WHEN DOES THE POSITIVE SEMIDEFINITENESS CONSTRAINT HELP IN LIFTING PROCEDURES∗

Michel X. Goemans† Levent Tunçel‡

January 27, 2022

Abstract

We study the lift-and-project procedures of Lovász and Schrijver for 0-1 integer programming problems. We prove that the procedure using the positive semidefiniteness constraint is not better than the one without it, in the worst case. Various examples are considered. We also provide geometric conditions characterizing when the positive semidefiniteness constraint does not help.

Keywords: Semidefinite lifting, semidefinite programming, lift-and-project, integer programming

1 Introduction

Lovász and Schrijver (1991) have proposed a very intriguing successive convex relaxation procedure for 0-1 integer programming problems. The procedure called \( N_+ \), to be defined shortly, when applied to a classical linear programming (LP) relaxation of the stable set problem (with only the edge and nonnegativity constraints) produces a relaxation for which many well-known inequalities are valid, including the odd hole, odd antihole, odd wheel, clique, and even the orthonormal representation inequalities of Grötschel, Lovász and Schrijver (1981). This implies that for many classes of graphs, including perfect (for which clique inequalities are sufficient) or t-perfect graphs (for which odd hole inequalities are sufficient), one can find the maximum stable set by using the \( N_+ \) procedure.

The \( N_+ \) procedure is a strengthening of another procedure, called \( N \), also introduced by Lovász and Schrijver. The main difference between the two procedures is that \( N_+ \) involves a positive semidefinite constraint. When applied to a linear programming relaxation, \( N \) will produce another (stronger) LP relaxation while \( N_+ \) will produce a semidefinite relaxation. For the stable set problem, Lovász and Schrijver have shown that the relaxation produced by \( N \) is much weaker than the one derived from \( N_+ \).

In general, it is however not clear in which situations the procedure \( N_+ \) is better or significantly better than \( N \); especially, when \( N \) and \( N_+ \) are applied iteratively. In this paper, we try to shed some light on this question. We generalize certain properties derived by Lovász and Schrijver. We also identify certain situations in which \( N \) produces the same relaxation as \( N_+ \). Several examples are discussed throughout the paper, including one in which the number of iterations of the \( N_+ \) procedure needed to derive the convex hull of 0-1 points is equal to the dimension of the space, hence resolving a question left open by Lovász and Schrijver.

In the next section, we review the lift-and-project procedures and their basic properties. Section 3 includes upper bounds on the number of major iterations required by such procedures. Section 4 discusses techniques to prove lower bounds on the number of major iterations required. Sections 5 and 6 include geometric properties and characterizations of the convex relaxations produced by the procedures.

2 Lovász-Schrijver procedures \( N \) and \( N_+ \)

First, we describe two lift-and-project procedures proposed by Lovász and Schrijver (1991) which produce tighter and tighter relaxations of the convex hull of 0-1 points in a convex set. In what follows, \( e_j \) is the \( j \)th unit vector and \( e \) is the vector of all ones. The sizes of \( e \) and \( e_j \) will be clear from the context. The cone generated by all 0-1 vectors \( x \in \mathbb{R}^{d+1} \) with \( x_0 = 1 \) is called \( Q \). Let \( K \subset Q \) denote a convex cone; for example, \( K \) could be a polyhedral cone obtained from a polytope \( P \) in \([0,1]^d \) via homogenization using a new variable \( x_0 \). That is, if

\[
P = \{ x \in \mathbb{R}^d : Ax \leq b, \ 0 \leq x \leq e \},
\]
EFFICIENCY OF LIFTING PROCEDURES

then

\[ K := \left\{ \left( \begin{array}{c} x_0 \\ x \end{array} \right) \in \mathbb{R}^{d+1} : Ax \leq x_0 b, \ 0 \leq x \leq x_0 e \right\}. \]

We are interested in determining (or approximating) \( K_I \), the cone generated by all 0-1 vectors of \( K \).

Let \( K^*, Q^* \) denote the dual cones of \( K \) and \( Q \) under the standard Euclidean inner-product, e.g.,

\[ K^* := \{ s \in \mathbb{R}^{d+1} : x^T s \geq 0, \ \forall x \in K \}. \]

\( S^{d+1} \) denotes the space of \((d + 1) \times (d + 1)\) symmetric matrices and \( S^{d+1}_+ \) denotes the cone of \((d + 1) \times (d + 1)\) symmetric, positive semidefinite matrices. For a matrix \( A \in S^{d+1} \), we denote its positive semidefiniteness by \( A \succeq 0 \). When we deal with the duals of convex cones in the space of \((d + 1) \times (d + 1)\) matrices (or in the subspace of the symmetric matrices), we always take the underlying inner-product to be the trace inner-product (or Frobenius inner-product): \( \langle A, B \rangle := Tr(A^T B) \).

Let \( \text{diag} : S^{d+1} \to \mathbb{R}^{d+1} \) denote the linear operator which maps a symmetric matrix to its diagonal. Then its adjoint \( \text{diag}^* : \mathbb{R}^{d+1} \to S^{d+1} \) is the linear operator \( \text{Diag}(\cdot) \) which maps a vector from \( \mathbb{R}^{d+1} \) to the diagonal matrix in \( S^{d+1} \) whose \((i, i)\)th component is the \( i \)th component of the original vector.

**Definition 2.1 (Lovász and Schrijver (1991))** A \((d + 1) \times (d + 1)\) symmetric matrix, \( Y \), with real entries is in \( M(K) \) if

(i) \( Ye_0 = \text{diag}(Y) \), and
(ii) \( u^T Y v \geq 0, \ \forall u \in Q^*, v \in K^* \).

Lovász and Schrijver note that condition (ii) of the above definition is equivalent to \( YQ^* \subseteq K \) (where \( YQ^* = \{ Yx : x \in Q^* \} \)), or: (ii)' \( Ye_i \in K \) for all \( i \in \{1, \ldots, d\} \) and \( Y(e_0 - e_i) \in K \) for all \( i \in \{1, \ldots, d\} \), since the extreme rays (after normalization) of the cone \( Q^* \) are given by \( \text{ext}(Q^*) = \{ e_1, e_2, \ldots, e_d, (e_0 - e_1), (e_0 - e_2), \ldots, (e_0 - e_d) \} \).

**Definition 2.2 (Lovász and Schrijver (1991))** \( Y \in M_+(K) \) if \( Y \in M(K) \) and \( Y \) is positive semidefinite.

Observe that if we take any \( x \in K \) (not necessarily integral) and consider \( Y = xx^T \), \( Y \) satisfies \( Y \succeq 0 \) and also (ii)' , but this specific \( Y \) satisfies (i) if and only if \( x \) is such that \( x_i(x_0 - x_i) = 0 \) for all \( i \), i.e. \( x \) corresponds to a 0-1 vector.
Now, we define the projections of these liftings $M$ and $M_+$:
\[
N(K) := \{\text{diag}(Y) : Y \in M(K)\},
\]
\[
N_+(K) := \{\text{diag}(Y) : Y \in M_+(K)\}.
\]

The above argument regarding $xx^T$ shows that $K_I \subseteq N_+(K) \subseteq N(K) \subseteq K$, the last inclusion following from the fact that $Y(e_0 - e_i) \in K$ and $Ye_i \in K$ imply that $x = Ye_0 \in K$.

If $P$ is a polytope (or any convex set) in $[0,1]^d$ then we simply write $N_+(P)$ to represent \[
\{x : \begin{pmatrix} 1 \\ x \end{pmatrix} \in N_+(K)\}
\]
where $K$ is the cone obtained via homogenization using the variable $x_0$, and similarly for $N(P)$. We also let $M(P) = M(K)$ and $M_+(P) = M_+(K)$.

We should point out that the definition of $M$ (or $M_+$) is such that $M(K)$ depends only on the sets $K \cap \{x : x_i = x_0\}$ and $K \cap \{x : x_i = 0\}$ for all $i$. In particular, we have:

**Lemma 2.1** Let $K$ and $K'$ be such that $K \cap \{x : x_i = x_0\} = K' \cap \{x : x_i = x_0\}$ and $K \cap \{x : x_i = 0\} = K' \cap \{x : x_i = 0\}$ for all $i \in \{1, \ldots, d\}$. Then $M(K) = M(K')$ (and $N(K) = N(K')$) and $M_+(K) = M_+(K')$ (and $N_+(K) = N_+(K')$).

