest non-zero entry of column $c'_i$ in $M_{\pi}$.

Consequently, $M_{BG}$ upper triangular implies $M_{\pi}$ is upper triangular.

(2). Let $c_i$ be a chain such that $i \in F \cup H$. By Lemma 7, it is a direct calculation from the definition of $c'_i$ that $\partial' c'_i = \partial c_i$. Consequently, Conditions (2) and (3) of Definition 2 are satisfied for those chains. The pairing $G \leftrightarrow H$ remains valid, because $\partial' c'_h = \partial c_h = c_g = c'_g$ for $g \leftrightarrow h$, $(g, h) \in G \times H$.

(3). By definition, $\partial' c_\sigma = c_\tau$, their indices are in $H \times G$ and paired together.

**Lemma 10.** The homology matrix $\mathbf{B}$ at $A_j, \sigma, \tau$ is compatible with $M_j$ in Diagram (20).

**Proof.** By hypothesis, $B = \{c_0, \ldots, c_{m-1}\}$ is a homology matrix at $A_j$, compatible with $M_j$; let $\Omega : H(M_j) \to \oplus_k [b_k; d_k]$ be a zigzag module isomorphism such that $\Omega_j$ sends $\{c_f\} : f \in F$ to the canonical basis of $\mathbb{F} \times \ldots \times \mathbb{F}$.

Note that, none of the $c'_i$ have an entry $\tau$, except for $c_\tau$ whose index is in $G$ by construction. Consequently, by Properties 4 the chain map $\psi_{\tau, \sigma} : C(A_j, \sigma, \tau) \to C(A_j)$ simply cancels the entry $\sigma$ in every $c'_f, f \in F$, and $\psi_{\tau, \sigma} c'_f = c_f$. Consequently, consider the chain maps between $M_j$ and $M_j$ in Diagram (20). Each square commutes by virtue of Theorem 5 (for inclusions) and Lemma 5 (for $\varphi_{\tau, \sigma}$), and they induce an isomorphism $\Phi_* : H(M) \to H(M)$ of zigzag modules. The isomorphism $\Omega \circ \Phi_* : H(M) = \oplus_k [b_k; d_k]$ sends $\{c_f\} : f \in F$ to the canonical basis of $\mathbb{F} \times \ldots \times \mathbb{F}$, and $\mathbf{B}$ is compatible with $M$.

In conclusion, for an input atomic zigzag operation $F$, with three atomic maps pictured in Diagrams (13), (14), and (15), the Morse algorithm for computing the zigzag persistence of $F$ is depicted in Algorithm 11 where zigzag persistence algorithm($M_{BG}, M_j, \sigma$) is the zigzag persistence algorithm of 32 to handle forward or backward insertions of a single cell in a homology matrix $M_{BG}$ at complex $A_j$, compatible with the filtration $M_j$ (see Diagram 20). Each iteration of the for loop turns a homology matrix $M_{BG}$ at complex $A_j$, compatible with the filtration $M_j$, into a homology matrix at complex $A_{j+1}$, compatible with the filtration $M_{j+1}$, where $M_{j+1}$ is a zigzag Morse filtration for $F_{j+1}$, and $A_j$ and $A_{j+1}$ are respectively Morse complexes for $X_j$ and $X_{j+1}$.

**Implementation and complexity.** We represent $\mathcal{B} = \{c_0, \ldots, c_{m-1}\}$ by an $(m \times m)$-sparse matrix data structure $M_{BG}$. Assume computing boundaries and coboundaries in a Morse complex is given by an oracle of complexity $C$. We implement the transformation $\mathcal{B} = \{c_0, \ldots, c_{m-1}\} \rightarrow \mathcal{B}' = \{c'_0, \ldots, c'_{m-1}, c_\sigma, c_\tau\}$ presented above by:

1. computing the boundary $\partial' \sigma$ of $\sigma$ in $A_j, \sigma, \tau$, and the coboundary $\{\nu : [\nu : \tau]_{A_j, \sigma, \tau} \neq 0\}$ of $\tau$, in $O(\mathcal{C})$ operations,

2. adding columns $c_\tau$ and $c_\sigma$ to the matrix, in the appropriate position as in Diagram (20), in $O(m)$ operations,
Algorithm 1: Zigzag persistence algorithm for Morse filtrations

**input:** atomic zigzag filtration
\[ F := (\emptyset =) X_1 \leftarrow X_2 \leftarrow \ldots \leftarrow X_{n-1} \leftarrow X_n (= \emptyset) \]

**output:** persistent homology of \( F \)

1. set \( M_B \leftarrow \emptyset \);
2. for \( j = 1 \ldots n - 1 \) do
   3. if \( X_j \leftarrow^\sigma X_{j+1}, \sigma \in X_j \) critical then
      4. use zigzag persistence algorithm \((M_B, M_j, \sigma)\) to add or remove \( \sigma \);
   5. end
   6. if \( X_j \leftarrow \{\tau, \sigma\} \to X_{j+1}, (\tau, \sigma) \) Morse pair then
      7. do nothing;
   8. end
   9. if \( X_j \leftarrow^\sigma X_{j+1}, \sigma \) paired with \( \tau, \tau \) not removed then
      10. set \( M_B \leftarrow \overline{M_B} \) as described above;
      11. use zigzag persistence algorithm \((M_B, \overline{M_j}, \sigma)\) to remove \( \sigma \);
   12. end
3. end

3. computing \( c'_i \) for all \( i \), in \( O(m^2) \). We can restrict the transformation to those \( c_i \) containing a cell of the coboundary of \( \tau \).

