ABSTRACT

Objective(s): We investigated the relationship between the expression of tumor necrosis factor-inducible gene 6 (TSG-6) with inflammation and integrity of the bladder epithelium in the bladder tissues of patients with bladder pain syndrome/interstitial cystitis (BPS/IC) and the mechanism of action using a rat model of BPS/IC.

Materials and Methods: Expression of TSG-6 and uroplakin III was determined by immunohistochemistry of bladder biopsy samples from control human subjects and patients with verified BPS/IC. Our rat model of BPS/IC was employed to measure the perfusion of bladders with hyaluronidase, and assessment of the effect of TSG-6 administration on disease progression. Treatment effects were assessed by measurement of metabolic characteristics, RT-PCR of TGR-6 and interleukin6, bladder histomorphology, and immunohistochemistry of TGR-6 and uroplakin III.

Results: The bladders of patients with BPS/IC had lower expression of uroplakin III and higher expression of TSG-6 than controls. Rats treated with hyaluronidase for 1 week developed the typical signs and symptoms of BPS/IC, and rats treated with hyaluronidase for 4 weeks had more serious disease. Administration of TSG-6 reversed the effects of hyaluronidase and protected against disease progression.

Conclusion: Our results indicate that TSG-6 plays an important role in maintaining the integrity of the bladder epithelial barrier.

Introduction

Bladder pain syndrome/interstitial cystitis (BPS/IC) is a chronic inflammatory disease of the bladder that causes pain and discomfort, and is more common in females (prevalence: 2.7%) than males (prevalence 1.3%) (1). The pathogenesis of BPS/IC is unclear; however, potential causes of BPS/IC include infection, increased epithelial permeability, autoimmune disease, and neurogenic inflammation (2), and these can lead to chronic bladder inflammation, infiltration of mononuclear inflammatory cells and mast cells, release of inflammatory mediators, and ultimately bladder fibrosis (3). The main treatments include dietary control, oral medications, and intravesical surgery. Although intravesical heparin, hyaluronic acid (HA), and lidocaine are the main treatments, these methods generally have poor efficacy (4-9). Thus, it is important to establish new and effective treatments for BPS/IC (3, 10).

Uroplakin III and the glycosaminoglycan (GAG) layer of the bladder epithelium form a protective barrier that prevents entry of toxic substances in healthy subjects, but not in those with BPS/IC (1, 2, 11, 12). Thus, disruption of uroplakin III expression may indicate disrupted integrity of the bladder barrier (13, 14). Lee et al. (15) first identified tumor necrosis factor-inducible gene 6 protein (TSG-6) by screening a cDNA library of skin fibroblasts incubated with tumor necrosis factor-α (TNF-α). TSG-6 is a 35-kDa secreted glycoprotein, which has a LINK domain that binds to hyaluronic, and a complement C1r/C1s, Uegf, Bmp1 (CUB) domain that may mediate interactions with other proteins or carbohydrates (15). Numerous cell types (chondrocytes, synovial cells, and vascular smooth muscle cells) secrete TSG-6 upon exposure to pro-inflammatory cytokines, such as TNF-α and interleukin-1 (IL-1). TSG-6 is expressed in diverse inflammatory conditions, including osteoarthritis, inflammatory bowel disease, systemic lupus erythematosus, bacterial abscess, keratitis, myocardial infarction, and cerebral ischemia (16-19). Other research indicates that TSG-6 has significant protective and anti-inflammatory effects (20). In particular, TSG-6 contributes to remodeling of the extracellular matrix (ECM), synthesis of HA (21), and repair of defective bone and articular cartilage (22).

Recent research has highlighted the important role
of TSG-6 as a protein with anti-inflammatory and tissue-protective effects (21, 23). In particular, activation of mesenchymal stem cells leads to production of TSG-6, and this reduces signaling through the Toll-like receptor 2/Nuclear factor κB (TLR2/NF-κB) pathway (21, 24). Other research indicated that injection of recombinant TSG-6 stabilized retinal lesions in a murine model of macular degeneration (25), and that TSG-6 counteracted the matrix metalloproteinase-mediated proteolytic degradation in conjunctivochalasis (26). Moreover, TSG-6 has potential therapeutic value in treatment of other inflammatory disorders (27-29).