For example, $P = \{x \in \mathbb{R}^2 : \|x - 0.5e\|_2 \leq \frac{1}{2}\}$ and $P' = \{x \in \mathbb{R}^2 : \|x - 0.5e\|_1 \leq 0.5\}$ (see Figure 1) have the same $N(P) = N(P')$.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1.png}
\caption{Two convex sets with the same $N_+(\cdot)$.}
\end{figure}

The definitions of $M$, $N$, $M_+$ and $N_+$ are invariant under various operations including flipping coordinates $x_i \rightarrow (1 - x_i)$ for any subset of the indices $\{1, 2, \ldots, d\}$. More formally,

**Proposition 2.2 (Lovász and Schrijver (1991))** Let $A$ be a linear transformation mapping $Q$ onto itself. Then
\[
N(AK) = AN(K) \quad \text{and} \quad N_+(AK) = AN_+(K).
\]
One crucial feature of the operators $N$ and $N+$ is that they can be iterated. The iterated operators $N^r(K)$ and $N^+_{r}(K)$ are defined as follows. $N^0(K) := K$, $N^1_{0}(K) := K$, $N^r(K) := N(N^{r-1}(K))$ and $N^+_{r}(K) := N_+(N^+_{r-1}(K))$ for all integers $r \geq 1$. Lovász and Schrijver (1991) show that, even without the positive semidefiniteness constraints, $d$ iterations are sufficient to get $K_I$:

**Theorem 2.3 (Lovász and Schrijver (1991))**

$$K \supseteq N(K) \supseteq N^2(K) \supseteq \ldots \supseteq N^d(K) = K_I$$

and

$$K \supseteq N_+(K) \supseteq N^2_+(K) \supseteq \ldots \supseteq N^d_+(K) = K_I.$$

Let $a^T x \leq \alpha x_0$ be a valid inequality for $K_I$. Then the smallest nonnegative integer $r$ such that $a^T x \leq \alpha x_0$ is valid for $N^r(K)$ is called the $N$-rank of $a^T x \leq \alpha x_0$ relative to $K$. The $N_+$-rank of $a^T x \leq \alpha x_0$ relative to $K$ is defined similarly. The above theorem states that these ranks are at most $d$ for any valid inequality. The $N$-rank (resp. $N_+$-rank) of a cone $K$ is the smallest nonnegative integer $r$ such that $N^r(K) = K_I$ (resp. $N^+_{r}(K) = K_I$).

Theorem 2.3 can also be proved using the results of Balas (1974), see Balas, Ceria and Cornuéjols (1993). Our interest, in this paper, mostly lies in understanding the strength of $N_+$ in comparison to $N$. Consider the stable set polytope on a graph $G = (V, E)$ defined as the convex hull of incidence vectors of sets of non-adjacent vertices (known as stable sets). Let $FRAC$ be the relaxation defined by the edge constraints ($x_i + x_j \leq 1$ for all edges $(i, j) \in E$) and the nonnegativity constraints ($x_i \geq 0$ for all $i \in V$). Then $N(FRAC)$ is exactly equal to the relaxation obtained by adding all odd hole inequalities, saying that $\sum_{i \in C} x_i \leq \frac{|C|-1}{2}$ for any odd cycle $C$ with no chords. However, many more complicated inequalities have small $N_+$-rank. Lovász and Schrijver (1991) prove that odd hole, odd antihole, odd wheel, clique and orthogonal inequalities all have $N_+$-rank at most 1, relative to $FRAC$. These results are proved using Lemma 3.3 of next section, except for the orthogonality constraints. In contrast, the $N$-rank of a clique inequality for example is equal to $p - 2$ where $p$ is the size of the clique. Note that the separation problem for the class of clique inequalities is NP-hard (and so is the problem of optimizing over the clique inequalities, see Grötschel, Lovász and Schrijver (1981)). $N_+$, however, leads to a polynomial-time separation algorithm for a broader class of inequalities. This, and more generally the importance of $N$ and $N_+$, stems from the following result.

**Theorem 2.4 (Lovász and Schrijver (1991))** If we have a weak separation oracle for $K$ then we have a weak separation oracle for $N^r(K)$ and $N^+_{r}(K)$ for any fixed constant $r$.

Together with the equivalence between (weak) optimization and (weak) separation (Grötschel et al. (1981)), this implies for example that the stable set problem can be solved in polynomial time for any graph with bounded $N_+$-rank (Lovász and Schrijver (1991)).

Next we study the upper bounds on $N$- and $N_+$-ranks of inequalities and convex sets.
3 Upper bounds on the $N$- and $N_+$-rank

Lovász and Schrijver give some ways to upper bound the $N$-rank of an inequality. They show the following.

**Lemma 3.1 (Lovász and Schrijver (1991))**

$$N_+(K) \subseteq N(K) \subseteq (K \cap \{x : x_i = 0\}) + (K \cap \{x : x_i = x_0\}), \text{ for all } i \in \{1, 2, \ldots, d\}.$$  

Lovász and Schrijver (1991) define an operator $N_0$ by:

$$N_0(K) = \bigcap_{i=1, \ldots, d} \{(K \cap \{x : x_i = 0\}) + (K \cap \{x : x_i = x_0\})\}.$$ 

Thus, $N(K) \subseteq N_0(K)$. The iterated operator $N_0^r$, $N_0$-rank of inequalities, polytopes and convex cones are defined analogously to the corresponding definitions of $N$- and $N_+$-ranks.

Lemma 3.2 shows that an inequality will be valid for $N(K)$ if it is valid for $K \cap \{x : x_i = 0\}$ and $K \cap \{x : x_i = x_0\}$ for some $i$. In order to iterate Lemma 3.2, we first need the following lemma. It is stated in terms of the faces of $Q$, which can be obtained by intersecting $Q$ with hyperplanes of the form $\{x : x_i = 0\}$ or $\{x : x_i = x_0\}$. Similar insights for a procedure related to the $N$- procedure were discussed by Balas (1974).

**Lemma 3.2** Let $F$ be any face of $Q$. Then

$$N(K \cap F) = N(K) \cap F.$$ 

Similarly for $N_+$ and $N_0$.

**Proof.** “$\subseteq$” is clear from the definitions. For the converse, let $x \in N(K) \cap F$. This means that there exists a matrix $Y \in M(K)$ with $Ye_0 = x$. Since $Ye_i \in K \subseteq Q$ and $Y(e_0 - e_i) \in K \subseteq Q$ and their sum $Ye_i + Y(e_0 - e_i) = Ye_0$ belongs to the face $F$ of $Q$, we have that $Ye_i$ and $Y(e_0 - e_i)$ must belong to $F$, by definition of a face. Thus, $Ye_i \in K \cap F$ and $Y(e_0 - e_i) \in K \cap F$ for all $i$ implying that $Y \in M(K \cap F)$ and $x \in N(K \cap F)$. The proof for $N_+$ is identical.  

Iterating Lemma 3.2, we get:

**Corollary 3.3** Let $F$ be any face of $Q$. Then, for any $r$,

$$N^r(K \cap F) = N^r(K) \cap F.$$ 

Similarly for $N_+$ and $N_0$.  

Repeatedly using Lemma \ref{lem:clone} and Lemma \ref{lem:clone2} (or Corollary \ref{cor:clone}), we can derive a condition that an inequality be valid for $N^r(K)$. This, in particular, proves Theorem \ref{thm:mass}.