Consequently, we can perform the transformation above in \( O(m^2 + C) \) operations on a \((m \times m)\)-matrix. The zigzag persistence algorithm of [32] deals with forward and backward insertions of a single cell in \( O(m^2) \) operations.

In conclusion, let \( F = (X_i \leftarrow \Sigma_i \to X_{i+1})_{i=1 \ldots 2k} \) be a general zigzag filtration (Diagram 12), and let \( M \) be a zigzag Morse filtration as defined in Section 3 for a collection of Morse matchings \((A_i, Q_i, K_i, \omega_i)\) on \( \Sigma_i, i \) odd. Using the notations

- for all \( i, 1 \leq i \leq 2k - 1 \), denote by \( n_i \) the number of distinct critical cells between consecutive Morse complexes \( A_i \) and \( A_{i+1} \) in \( M \),
- denote by \( n \) the sum of the \( n_i \), \( 1 \leq i \leq 2k - 1 \),
- denote by \( |A_m| \) the maximal number of critical cells of a Morse complex in \( M \).

and for the original filtration,

- denote by \( N \) the total number of insertion and deletion of cells in \( F \),
- denote by \( |X_m| \) the maximal number of cell of a complex in \( F \).

We have,

**Theorem 11.** The persistent homology of \( F \) can be computed in
\[ O(n \cdot |A_m|^2 + nC) \]
operations, where \( C \) is the complexity of computing boundaries and coboundaries in the Morse complexes.

To compare with the usual complexity of (practical) zigzag persistence algorithms [9, 10, 32], which is \( O(N \cdot |X_m|^2) \).

Note that our algorithm requires the Morse matchings, implicitly encoded by the atomic filtration \( F \). Even though computing optimal Morse matchings is hard in general [27], fast heuristics exist in practice to compute Morse matchings with (usually) few critical cells (see for example [6]).
6 Experiments

In this section, we report on the performance of the zigzag persistence algorithm \cite{2} with and without Morse reduction.

The following tests are made on a 64-bit Linux (Ubuntu) HP machine with a 3.50 GHz Intel processor and 63 GB RAM. The programs are all implemented in C++ and compiled with optimization level -O2 and gcc-8. Memory peaks are obtained via the /usr/bin/time -f Linux command, and timings are measured via the C++ std::chrono::system_clock::now() method. Each measurement of time and memory is taken as the average over 10 independent runs.

All zigzag filtrations in our experiments are oscillating Rips zigzag filtrations \cite{37}, which are popular filtrations of simplicial complexes for homological inference on point clouds. The Rips radii depend on two multiplicative parameters $\eta \leq \rho$. Under the right sampling conditions, if $\rho$ is large enough, and $\eta$ substantially smaller than $\rho$, the reconstruction is provably correct \cite{37}. The results and the chosen parameters are in Table 1, and fit within the values defined by the theory of zigzag persistence inference.

We use both synthetic and real data. The point clouds KlBt5, Spi3, Sph3, and To3 are synthetic samples of respectively the 5-dimensional Klein bottle, a 3-dimensional spiral wrapped around a torus, the 3-dimensional sphere, and the 3-dimensional torus. The point cloud MoCh and By are 3-dimensional measured samples of surface models: the MotherChild model, and the Stanford bunny model from the Stanford Computer Graphics Laboratory.

| Experiment | $|E|$ | Number of inclusions | Number of removals | Max. size of complex | Time (s) | Mem. peak (kB) |
|------------|------|----------------------|--------------------|---------------------|----------|---------------|
| KlBt5      | 5    | 323 078              | 130 162            | 161 470             | 3188     | 33,5 + 3,7    | 44048  |
| Spi3       | 6    | 533 506              | 108 569            | 124 293             | 3222     | 59,9 + 5,2    | 37579  |
| MoCh       | 6    | 700 520              | 53 707             | 82 255              | 3940     | 54,9 + 5,2    | 43015  |
| Sph3       | 7    | 620 493              | 96 557             | 107 817             | 2890     | 18,5 + 5,0    | 38338  |
| To3        | 8    | 816 591              | 71 335             | 86 865              | 3243     | 353,0 + 7,1   | 50540  |
| By         | 8    | 1 002 367            | 19 728             | 39 498              | 3234     | 77,5 + 10,6   | 55759  |

Table 1: Experimental results. For each experiment, the maximal dimension is 10, $\eta = 4$ and the number of vertices is 500. $|E|$ is the number of edges in the original oscillating Rips zigzag filtrations, from which the filtration is computed. The timings are given in two parts: ‘cpx’ is the computational time for the complex operations (construction, boundary and coboundary operations) and ‘pers’ is the computation time of the actual zigzag persistence.

