INTRODUCTION

Whereas venous thromboembolism (VTE) is a frequent clinical event in patients with cervical cancer, nonbacterial thrombotic endocarditis (NBTE), formerly known as marantic endocarditis, has rarely been described associated with gynecological malignancy and, in most of the cases, the diagnosis was confirmed postmortem. NBTE is considered as a manifestation of an overall prothrombotic state characterized by valve associated masses consisting of platelets and fibrin in absence of bacteria and without inflammatory destruction of the heart valves.

CASE REPORT

We report a case of NBTE of all heart valves and the atrial septum in a patient suffering from clear cell cervical cancer resulting in fatal venous and arterial thromboembolic events.
referring hospital. ECG showed no evidence of atrial fibrillation supporting cardioembolic events. A transesophageal echocardiography was performed and vegetations adherent to the in-situ port catheter and the aortic valve were found. An acute infective endocarditis was suspected and empiric antibacterial treatment with ampicillin and gentamicin was initiated. Because of respiratory distress, a computed tomography scan of the pulmonary arteries was performed, which revealed bilateral pulmonary embolism. Thereupon, the patient was referred to our tertiary care hospital for further therapy.

Medical history revealed that the patient had clear cell carcinoma of the cervix at an advanced stage (FIGO IV4A). The carcinoma had been diagnosed 1 year ahead of the current admission and initially treated with lymphadenectomy, and concurrent platinum-containing radiochemotherapy. With recently identified lymphogenic progression, therapy with Navelbine had been initiated. In addition, the patient had a history of pulmonary embolism in November 2020 since then followed by oral treatment with the direct factor Xa inhibitor Edoxaban for therapeutic anticoagulation.

On admission to our unit, the patient presented with severe hemodynamic instability reflected by tachycardia and hypotension. Respiratory distress required high flow oxygen support (10 L/min) via facial mask. The patient had no fever. Laboratory findings showed moderately elevated C-reactive protein (137 mg/L), normal procalcitonin (0.5 ng/ml) and normal leucocyte counts (9.43/µl). Moreover, we detected mild thrombocytopenia (115/µl), anemia (serum hemoglobin 7.3 g/dl), and highly elevated d-dimers (15 mg/L). Notably, Troponin I (11,462 pg/ml) and BNP (2624 pg/ml) were as well elevated (Table 1 for relevant laboratory findings on admission).

Bedside transthoracic echocardiography on admission suggested large vegetations affecting the aortic valve, so we performed an urgent transesophageal echocardiography. Consistent with the earlier examination, we found large vegetations, not only on the aortic valve (Figure 1) but also affecting the mitral (Figure 2A,B) and the tricuspid valve (Figure 2C) with large floating masses within the right ventricle extending over the pulmonary valve into the pulmonary artery (Figure 2D). Notably, although the vegetations were very pronounced, there was no destruction of the valves and only moderate insufficiencies could be visualized (Figure 1B and 2B,C). We also detected vegetations adherent to the right side of the atrial septum (Figure 3) and impaired systolic function of the left ventricle.

We initiated microbiological diagnostics by taking three pairs of blood cultures as well as next generation sequencing (NGS)-based diagnostics for pathogen identification (Cell-free DNA was analyzed with Noscoendo’s CE-IVD marked DISQVER assay) and extended the antibiotic therapy by Flucloxacillin according to guidelines for IE. Given the malignant underlying disease and the low values of PCT, we additionally started therapeutic anticoagulation with unfractionated heparin and performed extended thrombophilia and coagulation diagnostics (Table 2).

After multidisciplinary discussion of the case, the experts jointly determined that surgical intervention was not recommended. Following circulatory deterioration, the patient died on our ICU due to shock-associated multiple organ failure only 2 days later.

| TABLE 1 Laboratory findings on admission. |
|-----------------------------------------|
| Test            | Result | Reference Interval | Units |
|-----------------|--------|--------------------|-------|
| Creatinine      | 2.28   | 0.55–1.02          | mg/dl |
| eGFR            | 24     | 50–98              | ml/min/… |
| LDH             | 750    | <245               | U/L   |
| CK              | 366    | 30–170             | U/L   |
| Troponin I      | 11,462 | <24                | pg/ml |
| BNP             | 2624   | <100               | pg/ml |
| CRP             | 137    | <5                 | mg/l  |
| Procalcitonin   | 0.5    | <0.5               | ng/ml |
| D-Dimer         | 15.04  | <0.5               | mg/1 FEU |
| CA-125          | 4217   | <35                | U/ml  |
| Leucocytes      | 9.43   | 3.5–10             | per nl |
| Red blood cells | 2.8    | 3.7–4.8            | per pl |
| Hemoglobin      | 7.3    | 12–16              | g/dl  |
| Platelets       | 115    | 150–360            | per nl |

Abbreviations: BNP, brain natriuretic peptide; CK, creatine kinase; CRP, C-reactive protein; eGFR, estimated glomerular filtration rate; LDH, lactate-dehydrogenase.