**Theorem 3.4** $N^r_+(K) \subseteq N^r(K) \subseteq N^d_0(K) \subseteq \tilde{N}^r_0(K)$ where

$$\tilde{N}^r_0(K) = \bigcap_{\{J \subseteq \{1, \ldots, d\} : |J| = r\}} \left\{ (K \cap \{x : x_i = 0 \text{ for } i \in J_0 \text{ and } x_i = x_0 \text{ for } i \in J_1\}) \right\}.$$ 

We should point out that even though $N_0(K) = \tilde{N}_0(K)$ and $N^d_0(K) = N^d(K) = N^d_0(K) = \tilde{N}^d_0(K)$, $N^d_0(K)$ is not necessarily equal to $\tilde{N}^d_0(K)$, if $2 \leq r \leq (d - 1)$. For example, for $K = \{x \in Q : x_1 + x_2 + x_3 \leq 1.5x_0\}$, one can show that $(1, 0.5, 0.5, 0.5) \in (\tilde{N}^2_0(K) \setminus N^2_0(K)).$

For $N_+(K)$, Lovász and Schrijver (1991) give a different condition for the validity of an inequality. In the statement of the next lemma, the assumption that $a \geq 0$ is without loss of generality (by flipping coordinates if necessary, as shown in Proposition \ref{prop:flip}).

**Lemma 3.5 (Lovász and Schrijver (1991))** Let $a \geq 0$. Then $a^T x \leq \alpha x_0$ is valid for $(K \cap \{x : x_i = x_0\})$ for all $i$ such that $a_i > 0$, implies $a^T x \leq \alpha x_0$ is valid for $N_+(K)$.

As mentioned previously, the result that clique, odd hole, odd antihole, odd wheel inequalities for the stable set problem have $N_+$-rank 1 follows from the above lemma. For the stable set problem (as for many combinatorial optimization problems), there exists several important constructions to derive facet-defining valid inequalities from other facet-defining inequalities. The simplest is cloning a clique at a vertex $v$, which consists of replacing the vertex by a clique, replacing all the edges incident to $v$ by corresponding edges incident to all clique vertices and substituting in the inequality the variable for $v$ by the sum of the variables of the clique vertices. It can easily be shown that the resulting inequality is valid and facet-defining if the original inequality was a non-trivial (i.e. different from the nonnegativity constraints) facet-defining inequality. In general, it is not clear how cloning influences the $N_+$-rank of an inequality. However, if we perform cloning at the center vertex of an odd wheel inequality, Lemma \ref{lem:clone3} implies that the $N_+$-rank still remains equal to 1. If we perform cloning at one or several vertices of an odd wheel, odd hole or odd antihole inequality, Lemma \ref{lem:clone4} implies that the $N_+$-rank is at most 2. Indeed, if we fix any variable (of the corresponding subgraph) to 1, the resulting inequality can be seen to be a linear combination of clique inequalities and hence valid for $N_+(\text{FRAC}).$

Lemma \ref{lem:clone5} can be extended to derive conditions under which the $N_+$-rank of an inequality is at most $r$.

**Theorem 3.6** Let $a \geq 0$ and let $I_+ = \{i : a_i > 0\}$. If $a^T x \leq \alpha x_0$ is valid for $(K \cap \{x : x_i = x_0, \text{ for all } i \in I\})$ for all sets $I \subseteq I_+$ satisfying either of the following two conditions

[Equation]
1. $|I| = r$,
2. $|I| \leq (r - 1)$ and $\sum_{i \in I} a_i > \alpha$,

then $a^T x \leq \alpha x_0$ is valid for $N^r_+(K)$.

Observe, however, that the result mentioned previously regarding cloning does not follow from Theorem [3.6].

**Proof.** We proceed by induction on $r$. For $r = 1$, the result is Lemma [3.5].

Assume now that $r > 1$, that the theorem was proved for $(r-1)$ (and for any inequality and for any convex set $K$), and that the hypothesis is satisfied for the inequality $a^T x \leq \alpha x_0$ and $r$. From Corollary [3.3] and Lemma [3.4], we know that $a^T x \leq \alpha x_0$ is valid for $N^r_+(K) = N^r_+(N^{r-1}_+(K))$ if it is valid for $N^{r-1}_+(K) \cap \{x : x_i = x_0\} = N^{r-1}_+(K \cap \{x : x_i = x_0\})$ for all $i \in I_+$. This is equivalent to showing that $a^T x - a_i x_i \leq (\alpha - a_i) x_0$ is valid for $N^{r-1}_+(K \cap \{x : x_i = x_0\})$.

Now there are two cases. If $\alpha - a_i < 0$ then condition [2] implies that $K \cap \{x : x_i = x_0\} = \emptyset$ and thus any inequality is valid for $N^{r-1}_+(K \cap \{x : x_i = x_0\}) = \emptyset$. On the other hand, if $\alpha - a_i \geq 0$, we can use induction to prove the result. Indeed, conditions [2] and [3] for inequality $a^T x \leq \alpha x_0$ and $r$ imply that conditions [2] and [3] are satisfied for the inequality $a^T x - a_i x_i \leq (\alpha - a_i) x_0$ for $r - 1$. Thus, by the inductive hypothesis, $a^T x - a_i x_i \leq (\alpha - a_i) x_0$ is valid for $N^{r-1}_+(K \cap \{x : x_i = x_0\})$, proving the inductive statement. \hfill \blacksquare

For the stable set problem, the above theorem implies that the $N_+$-rank of a graph is at most its stability number $\alpha(G)$, the cardinality of the largest stable set in $G$; this was proved in Corollary 2.19 of Lovász and Schrijver (1991). More generally, if we consider a polytope $P$ for which $P_t$ is only described by inequalities of the form $a^T x \leq \alpha x_0$ with $a \geq 0$ (i.e. it is lower comprehensive, see Section [3]) then its $N_+$-rank is upper bounded by the maximum number of variables that can be set to 1 in $P$ to obtain a unique integral point of $P_t$ (in which the other variables are thus set to 0). Similar, more complex, statements can be made if the polytope is not lower comprehensive.

### 3.1 Example 1: Matching polytope

Consider the complete undirected graph on the vertex set $V$; let $E$ denote its edge set. Let

$$P := \{x \in \mathbb{R}^E : x(\delta(v)) \leq 1, \forall v \in V, \ 0 \leq x \leq e\}.$$

In the above, $\delta(v)$ is the set of edges in $E$ that are incident on $v$; for $S \subseteq E$, $x(S)$ represents $\sum_{j \in S} x_j$. For $S \subseteq V$, let $E(S)$ refer to the set of edges with both endpoints in $S$. Then the
matching polytope for the complete graph is
\[ P_I := \text{conv} \left\{ P \cap \{0, 1\}^E \right\}. \]
Edmonds (1965) proved that
\[ P_I = \left\{ x \in P : x(E(S)) \leq \frac{|S| - 1}{2} \text{ for all } S \subseteq V \text{ such that } |S| \text{ is odd} \right\}. \]
The above inequalities are known as the blossom inequalities.

**Theorem 3.7 (Stephen and Tunçel (1999))** The \( N_+ \)-rank of the inequality
\[ x(E(S)) \leq \frac{|S| - 1}{2} \]
with respect to \( P \) is \[ \frac{|S| - 1}{2}. \]

The fact that the \( N_+ \)-rank is at most \[ \frac{|S| - 1}{2} \]
also follows directly from Theorem 3.6. Observe that since \( d \) is \( |V|(|V| - 1)/2 \), we derive that the \( N_+ \)-rank of \( P \) is equal to \( (\sqrt{1 + 8d} - 1)/4 \) if \( |V| \) odd and, \( (\sqrt{1 + 8d} - 3)/4 \) if \( |V| \) even.

From Theorem 3.7, the \( N \)-rank of the blossom inequality on \( S \) is at least \( \frac{|S| - 1}{2} \). Furthermore, using Theorem 3.4 with \( J \) being the complement of a complete bipartite graph on \( \frac{|S| - 1}{2} \) and \( \frac{|S| + 1}{2} \) vertices on each side, we derive that the \( N_0 \)-rank of a blossom inequality is equal to \( \frac{(|S| - 1)^2}{4} \). This uses the fact that \( P \) is an integral polytope if and only if the underlying graph is bipartite. Thus, the \( N \)-rank is at most \( \frac{(|S| - 1)^2}{4} \). These bounds are to be compared with those derived from Corollary 2.8 of Lovász and Schrijver (1991) (since a matching in a graph can be viewed as a stable set in its line graph). Their results imply a lower bound of \( (|S| - 2) \) and an upper bound of \( \frac{1}{2}(|S| - 1)^2 - 1 \).