Analysis of the results. The results show a good improvement of the persistence computation time, from approximately 10 to 17 times faster. This is due to filtrations being from 19 to 333 times shorter than the original one (quantities $n$ vs $N$ in the complexity analysis) and smaller complexes, from 6 to 17 smaller with the Morse reduction (quantities $|A_m|$ and $|X_m|$ in the complexity
The Morse reduction also reduces the memory consumption from 7 to 18 times. This is due to the maintenance of a substantially smaller homology matrix during computation.

Note that we use a naive implementation of the Morse complex operations, which slows down computations on some data sets (like To3). We plan to use a more optimized implementation of Morse matchings for the final version of this article, in order to circumvent this issue.

A Zigzag persistence algorithm for complexes and inclusions

For completeness, we recall details of the algorithm for computing zigzag persistence introduced in [32], with the notations of Section 5.

Let \( F : X_1 \rightarrow X_2 \rightarrow \cdots \rightarrow X_n \) be the input zigzag filtration, where all arrows are forward or backward inclusions of a single cell. As previously, denote \( F_j \) by

\[
F_j : X_1 \xrightarrow{\sigma_1} X_2 \xrightarrow{\sigma_2} \cdots \xrightarrow{\sigma_j} X_{j+1} \xrightarrow{\sigma_{j+1}} \cdots X_{j+m-1} \xrightarrow{\sigma_m} X_{j+m} = \emptyset
\]

Passing from filtration \( F_j \) to filtration \( F_{j+1} \) using reflection and transposition diamonds consists of the following.

1. If \( X_j \xrightarrow{\sigma} X_{j+1} \) is forward in \( F \). Define \( F_{j+1} \) to be

\[
F_{j+1} : X_1 \xrightarrow{\sigma} X_2 \xrightarrow{\sigma} \cdots \xrightarrow{\sigma} X_{j} \xrightarrow{\sigma} X_{j+1} \xrightarrow{\sigma} X_{j+2} \xrightarrow{\sigma_2} \cdots \xrightarrow{\sigma_{j+1}} X_{j+m-1} \xrightarrow{\sigma_m} X_{j+m} = \emptyset
\]

Considering \( \overline{F}_j \) to be \( F_j \) with two extra identity arrows,

\[
\overline{F}_j : X_1 \leftarrow X_2 \leftarrow \cdots \xleftarrow{1} X_j \xleftarrow{1} X_j \xleftarrow{1} X_{j+1} \xleftarrow{1} X_{j+2} \xleftarrow{1} \cdots \xleftarrow{1} X_{j+m-1} \xleftarrow{1} X_{j+m} = \emptyset
\]

we have that \( \overline{F}_j \) and \( F_{j+1} \) are related by a reflection diamond (Diagram (11)) at \( X_j \). Studying the effect of a reflection diamond on homology, algorithm [32] updates a homology matrix at \( F_j \) (and also \( \overline{F}_j \)), into a homology matrix at \( F_{j+1} \), compatible with \( F_{j+1} \) defined above.

2. If \( X_j \xleftarrow{\sigma} X_{j+1} \) is backward in \( F \). There exists an index \( \ell \) such that \( \sigma = \sigma_{\ell} \) in the part \( F_j[j:j+m] \) of the filtration \( F_j \). Define \( F_{j+1} \) to be

\[
F_{j+1} : X_1 \xrightarrow{\sigma_{\ell} = \sigma} X_j \xrightarrow{\sigma_1} X_{j+1} \xrightarrow{\sigma_1} X_{j+2} \xrightarrow{\sigma_2} \cdots \xrightarrow{\sigma_{\ell-1}} X_{j+\ell-2} \xleftarrow{\sigma_1} X_{j+\ell-1} \xleftarrow{\sigma_\ell} X_{j+\ell} \xleftarrow{\sigma_{\ell+1}} \cdots = \emptyset
\]

where the removal of \( \sigma = \sigma_{\ell} \) has been moved all the way up to \( X_i \). This can be attained by applying successively transposition diamonds (Diagram (11)) in \( F_j[j:j+m] \), in order to obtain \( F_{j+1} \). Studying the effect of transposition diamonds on homology, algorithm [32] updates a homology matrix at \( X_j \), compatible with \( F_j \), into a homology matrix at \( X_{j+1} \), compatible with \( F_{j+1} \) defined above.