3 | DISCUSSION

Nonbacterial thrombotic endocarditis (NBTE) is a rare clinical finding and is likely underdiagnosed, although it is a serious manifestation of cancer-related hypercoagulability and a potentially life-threatening source of thromboembolism. NBTE was first described by Ziegler in 1888 as fibrinous efflorescence on heart valves. In 1936, the term was renamed “nonbacterial thrombotic endocarditis” by Gross and Friedberg and defined as deposition of fibrin and platelets on heart valves without evidence of microorganisms. Most cases of NBTE are detected postmortem, and autopsy reports indicate an incidence of 1.2%. Anatomically, the aortic valve is most commonly affected, followed by the mitral valve. Pulmonary and tricuspid valves are rarely affected. Since NBTE is a rare finding, multivalvular NBTE is even rarer and quadrivalvular NBTE is a real rarity with very few published cases.
The premortem diagnosis of NBTE is usually made on the basis of clinical and echocardiographic findings in conjunction with exclusion of an infectious cause of endocarditis. Because an autopsy (required by German law) was refused by the family, our diagnosis was also based on echocardiographic imaging after interdisciplinary discussion.
discussion and after negative results of microbiologic di-
gnostics. This is a major limitation of our report as we
cannot provide a pathological evaluation of the vegeta-
tions. All of our conventional blood cultures and blood
culture-negative endocarditis (BCNE)- diagnostics (detect-
ing Bartonella henselaeae, Coxiella burnetii, Mycoplasma
pneumoniae, Legionella pneumophila, and Tropheryma
whipplei) as well as beta-D glucan remained negative. In
addition, we used commercially available next generation
sequencing (NGS)- based diagnostics for pathogen identi-
fication (Noscendo DISQVER®) that can detect bacteria,
DNA viruses, fungi, and parasites in a single assay.12 This
highly sensitive assay also showed no evidence of a bacte-
rial or fungal pathogen, so we are confident in diagnosing
NBTE in our patient.

Regarding differential diagnoses, cardiac metastasis is
also a very rare disease13 and involvement of heart valves
is an uncommon site for manifestation.14 Evidence of cer-
vical cancer metastasizing to the heart is available from
several case reports in recent decades, but none involved
the heart valves which makes the diagnosis very unlikely.

In a prospective study, NBTE was significantly more
common in cancer patients.15 Among gynecologic malign-
nancies, ovarian cancer is the most common cancer asso-
ciated with NBTE.16 To our knowledge, neither a case of
NBTE in a patient with clear cell cervical cancer nor a case
of quadrivalvular NBTE in any gynecologic malignancy
has been published so far.

Disseminated intravascular coagulation (DIC) can
be detected in most NBTE patients,5 indicating a poor
prognosis overall. We would like to emphasize that in
our case, NBTE developed in spite of pre-existing antico-
gulation. Our patient did not meet the criteria for DIC
based on the Overt DIC-score by the International Society
for Thrombosis and Hemostasis17 consisting of low
platelet count, elevated levels of a fibrin-related marker,
prolonged prothrombin time and decreased fibrinogen
levels. Nevertheless, we found high levels of D-Dimers
and thrombin-antithrombin complexes (TAT). The pres-
ence of TAT indicates ongoing, intravascular thrombin
formation as well as the consumption of antithrombin
and is associated with DIC.18

In addition, the patient showed severe venous and
arterial thromboses. Thus, on the one hand, the stroke
was likely caused by arterial thrombosis resulting from
dislocated thrombotic material from the NBTE of the
aortic valve. The occurrence of stroke is a disastrous
prognostic sign in NBTE patients with a 6-month mor-
tality of 80%.19 On the other hand, the acute pulmonary
embolism can well be attributed to emboli from the
marked thrombotic masses in the area of the tricuspid
and pulmonary valves.
4  |  CONCLUSION

To our best knowledge, we report the first case of a quadrivalvular nonbacterial endocarditis in a patient with a clear cell cervical cancer.

AUTHOR CONTRIBUTIONS
VG involved in imaging and drafting of the article; FG took the medical history of the patient; SD advised on imaging; FH, MV, TM, and IS critically revised the article; JW involved in imaging, concept, and drafting of the article.

ACKNOWLEDGEMENT
None.

FUNDING INFORMATION
JW received funding by the Boehringer Ingelheim Foundation “Novel and neglected cardiovascular risk factors: molecular mechanisms and therapeutic implications”, by the German Federal Ministry for Education and Research (BMBF EDU-V24), by the University of Mainz (‘Inneruniversitäre Forschungsförderung’) and by the German Interdisciplinary Association for Intensive Care and Emergency Medicine (‘DIVI Research Fellowship’).

CONFLICT OF INTEREST
The authors report no conflict of interests.

DATA AVAILABILITY STATEMENT
All data are included in the manuscript.

CONSENT
Written informed consent was obtained from the patient to publish this report in accordance with the journal’s patient consent policy.