### 3.2 Example 2

Consider
\[ K := \left\{ \begin{pmatrix} x_0 \\ x \end{pmatrix} \in \mathbb{R}^{d+1} : x(S) \leq \frac{d}{2} x_0, \text{ for all } S \subseteq \{1, 2, \ldots, d\} \text{ such that } |S| = \frac{d}{2} + 1, 0 \leq x \leq x_0 e \right\}. \]
Then
\[ K_I = \left\{ \begin{pmatrix} x_0 \\ x \end{pmatrix} \in \mathbb{R}^{d+1} : \sum_{i=1}^{d} x_i \leq \frac{d}{2} x_0, 0 \leq x \leq x_0 e \right\}. \]

Theorem 3.4 implies that the \( N \)-rank of \( \sum_{i=1}^{d} x_i \leq \frac{d}{2} x_0 \) is at most \( (d - 2) \), while Theorem 3.6 implies that the \( N_+ \)-rank is at most \( \frac{d}{2} \). These bounds are actually attained and this is discussed in Section 1.2. We also show in that section that the positive semidefiniteness constraint does not help for many iterations.
4 Lower bounds on the $N$- or $N_+$-rank

In this section, we provide lower bounds on the $N$- and $N_+$-rank. We also show a situation in which the positive semidefiniteness constraints do not help at all and both the $N$-rank and the $N_+$-rank of a polytope is $d$.

We first provide a way to derive points in $N_+(P)$ in certain cases. For $x \in \mathbb{R}^d$ define

$$x^{(j)}_i := \begin{cases} x_i & \text{if } i \neq j; \\ 0 & \text{if } i = j. \end{cases}$$

So, $x^{(j)} = x - x_je_j$. Throughout this section, let $K = \left\{ \begin{pmatrix} \lambda x \\ \lambda x \end{pmatrix} : x \in P, \lambda \geq 0 \right\}$.

**Theorem 4.1** Let $\bar{x} \in P$ such that $x^{(j)}$ and $(\bar{x}^{(j)} + e_j) \in P$, for all $j$ such that $0 < \bar{x}_j < 1$.

Then $x \in N_+(P)$.

Simply stated, this result says that if we can replace any coordinate of $x$ (strictly between 0 and 1) by 0 and 1 and remain in $P$ then $x \in N_+(P)$.

**Proof.** We define

$$Y(x) := \begin{pmatrix} 1 \\ x \end{pmatrix} (1, x^T) + \text{Diag} \begin{pmatrix} 0 \\ x_1 - x_1^2 \\ x_2 - x_2^2 \\ \vdots \\ x_d - x_d^2 \end{pmatrix}.$$ 

By definition, $Y(\bar{x}) \in S^{d+1}$, $Y(\bar{x})e_0 = \text{diag}(Y(\bar{x})) = \begin{pmatrix} 1 \\ \bar{x} \end{pmatrix} \in K$. Moreover,

$$Y(\bar{x})e_j = \bar{x}_j \begin{pmatrix} 1 \\ \bar{x}^{(j)} + e_j \end{pmatrix}, \text{ for all } j \in \{1, 2, \ldots, d\};$$

therefore, $Y(\bar{x})e_j \in K$ for all $j \in \{1, 2, \ldots, d\}$. Similarly,

$$Y(\bar{x})(e_0 - e_j) = (1 - \bar{x}_j) \begin{pmatrix} 1 \\ \bar{x}^{(j)} \end{pmatrix}, \text{ for all } j \in \{1, 2, \ldots, d\};$$

therefore, $Y(\bar{x})(e_0 - e_j) \in K$ for all $j \in \{1, 2, \ldots, d\}$. Finally, since

$$\text{Diag} \begin{pmatrix} 0 \\ x_1 - x_1^2 \\ x_2 - x_2^2 \\ \vdots \\ x_d - x_d^2 \end{pmatrix} \succeq 0 \text{ and } \begin{pmatrix} 1 \\ x \end{pmatrix} (1, x^T) \succeq 0,$$
for all $0 \leq x \leq e$, we have $Y(\bar{x}) \succeq 0$. Therefore, $Y(\bar{x}) \in M_+(P)$ and $x \in N_+(P)$ as desired.

\begin{figure}[h]
\centering
\includegraphics[width=0.4\textwidth]{figure2.png}
\caption{Convex set satisfying the condition of Corollary 4.2.}
\end{figure}

As a corollary, we derive the following (see Figure 2 for an illustration).

**Corollary 4.2** Let $P$ be such that $(P \cap \{x : x_j = 0\}) + e = P \cap \{x : x_j = 1\}$ for all $j \in \{1, \cdots, d\}$. Then

\[ N_+(P) = N(P) = N_0(P) = \bigcap_{j \in \{1, \cdots, d\}} \{x : x^{(j)} \in P\}. \]

**Proof.** Let $C = \bigcap_{j \in \{1, \cdots, d\}} \{x : x^{(j)} \in P\}$. By Lemma 3.1, we know that $N_+(P) \subseteq N(P) \subseteq N_0(P) \subseteq C$. On the other hand, Theorem 4.1 shows that $C \subseteq N_+(P)$. 

In the proof of Theorem 4.1, we constructed a $Y \in M_+(P)$ such that a certain $x \in P$ would also be in $N_+(P)$. The idea of the proof suggests a stronger technique to achieve such a goal. We define

\[ Y(x) := \begin{pmatrix} 1 \\ x \end{pmatrix} (1, x^T) + \operatorname{Diag} \begin{pmatrix} 0 \\ x_1 - x_1^2 \\ \vdots \\ x_d - x_d^2 \end{pmatrix} + \begin{pmatrix} 0 & 0^T \\ B(x) \end{pmatrix}, \]

where $B(x) \in \mathcal{S}^d$, $\operatorname{diag}(B) = 0$. Then clearly we have $Y(x) \in \mathcal{S}^{d+1}$, $Y(x)e_0 = \operatorname{diag}(Y(x))$. Moreover, using the Schur complement of $(Y(x))_{00}$ in $Y(x)$, we have

\[ Y(x) \succeq 0 \iff B(x) + \operatorname{Diag} \begin{pmatrix} x_1 - x_1^2 \\ \vdots \\ x_d - x_d^2 \end{pmatrix} \succeq 0. \]
The latter can be assured in many simple ways, for example by diagonal dominance: It suffices to choose $B_{ij}$ such that

$$|B_{ij}| \leq \frac{1}{2} \min \left\{ \frac{x_i - x_i^2}{\# \text{ of nonzeros in column } i}, \frac{x_j - x_j^2}{\# \text{ of nonzeros in column } j} \right\}.$$ 

The entries of such a $B(x)$ will be further restricted by the condition $Y(x)e_i \in K$ for every $i \in \{1, 2, \ldots, d\}$ and $Y(x)(e_0 - e_i) \in K$ for every $i \in \{1, 2, \ldots, d\}$. If this condition is verified for some $B(x)$ then the above argument would imply $x \in N_+(P)$. In the case of Theorem 4.1, we utilized diagonal dominance; because of the special structure of $P$, we could choose $B(x) := 0$ and satisfy all the conditions for $x \in N_+(P)$.

### 4.1 Example 3: Infeasibility detection

We now give an example where both $N$ and $N_+$ require $d$ iterations, showing that Theorem 4.3 cannot be improved. This result was independently obtained by Cook and Dash (1999) who also show additional results regarding the rank of inequalities. Previously, the worse example known in terms the number of repeated $N_+$ iterations needed to obtain $K_I$ was the matching polytope results of Stephen and Tunçel (1999) where the $N_+$-rank was of the order of $\sqrt{d}$.

Let

$$P(p) := \left\{ x \in \mathbb{R}^d : \left\| x - \frac{1}{2} e \right\|_1 \leq \frac{p}{2} \right\}.$$ 

**Theorem 4.3** For $0 < p < d$, $N_+(P(p)) \supseteq P(p-1)$. Furthermore, $P(1) \neq \emptyset$ while $P_{1}(d-1) = \emptyset$. Thus, the $N_+$ procedure requires $d$ iterations to prove $P_{1}(d-1) = \emptyset$.