The documented therapeutic and anti-inflammatory effects of TSG-6 led us to hypothesize that injection of TSG-6 may promote repair of the bladder epithelial barrier in BPS/IC. Thus, this study investigated the expression of TSG-6 and uroplakin III in the bladder tissues of control human subjects and those with BPS/IC, and examined the mechanism of TSG-6 action in an animal model of BPS/IC.

Materials and Methods

Clinical study

All clinical procedures were approved by the Institutional Review Board of the First Affiliated Hospital of Fujian Medical University, China. Thirteen patients with IC were recruited into the patient group, with diagnosis based on previously described criteria (30), and 8 patients without cystitis or lower urinary tract symptoms were recruited into the control group. Bladder biopsies were performed with a cystoscope, and the bladder tissues were fixed in 10% neutral formalin for 24 hr, embedded in paraffin, and then subjected to immunofluorescence staining.

Animal model of BPS/IC

All animal experiments were approved by the Institutional Animal Care and Use Committee of the First Affiliated Hospital of Fujian Medical University. Forty-two healthy adult female Sprague-Dawley rats (250-300 gram) were used. The rats’ bladders were perfused with hyaluronidase (HAase) to establish the BPS/IC model (12), and animals were then anesthetized with isoflurane/oxygen (5% isoflurane for induction, 2% isoflurane for maintenance). Rats were then divided into 6 groups, with 6 rats per group: (i) the Control 1W group received bladder perfusion with 0.5 ml of normal saline (NS) once every 2 days for 1 week; (ii) the Control 4W group received bladder perfusion with NS for 4 weeks; (iii) the HAase 1W group were catheterized with PE50 tubes and received bladder perfusion with 4 mg/ml HAase (0.5 ml) for 30 minutes once every 2 days for 1 week; (iv) the HAase 4W group received bladder perfusion with HAase for 4 weeks; (v) the HAase 1W/TSF-6 group received TSG-6 (100 μg in 0.1 ml, from R&D Systems, Minneapolis MS, USA) and the HAase treatment for 1 week (Lee at al. 2009); and (vi) the HAase 1W/PBS group received phosphate-buffered saline (PBS) (instead of TSG-6) with the HAase treatment for 1 week. TSG-6 and PBS were injected via the tail veins at 6 hr after bladder perfusion with HAase, and injections were performed once every two days for 1 week. At 48 hr after the last treatment, animals were sacrificed for further analysis.

Measurement of rat metabolism

Rat metabolism was measured as previously described (31). In brief, rats in each group were placed into metabolic cages that were connected to a sensor and a computer, and were given ad libitum access to water and food. The urination frequency and total urine volume were recorded every 24 hr.

Histological examination

After sacrifice, rat bladders were collected and divided into two parts along the longitudinal axis. One part was stored at -80 °C and processed for RT-PCR and the other part was fixed in 10% neutral formalin for 48 hr. Tissues were fixed in paraffin and cut into 5-mm transverse sections (3 sections per animal), followed by hematoxylin and eosin (H&E) staining. Five fields were randomly selected from each section for analysis.

The inflammation score and number of inflammatory cells per field were assessed as previously described (2). In brief, bladder inflammation was assessed using a 4-point scoring system (0, morphologically unremarkable with no or minimal inflammation or epithelial changes; 1, mild inflammatory infiltrate within the lamina propria with scattered lymphocytes or monocytes, accompanied by mild chronic edema, hemorrhage or urothelial changes [altered epithelial thickness]; 2, moderate inflammatory infiltrate in the lamina propria and focal extension of the inflammation into the muscularis propria, accompanied by moderate chronic edema, hemorrhage, fibrin deposition or urothelial changes; 3, severe inflammation in the lamina propria and muscularis propria in association with other significant findings, such as urothelial ulceration, severe chronic edema, hemorrhage, and fibrin deposition).

RT-PCR

Total RNA was extracted from the bladder tissue with TRIzol® reagent (Takara, Otsu, Shiga, Japan) according to the manufacturer’s instructions, reverse transcribed into cDNA, and then synthesized by reverse transcription (Fermentas, Waltham, MA, USA). The primers used for RT-PCR were as follows: TSG-6, AAGCAGCCAGAAATGTGGA (forward), TCGGG-TGTGATAAGATG (reverse); IL-6, TCTGTCGTAGCCACCAGGA (forward), GCCCGAAAGAACACTGCTGG (reverse); GAPDH, GACGGTGAAAGCTGAGAAC (forward), TGGTGAAGCCGACTG (reverse). The expression of TSG-6 and IL-6 mRNAs is reported relative to that of GAPDH, as calculated by the 2-ΔΔCT method.
Enzyme-linked immunosorbent assay

The IL-6 level in the bladder tissue was measured by ELISA according to manufacturer's instructions (R&D Systems, Minneapolis, MN, USA). The reported level of IL-6 was normalized to the fresh weight of bladder tissue.