**Proof.** Follows from Corollary 4.2. (In fact this corollary characterizes precisely $N_+(P(p))$.)

One interesting feature of the example above is that $P(d-1)$ can be described by $2^d$ inequalities, contains no integer point, but no inequality can be removed without creating an integer point. This is actually an extreme situation in this regard as shown by the following result of Doignon (1973). Suppose we are given a set of $m$ linear inequalities

$$a_i^T x \leq b_i, \text{ for all } i \in J,$$

where $x \in \mathbb{R}^d$ and $|J| \geq 2^d$. A theorem of Doignon (1973) implies that if this system does not contain any integer points then there is a subsystem (of this system) with at most $2^d$ inequalities which does not have an integer solution. Doignon’s Theorem is an integer analog of Helly’s Theorem.
4.2 Example 2, continued

In Section 3.2, we have shown that the $N$-rank and the $N_+$-rank of

$$K := \left\{ \begin{pmatrix} x_0 \\ x \end{pmatrix} \in \mathbb{R}^{d+1} : x(S) \leq \frac{d}{2} x_0, \text{ for all } S \subset \{1,2,\ldots,d\} \text{ such that } |S| = \frac{d}{2} + 1, \ 0 \leq x \leq x_0 e \right\},$$

are at most $(d - 2)$ and $d/2$, respectively. Here we claim that these bounds are attained.

**Theorem 4.4** The $N$-rank of $\sum_{i=1}^d x_i \leq \frac{d}{2}$ relative to $K$ is $(d - 2)$. The $N_+$-rank of the same inequality relative to $K$ is $d/2$.

Moreover, for $r \leq \frac{d}{2} - \sqrt{d} + 3/2$, the optimum values of

$$\max\{e^T x : x \in N^r(K)\} \text{ and } \max\{e^T x : x \in N_+^r(K)\}$$

are the same.

Our proof of the first statement of the theorem, saying that the $N$-rank is $(d - 2)$ is lengthy and is not included here. The proof of the remainder of the theorem appears partly in this section and partly in the Appendix. The theorem indicates that the positive semidefiniteness constraint does not help for $(d/2 - o(d))$ iterations.

Unfortunately, neither Theorem 4.1 nor Corollary 4.2 is useful here. Instead, exploiting the symmetry (and convexity of $N(K)$ and $N_+(K)$), we will only consider points in $N^r(K)$ or $N_+^r(K)$ such that $x_i$ takes only three possible values, 0, 1 and a constant $\alpha$. Letting $n_0$ denote the number of $x_i$ set to 0 and letting $n_1$ denote the number of $x_i$ set to 1, we define $c(r, n_0, n_1)$ to be the largest common value $\alpha$ of the remaining $(d - n_0 - n_1)$ coordinates of $x$ such that $x \in N^r(K)$. We define $c_+(r, n_0, n_1)$ similarly with respect to $N_+^r(K)$.

By symmetry, such a point $x$ belongs to $N^r(K)$ (resp. to $N_+^r(K)$) if there exists a symmetric matrix $Y \in M(K)$ (resp. $Y \in M_+(K)$) of the form

$$Y(n_0, n_1; \alpha, \beta) := \begin{pmatrix}
1 & e^T & 0 & \alpha e^T \\
\alpha e & ee^T & 0 & eee^T \\
0 & 0 & 0 & 0 \\
\alpha e & eee^T & 0 & (\alpha - \beta)I + \beta ee^T
\end{pmatrix},$$

for some value $\beta$; here the columns of $Y$ are partitioned in the way that the first column corresponds to the homogenizing variable $x_0$, the next $n_1$ columns correspond to those $x_j$ that are set to one, the next $n_0$ columns correspond to those $x_j$ set to zero and the remaining $(d - n_0 - n_1)$ columns correspond to the remaining $x_j$’s (which are set to $\alpha$).

For $r = 0$ and $n_1 \leq d/2$, we see by plugging $x$ into the description of $K$ that

$$c(0, n_0, n_1) = c_+(0, n_0, n_1) = \begin{cases}
\frac{d/2 - n_1}{d/2 + 1 - n_1} & \text{if } n_0 \leq d/2 - 1, \\
1 & \text{otherwise.}
\end{cases}$$ (1)
For $r > 0$, the condition that $Y \in M^r(K)$ is equivalent to $\frac{\beta}{\alpha} \leq c(r-1,n_0,n_1+1)$ (corresponding to $Y e_i \in M^{r-1}(K)$) and $\frac{\alpha-\beta}{\alpha} \leq c(r-1,n_0+1,n_1)$ (corresponding to $Y(e_0-e_i) \in M^{r-1}(K)$). Eliminating $\beta$, we derive:

$$c(r,n_0,n_1) = \frac{c(r-1,n_0+1,n_1)}{1 - c(r-1,n_0,n_1+1) + c(r-1,n_0+1,n_1)}.$$ 

The condition that $Y \succeq 0$ reduces to (by taking a Schur complement) $(\alpha - \beta)I + (\beta - \alpha^2)ee^T \succeq 0$ (where the matrices have size $(d-n_0-n_1) \times (d-n_0-n_1)$, or $\alpha - \beta \geq 0$ and $\alpha - \beta + (d-n_0-n_1)(\beta - \alpha^2) \geq 0$. This can be seen to imply that

$$c_+(r,n_0,n_1) = \min \left( \frac{c_+(r-1,n_0+1,n_1)}{1 - c_+(r-1,n_0,n_1+1) + c_+(r-1,n_0+1,n_1)}, \frac{(d-n_0-n_1)c_+(r-1,n_0,n_1+1) + 1}{d - n_0 - n_1} \right).$$

Observe that the $N$-rank (resp. the $N_+$-rank) of $K$ is the smallest integer $r$ such that $c(r,0,0) = \frac{1}{2}$ (resp. $c_+(r,0,0) = \frac{1}{2}$). Theorem 4.4 hence follows from the following proposition.

**Proposition 4.5**

1. $c(d-3,0,0) = \begin{cases} \frac{1}{2} + \frac{1}{5d-6} & \text{if } d \text{ is even}, \\ \frac{1}{2} + \frac{1}{10d-20} & \text{if } d \text{ is odd}, \end{cases}$
2. $c_+(d/2 - 1,0,0) > 0.5$,
3. For any $r,n_0,n_1$ such that $r+n_0+n_1 \leq d/2 - \sqrt{d+3}/2$, we have $c(r,n_0,n_1) = c_+(r,n_0,n_1)$.

The proof of 1 is obtained by solving explicitly the recurrence for $c$; the details however, are omitted. The proof of the rest of the proposition is given in the Appendix.

Theorem $A.3$ in the Appendix actually illustrates a peculiar behavior of the $N_+$ operator (as well as the $N$ operator) on this example. In cutting plane procedures, it is usual that the improvement due to the addition of a cutting plane (or a batch of them) decreases as the algorithm progresses. However, Theorem $A.3$ shows that

$$\max\{e^T x : x \in N_+^r(K)\} = d c_+(r,0,0) > d \left( 1 - \frac{1}{d/2 + 1} \right).$$

Hence, as illustrated on Figure 3 for $d = 500$, the improvement in objective function value is negligible for many iterations and only towards the end increases considerably. We should point out, however, that the procedures $N$ and $N_+$ are such that the number of “important” inequalities generated in each iteration could potentially increase tremendously in later iterations.
5 Additional properties

A nonempty convex set $P \subseteq \mathbb{R}^d$ is called lower comprehensive if for every $x \in P$, every $y \in \mathbb{R}^d_+$ such that $y \leq x$ is also in $P$.

**Definition 5.1** Let $v \in \{0,1\}^d$. A convex set $P \subseteq [0,1]^d$ is said to be a convex corner with respect to $v$ if there exists a linear transformation $A$ of $\{0,1\}^d$ onto itself such that $Av = 0$ and $AP$ is lower comprehensive.

**Theorem 5.1** If $P$ is a convex corner with respect to $v \in \{0,1\}^d$ then so are $N(P)$ and $N_+(P)$.

**Proof.** By Proposition 2.3 and the definitions, it suffices to prove that if $P$ is lower comprehensive then so are $N(P)$ and $N_+(P)$. Let $P$ be lower comprehensive and $x \in N(P)$. It suffices to show that $(x - x_je_j) \in N(P)$ for every $j$ such that $x_j > 0$. Without loss of generality suppose $j = 1$ and $x_j > 0$. Then there exists $Y \in M(P)$ such that $Ye_0 = \begin{pmatrix} 1 \\ x \end{pmatrix}$. Let

$$Y_{ij} := \begin{cases} Y_{ij} & \text{if } i \neq 1 \text{ or } j \neq 1; \\
0 & \text{otherwise.} \end{cases}$$
Then using the fact that $P$ is lower comprehensive, it is easy to see that $\tilde{Y} \in M(P)$. Since the above argument applies to every $j$ such that $x_j > 0$, we proved that $N(P)$ is lower comprehensive.

We can prove that $N_+(P)$ is lower comprehensive by a very similar argument. We only have to note that if $Y \in M_+(P)$ then the corresponding $\tilde{Y}$ constructed as above will be positive semidefinite (in addition to satisfying $\tilde{Y}e_j \in K$ for every $j \in \{0, 1, 2, \ldots, d\}$ and $\tilde{Y}(e_0 - e_j) \in K$ for every $j \in \{1, 2, \ldots, d\}$) since every principal minor of $\tilde{Y}$ is a principal minor of $Y$ and $Y$ is positive semidefinite.

A similar fact, in a less general form, was observed independently by Cook and Dash (1999).

6 General conditions on the strength of the semidefinite constraint

In this section, we derive general conditions under which the positive semidefiniteness constraint is not useful. This can be expressed in several ways as

- $M(K) = M_+(K)$, or as
- $N(K) = N_+(K)$ or even as
- $\max\{c^T x : x \in N(K)\} = \max\{c^T x : x \in N_+(K)\}$ for some given $c$.

First, we rewrite condition (ii) of Definition 2.1. Since $Y$ is symmetric, $u^TYv \geq 0, \forall u \in Q^*, v \in K^* \iff u^TYv + v^TYu \geq 0, \forall u \in Q^*, v \in K^*$. Using the fact that $u^TYv + v^TYu = \text{Tr}(Y(uv^T + vu^T))$, we see that condition (ii) is also equivalent to

$$(ii)' Y \in [T(K)]^*,$$

where

$T(K) := \text{cone}\{uv^T + vu^T : u \in Q^*, v \in K^*\} = \text{cone}\{uv^T + vu^T : u \in \text{ext}(Q^*), v \in \text{ext}(K^*)\}.$

Let’s define

$D := \left\{ Y \in S_{d+1} : \text{diag}(Y) = Ye_0 \right\}.$

Note that the cone (more specifically, the subspace in this case) dual to $D$ in the space $S_{d+1}$ is the orthogonal complement of $D$.

$D^* = D^\perp = \left\{ \sum_{i=1}^{d} \alpha_i(E_{ii} - E_{0i}) : \alpha \in \mathbb{R}^d \right\},$

where $E_{ij} := e_ie_j^T + e_je_i^T$. We have
Theorem 6.1

\[ M_+(K) = M(K) \text{ if and only if } T(K) + D^\perp \supseteq S^{d+1}_+ . \]

Proof. By definition of the sets \( M(K), M_+(K) \), we have

\[ M(K) = M_+(K) \iff [T(K)]^* \cap D = [T(K)]^* \cap D \cap S^{d+1}_+. \]

Since the inclusion \([T(K)]^* \cap D \supseteq [T(K)]^* \cap D \cap S^{d+1}_+\) is clear, we have

\[ M(K) = M_+(K) \iff [T(K)]^* \cap D \subseteq S^{d+1}_+. \]

Noting that

\[ [T(K)]^* \cap D \subseteq S^{d+1}_+ \iff ([T(K)]^* \cap D)^* \supseteq S^{d+1}_+ , \]

(we used the fact that \( S^{d+1}_+ \) is self dual under the trace inner-product, in the space \( S^{d+1} \)) and

\[ ([T(K)]^* \cap D)^* = T(K) + D^* , \]

we conclude

\[ M(K) = M_+(K) \text{ if and only if } T(K) + D^\perp \supseteq S^{d+1}_+ . \]

This theorem completely characterizes when \( M \) and \( M_+ \) differ or are equal. To make the condition more easily tractable, we can give a more explicit description of \( T(K) + D^\perp \). Define \( F(K) \) to be set of all \( v = \left( \begin{array}{c} v_0 \\ \tilde{v} \end{array} \right) \in \mathbb{R}^{d+1} \) such that \(-\tilde{v}^T x \leq v_0 \) is a facet of \( P \) (or, more generally, for non-polyhedral convex sets, \( F(K) \) describes a set of valid inequalities exactly characterizing \( P \)). Note that \( F(K) \) can be taken as the set of extreme rays of \( K^* \). We arrive at the identity

\[ T(K) + D^\perp = \text{cone} \left\{ (e_i v^T + v e_i^T), \ i \in \{1, 2, \ldots, d\}, v \in F(K); \right. \]

\[ \left. [(e_0 - e_i) v^T + v(e_0 - e_i)^T], \ i \in \{1, 2, 3, \ldots, d\}, v \in F(K); \right. \]

\[ (E_{ii} - E_{0i}), \ i \in \{1, 2, \ldots, d\} \right\} \]

where we have used the fact that \( E_{0i} - E_{ii} \in T(K) \) since \( e_i \in F(K) \). So, \( M_+(K) = M(K) \) iff for every \( x \in \mathbb{R}^{d+1} \), we can express \( xx^T \) as an element of the above cone \((T(K) + D^\perp)\).

Consider the clique on four vertices and the corresponding LP relaxation \( FRAC \) of the stable set problem (with the edge and nonnegativity constraints only). For this example,

\[
Y := \begin{pmatrix}
1 & 1 & 1 & 1 & 1 \\
\frac{1}{3} & \frac{1}{3} & \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\
\frac{1}{3} & 0 & 0 & \frac{1}{3} & 0 \\
\frac{1}{3} & 0 & 0 & \frac{1}{3} & 0 \\
\frac{1}{3} & 0 & 0 & 0 & \frac{1}{3}
\end{pmatrix}
\in [T(K)]^* \cap D; \]
but clearly \( Y \not\in S_{+}^{d+1} \). A proof of this is provided by the incidence vector of the clique inequality on the four vertices:

\[
(e_0 - e_1 - e_2 - e_3 - e_4)^T Y (e_0 - e_1 - e_2 - e_3 - e_4) = \frac{1}{3}.
\]

This means, for \( x := (e_0 - e_1 - e_2 - e_3 - e_4) \), \( xx^T \) is not in the convex cone \( (T(K) + D^\perp) \).

Now, we relate these findings to \( N(K) \) and \( N_+(K) \).

**Corollary 6.2** If \( (T(K) + D^\perp) \supseteq S_{+}^{d+1} \), then \( N_r^+(K) = N^r(K) \) for every \( r \geq 0 \).

**Proof.** Trivial for \( r = 0 \). By Theorem 6.1, the assumption of the corollary implies \( N_+(K) = N(K) \). By Theorem 2.3, \( N(K) \subseteq K \). Thus,

\[
(T(N(K)) + D^\perp) \supseteq (T(K) + D^\perp) \supseteq S_{+}^{d+1}.
\]

Now, applying Theorem 6.1 recursively, we obtain the desired result. \( \blacksquare \)

Now we look at the weaker condition that \( N(K) = N_+(K) \).