Immunofluorescence staining of the bladder

Immunofluorescence staining was performed with a standard two-step method. An uroplakin III polyclonal antibody (1:50), a TSG-6 polyclonal antibody (1:50) (Santa Cruz Biotechnology, CA, USA), an Alexa Fluor® 594 conjugated rabbit secondary antibody (1:200), and the ChemMate Envision+ Detection Kit (DakoCytomation, Dako, Denmark) were used for these experiments. DAPI-positive cells (blue), uroplakin III-positive positive cells (red), and TSG-6 positive cells (green) were observed under a fluorescence microscope within 2 hr, and representative photographs are shown. Image-Pro Plus 6.0 was used to determine the distribution and expression of these proteins, and expression was given as integrated optical density (IOD).

Statistical analysis

Continuous variables are presented as medians and inter-quartile ranges (IQRs). The Mann-Whitney U test was used to compare 2 groups, and the Kruskal-Wallis test was used to compare more than 2 groups. For post hoc analysis, the Mann-Whitney test with the Bonferroni correction was used for multiple comparisons. Statistical analyses were performed with IBM SPSS statistical software version 22 for Windows (IBM Corp., Amonk, NY, USA). A two-tailed P-value less than 0.05 indicated statistical significance.

Table 1. Expression of uroplakin III and tumor necrosis factor-inducible gene 6 (TSG-6) based on immunohistochemical analysis and integrated optical density (IOD) of bladder biopsies from control human subjects and those with bladder pain syndrome/interstitial cystitis (BPS/IC). Values show means and inter-quartile ranges (IQRs)

|                     | Control (N=8) | BPS/IC (N=13) | P-value |
|---------------------|--------------|---------------|---------|
| Uroplakin III IOD   | 1579.5(1505-1645) | 573(509-605.5) | <0.001  |
| TSG-6 IOD           | 1117.5(1016.3-1244.8) | 5466(5337-5580) | <0.001  |

Results

Comparison of human subjects with and without BPS/IC

Figure 1 shows representative immunohistochemical staining images for uroplakin III and TSG-6 in bladder biopsies of control subjects (top) and patients with BPS/IC (bottom). Uroplakin III is expressed on the bladder epithelial cells of control subjects, where it contributes to the protective layer. However, uroplakin III expression is discontinuous in the bladder epithelial cells of patients with IC, suggesting disruption of this protective layer. Similarly, TSG-6 is only expressed on the bladder epithelial cells of control subjects, suggesting that it contributes to the protective layer. However, TSG-6 is expressed in all layers of the bladder in IC subjects, indicative of severe bladder inflammation. These results imply that TSG-6 and uroplakin III are important components of normal bladder epithelial cells, but patients with BPS/IC exhibit disrupted uroplakin III and TSG-6 expression in all layers of the bladder. Table 1 shows a quantitative analysis of these results, based on 8 control patients and 13 BPS/IC patients.

Establishment of a rat model of BPS/IC

We initially validated the rat model of BPS/IC by random allocation of rats into 4 groups (6 rats per group): Control 1W, Control 4W, HAase 1W, and HAase 4W (Table 2). The median urination frequency, inflammation score, number of inflammatory cells, TSG-6 mRNA, IL-6 mRNA, IL-6 protein, and TSG-6 IOD were significantly higher in HAase 1W group than the control 1W group (P<0.002 for all comparisons). In contrast, the median daily urine volume and uroplakin III levels were significantly lower in the HAase 1W group than the control 1W group (P=0.002 for both comparisons). Rats in the control 1W and HAase 1W groups had similar body weight (Table 2).

The median urination frequency, inflammation score, TSG-6 mRNA, IL-6 mRNA, IL-6 protein, and TSG-6 IOD were significantly higher in the HAase 4W group than in the control 4W group (P<0.002 for all comparisons). The median daily urine volume and uroplakin III IOD were significantly lower in the HAase 4W group than in the control 4W group (P=0.002 for both comparisons). Rats in the control 4W and HAase 4W groups had similar body weight (Table 2).
These data validated our rat model of BPS/IC, and indicated that signs and symptoms of BPS/IC are evident after 1 week, and that rats in the HAase 4W group had more severe disease than those in the HAase 1W group.