**Theorem 6.3** \( N_+(K) = N(K) \) if and only if for every \( s \in \mathbb{R}^{d+1} \),

\[
\text{Diag}(s) \in T(K) + D^\perp + S_{+}^{d+1} \quad \text{implies} \quad \text{Diag}(s) \in T(K) + D^\perp.
\]

Before proceeding with the proof, observe that, for any convex cone \( K \subseteq S^{d+1} \), we have

\[
[\text{diag}(K)]^* = \left\{ s \in \mathbb{R}^{d+1} : \text{Diag}(s) \in K^* \right\}.
\]  \( (2) \)

**Proof.** As in the proof of Theorem 6.1, we obtain

\[
N(K) = N_+(K) \iff \text{diag } ([T(K)]^* \cap D) \subseteq \text{diag } ([T(K)]^* \cap D \cap S_{+}^{d+1}).
\]

Using equation (2) and the proof technique of Theorem 6.1, we find

\[
N(K) = N_+(K) \quad \text{if and only if}
\]

for every \( s \in \mathbb{R}^{d+1}, \text{Diag}(s) \in T(K) + D^\perp + S_{+}^{d+1} \quad \text{implies} \quad \text{Diag}(s) \in T(K) + D^\perp.
\]  \( \blacksquare \)
We should compare this result to Lemma 1.2 of Lovász and Schrijver (1991). Note that our result is also based on cone duality, we also characterize the dual cones of $N(K)$ and $N_+(K)$; but, we only work in the space of symmetric matrices instead of the larger space of all matrices. As a result, the dependence of the characterization on the skew symmetric matrices is eliminated and our description is more explicit.

Our ideas in the geometric characterizations above are also applicable in comparing the weaker procedure $N_0$ to $N$. Recall

$$N_0(K) := \bigcap_{i=1, \ldots, d} \{(K \cap \{x : x_i = 0\}) + (K \cap \{x : x_i = x_0\})\}. $$

We define

$$M_0(K) := \left\{ Y \in \mathbb{R}^{(d+1)\times(d+1)} : Ye_0 = Y^T e_0 = \text{diag}(Y), u^T Y v \geq 0, \forall u \in Q^*, v \in K^* \right\},$$

the main difference with $M$ is that $Y$ is not necessarily symmetric. As is mentioned by Lovász and Schrijver (1991), we have

$$N_0(K) = \{ Ye_0 : Y \in M_0(K) \}.$$

We further define

$$T_0(K) := \text{cone} \left\{ uv^T : u \in Q^*, v \in K^* \right\},$$

and

$$D_0 := \left\{ Y \in \mathbb{R}^{(d+1)\times(d+1)} : Ye_0 = Y^T e_0 = \text{diag}(Y) \right\}.$$

Then

$$Y \in M_0(K) \iff Y \in ([T_0(K)]^* \cap D_0),$$

where $[T_0(K)]^*$ is the dual of $T_0(K)$ in $\mathbb{R}^{(d+1)\times(d+1)}$ under the trace inner-product.

**Theorem 6.4** $M_0(K) = M(K)$ iff $([T_0(K)]^* \cap D_0) \supseteq \left\{ (e_i e_j^T - e_j e_i^T) : i, j \in \{1, 2, \ldots, d\} \right\}$.

**Proof.** As we showed, $M_0(K) = [T_0(K)]^* \cap D_0$ and it is clear from the definitions that $M(K) = [T_0(K)]^* \cap D_0 \cap S^{d+1}$. Note that

$$D_0^\perp = \text{span} \left\{ e_i e_i^T - e_0 e_i^T, e_i e_i^T - e_i e_0^T : i \in \{1, 2, \ldots, d\} \right\}.$$ 

Thus,

$$\pm (e_0 e_i^T - e_i e_0^T) \in \left( T_0(K) + D_0^\perp \right), \forall i \in \{1, 2, \ldots, d\}.$$

Let $\hat{S}^{d+1}$ denote the subspace of $(d+1) \times (d+1)$ skew-symmetric matrices with real entries. Therefore,

$$\left( T_0(K) + D_0^\perp \right) \supseteq \hat{S}^{d+1} \iff \left( T_0(K) + D_0^\perp \right) \supseteq \left\{ (e_i e_j^T - e_j e_i^T) : i, j \in \{1, 2, \ldots, d\} \right\}.$$
Now, using elementary cone geometry on closed convex cones and the definitions, we have the following string of equivalences:

\[
\left( T_0(K) + D_0^\perp \right) \supseteq \left\{ (e_i e_j^T - e_j e_i^T) : i, j \in \{1, 2, \ldots, d\} \right\} \quad \text{iff} \quad \left( T_0(K) + D_0^\perp \right) \supseteq \tilde{S}^{d+1} \\
\quad \text{iff} \quad [T_0(K)]^* \cap D_0 \subseteq S^{d+1} \\
\quad \text{iff} \quad M_0(K) = M(K). 
\]

\[ \square \]

**Corollary 6.5** If \( (T_0(K) + D_0^\perp) \supseteq \left\{ (e_i e_j^T - e_j e_i^T) : i, j \in \{1, 2, \ldots, d\} \right\} \) then \( N_0^r(K) = N^r(K) \) for every \( r \geq 0 \).

**Proof.** Trivial for \( r = 0 \). By Theorem 6.4, the assumption of the corollary implies \( N_0(K) = N(K) \). By Theorem 2.3, \( N(K) \subseteq K \). Thus,

\[
T_0(N(K)) \supseteq T_0(K) \supseteq \left\{ (e_i e_j^T - e_j e_i^T) : i, j \in \{1, 2, \ldots, d\} \right\}.
\]

Now, applying Theorem 6.4 recursively, we obtain the desired result. \[ \square \]

Let \( G \) denote the complete graph on \( d \) vertices, and consider the LP relaxation \( FRAC \) of the stable set problem on \( G \). For every \( i, j \in \{1, 2, \ldots, d\} \) such that \( i \neq j \), we have

\[
(e_0 - e_i - e_j) \in K^* \quad \text{and clearly} \quad e_i, e_j \in (K^* \cap Q^*).
\]

Thus, for every \( i, j \in \{1, 2, \ldots, d\} \) such that \( i \neq j \), we have

\[
e_i(e_0 - e_i - e_j)^T \quad \text{and} \quad e_j e_i^T \in T_0(K), \quad \text{and} \quad (e_i e_j^T - e_j e_i^T) \in D_0^\perp.
\]

This implies,

\[
\left( T_0(K) + D_0^\perp \right) \supseteq \left\{ (e_i e_j^T - e_j e_i^T) : i, j \in \{1, 2, \ldots, d\} \right\}.
\]

Therefore, the condition of Theorem 6.4 is satisfied and we have \( N_0^r(FRAC) = N^r(FRAC) \) for every \( r \geq 0 \).

As in Theorem 6.3, we obtain

**Corollary 6.6** \( N_0(K) = N(K) \) if and only if for every \( s \in \mathbb{R}^{d+1} \),

\[
\text{Diag}(s) \in T_0(K) + D_0^\perp + \tilde{S}^{d+1} \quad \text{implies} \quad \text{Diag}(s) \in T_0(K) + D_0^\perp.
\]
Instead of comparing $M(K)$ and $M_+(K)$, or $N(K)$ and $N_+(K)$, we might ask when are the set of optimal solutions of both relaxations the same. This is precisely when

$$[N(K)]^* + \left( \frac{-z^*}{c} \right) \supseteq [N_+(K)]^* + \left( \frac{-z^*}{c} \right),$$

where $z^*$ is the optimal value of $\max \left\{ c^T x : \begin{pmatrix} 1 \\ x \end{pmatrix} \in N(K) \right\}$.

Sometimes we are only interested in the bound provided by the relaxation. This is equivalent to finding the smallest $z$ for which $\begin{pmatrix} z \\ -c \end{pmatrix} \in [N(K)]^*$ and the smallest $z^+$ for which $\begin{pmatrix} z^+ \\ -c \end{pmatrix} \in [N_+(K)]^*$.

APPENDIX

In this appendix, we prove Proposition 4.5 and derive additional properties of \(c\) and \(c_+\). We first start with a few preliminary lemmas.

**Lemma A.1** Assuming \(0 \leq b < a \leq 1\) and \(p > 0\), we have

\[
a > \frac{a}{1 - b + a} > b,
\]

and

\[
a > \min \left( \frac{a}{1 - b + a}, \frac{(p - 1)b + 1}{p} \right) > b.
\]

**Proof.** First, \(a > \frac{a}{1 - b + a}\) follows from the fact that \(a > 0\) and \(a > b\), and this implies also that \(a > \min(\frac{a}{1 - b + a}, \frac{(p - 1)b + 1}{p})\).

On the other hand, we have that \(\frac{a}{1 - b + a} > b\) iff \(a > b - b^2 + ab\) iff \((a - b)(1 - b) > 0\), which follows by assumption. Furthermore, \(\frac{(p - 1)b + 1}{p} > b\) iff \((p - 1)b + 1 > pb\) iff \(1 > b\). As a result, both terms in the minimum are greater than \(b\), and the second part of each inequality follows.

This implies the following interlacing property.

**Corollary A.2** For any \(r \geq 1\) and any \(n_0, n_1 \leq \frac{d}{2} - r\), we have that

\[
c(r - 1, n_0, n_1 + 1) < c(r, n_0, n_1) < c(r - 1, n_0 + 1, n_1)
\]

and

\[
c_+(r - 1, n_0, n_1 + 1) < c_+(r, n_0, n_1) < c_+(r - 1, n_0 + 1, n_1).
\]

**Proof.** For \(r = 1\) and \(n_0, n_1 \leq \frac{d}{2} - 1\), we have that \(0 \leq f(r - 1, n_0, n_1 + 1) < f(r - 1, n_0 + 1, n_1) \leq 1\) where \(f = c_+\) by (I). Lemma A.1 now implies the result for \(r = 1\).

Proceeding by induction on \(r\) and assuming true the result for \(r - 1\), we derive that \(f(r - 1, n_0, n_1 + 1) < f(r - 2, n_0 + 1, n_1 + 1) < f(r - 1, n_0 + 1, n_1)\), which implies the result for \(r\) by Lemma A.1.

We can now get a lower bound on the coefficients \(c\) and \(c_+\).
Theorem A.3 For any \( r, n_0, n_1 \) such that \( s = r + n_0 + n_1 \leq d/2 \), we have that
\[
c(r, n_0, n_1) \geq c_+(r, n_0, n_1) > c(0, 0, s) = \frac{d/2 - s}{d/2 + 1 - s}.
\]

In particular, \( c_+(d/2 - 1, 0, 0) > 0.5 \).

This shows that the \( N_+ \)-rank of \( K \) is \( d/2 \).

Proof. For \( s \leq d/2 \), we have
\[
c(r, n_0, n_1) \geq c_+(r, n_0, n_1) > c_+(r, 0, n_0 + n_1) > c_+(0, 0, r + n_0 + n_1) = c(0, 0, s),
\]
where we have used Corollary A.2 twice.

Lemma A.4 Let \( 1 \geq a > b > c \geq 0 \) be such that \( a - b < b - c \). Then
\[
a - b < \frac{a}{1 - b + a} - \frac{b}{1 - c + b} < b - c.
\]

Proof. The first inequality is equivalent to
\[
b \left( \frac{1}{1 - c + b} - 1 \right) < a \left( \frac{1}{1 - b + a} - 1 \right).
\]
This inequality is satisfied since \( 0 < b < a \) and \( 0 < \frac{1}{1-c+b} - 1 < \frac{1}{1-b+a} - 1 \) (because \( 0 < a - b < b - c \)).

For the second inequality, we have that
\[
\left( \frac{b}{1 - c + b} - c \right) - \left( \frac{a}{1 - b + a} - b \right) = \frac{(b - c)(1 - c) - (a - b)(1 - b)}{1 - c + b} - \frac{(a - b)(1 - b)}{1 - b + a}.
\]
Moreover, we know that \( 1 - c > 1 - b > 0 \) and \( (b - c)/(1 - c + b) > (a - b)/(1 - b + a) > 0 \) since \( 0 < a - b < b - c \). Multiplying these two inequalities together, we get the desired inequality.

This implies that the coefficients \( c(r, n_0, n_1) \) also satisfy the following differential interlacing property.

Corollary A.5 For any \( r \geq 1 \), any \( 0 \leq n_0 \leq d/2 - r - 2 \), any \( 1 \leq n_1 \leq d/2 - r \), we have that
\[
c(r - 1, n_0 + 2, n_1 - 1) - c(r - 1, n_0 + 1, n_1) \quad < \quad c(r, n_0 + 1, n_1 - 1) - c(r, n_0, n_1)
\]
\[
< \quad c(r - 1, n_0 + 1, n_1) - c(r - 1, n_0, n_1 + 1).
\]
Proof. For \( r = 1 \), \( 1 \leq n_1 \leq \frac{d}{2} - 1 \) and \( n_0 \leq d/2 - 3 \), let \( a = c(r - 1, n_0 + 2, n_1 - 1) \), \( b = c(r - 1, n_0 + 1, n_1) \) and \( c = c(r - 1, n_0, n_1 + 1) \). Observe that \( a = 1 - \frac{1}{d/2+n_1} \), \( b = 1 - \frac{1}{d/2+1-n_1} \) and \( c = 1 - \frac{1}{d/2-n_1} \), implying that \( a > b > c \) as above, we know from Corollary A.2 that \( r \geq 1 \) result for \( r = 1 \). This implies that \( a > b > c \) and \( a - b < b - c \). Thus, Lemma A.4 implies the result for \( r = 1 \).

We now proceed by induction and assume the result true for \( r - 1 \geq 1 \). Defining \( a, b \) and \( c \) as above, we know from Corollary A.2 that \( a > b > c \) and from the inductive hypothesis that \( a - b < c(r - 2, n_0 + 2, n_1) - c(r - 2, n_0 + 1, n_1 + 1) < b - c \). Lemma A.4 then implies the result for \( r \).

Using Corollary A.5 repeatedly, we derive the following corollary.

**Corollary A.6** For any \( r \geq 1, n_0, n_1 \geq 0 \) such that \( s = r + n_0 + n_1 \leq d/2 \), we have that
\[
c(r - 1, n_0 + 1, n_1) - c(r - 1, n_0, n_1 + 1) < c(0, 1, s - 1) - c(0, 0, s) = \frac{1}{(d/2 + 1 - s)(d/2 + 2 - s)}.
\]

Proof. Using Corollary A.5, we derive
\[
c(r - 1, n_0 + 1, n_1) - c(r - 1, n_0, n_1 + 1) < c(r - 1, 1, n_0 + n_1) - c(r - 1, 0, n_0 + n_1 + 1) < c(0, 1, s - 1) - c(0, 0, s).
\]

**Theorem A.7** For any \( r, n_0, n_1 \geq 0 \) such that \( s = r + n_0 + n_1 \leq d/2 - \sqrt{d} + 3/2 \), we have that \( c(r, n_0, n_1) = c_+(r, n_0, n_1) \).

Proof. The proof is by induction on \( r \). The base case is obvious. Assume the result is true for \( r - 1 \). This implies that \( c(r - 1, n_0 + 1, n_1) = c_+(r - 1, n_0 + 1, n_1) \) and \( c(r - 1, n_0, n_1 + 1) = c_+(r - 1, n_0, n_1 + 1) \); we denote respectively by \( a \) and \( b \) these two quantities. The result would then follow if we can show that
\[
\frac{a}{1 - b + a} \leq \frac{(p - 1)b + 1}{p},
\]
where \( p = d - n_0 - n_1 \). This inequality is equivalent to \( pa \leq 1 - b + a + (p - 1)b - (p - 1)b^2 + (p - 1)ab \), or to \( (1 - b)(a - b)(p - 1) \leq 1 - b \). Since \( b \leq 1 \), we need to prove that \( a - b \leq \frac{1}{p - 1} = \frac{1}{d - n_0 - n_1 - 1} \). This follows from Corollary A.6 since we have that \( a - b < \frac{1}{(d/2 + 1 - s)(d/2 + 2 - s)} \leq \frac{1}{(\sqrt{d} - 0.5)(\sqrt{d} + 0.5)} < \frac{1}{d - n_0 - n_1 - 1} \).