**TSG-6ameliorates HAase-induced BPS/IC symptoms**

We also examined the effect of TSG-6 administration in our rat model of BPS/IC by comparison of the control 1W, HAase 1W/TSG-6, and HAase 1W/PBS groups (Table 3). The median inflammation score, TSG-6 mRNA, and TSG-6IOD were significantly greater in the HAase 1W/TSG-6 than in the control 1W group.

The median urination frequency, inflammation score, number of inflammatory cells, IL-6 mRNA, and IL-6 protein were significantly greater in the HAase 1W/PBS group than in the control 1W group. On the other hand, the median daily urine volume and uroplakin III level were significantly lower in the HAase 1W/PBS group than in the control 1W group.

**Effect of HAase and TSG-6 on bladder histology**

*Figure 2* shows representative H&E staining images of the bladders of rats in the control 1W, HAase 1W, HAase 1W/TSG-6, and HAase 1W/PBS groups. In agreement with the results above, the bladders of the HAase 1W and HAase 1W/PBS groups had definite signs of pathology, but the bladders of the control 1W and HAase 1W/TSG-6 groups had more normal histology. However, there is no focal deficit in the epithelium of the control 1W and HAase 1W/PBS groups, and there is only moderate cell infiltration in the submucosa in the HAase 1W/PBS group, reflecting an early stage of disease in these rats.

*Figure 3* shows representative immunohistochemical images of uroplakin III (red) and TSG-6 (green) in the bladders of rats in the same 4 groups. In the control 1W rats (top row), TSG-6 and uroplakin III were mainly expressed in the GAG layer of the bladder epithelium, and these proteins form a barrier that protects the bladder epithelium; however, we observed no TSG-6 expression in the lamina propria or tunica muscularis. In the HAase 1W rats (second row), uroplakin III expression was much weaker and

* P<0.05, significantly different with control 1W
† P<0.05, significantly different with HAase 1W/TSG-6. TSG-6: tumor necrosis factor-inducible gene 6, HAase: hyaluronidase, PBS: phosphate-buffered saline
TSG-6 was strongly expressed in the bladder epithelium, submucosal layer, and muscularis layer, but not on the surface of the bladder epithelium. In the HAase 1W/TSG-6 rats (third row), there was high expression of uroplakin III on the surface of the bladder epithelium and high expression of TSG-6 in the full-thickness of the bladder wall. In the HAase 1W/PBS rats (bottom row), expression of uroplakin III and TSG-6 were similar to that observed in the HAase 1W rats.

Discussion

Our results showed expression of TSG-6 on the GAG layer of the bladder epithelium of healthy rats and control human subjects, consistent with the view that this protein has a role in maintaining the integrity of the bladder epithelium in patients and rats with BPS/IC, TSG-6 expression was elevated and was also present in the bladder epithelium, submucosa, and tunica muscularis. However, TSG-6 expression was reduced on the surface of the bladder epithelium. This overall increase of TSG-6 expression may be a protective response to BPS/IC. In agreement with this interpretation, we also found that TSG-6 administration had an anti-inflammatory effect in the bladders of rats with BPS/IC, in addition, prevented damage of the bladder epithelial barrier, and normalized urinary metabolism.

Two recent review articles of TSG-6 (19, 20) reported abundant evidence for upregulation of this protein following inflammation, but no previous studies reported expression of TSG-6 in healthy bladder tissues. Thus, a novel finding of our study is that TSG-6 expression occurred on the surface of the bladder epithelium of healthy rats and of control human subjects. Based on our experience, improper preparation of tissue samples may damage the GAG layer of the bladder epithelium, and this could result in non-detection of TSG-6. This may explain, in part, the reasons for the variable results of previous studies (16, 27, 31). In the healthy rat bladder, TSG-6 and uroplakin III had similar cellular distributions on the surface of bladder epithelium, although we did not assess their precise subcellular distributions. The GAG layer is an important physical barrier (32, 33). Thus, we speculate that toxic substances in the urine stimulate the production of TSG-6, which interacts with components of the GAG (HA, heparin, and chondroitin sulfate), and this helps to restore the bladder function. In control human subjects, TSG-6 is also found in the GAG layer of the bladder epithelium, in contrast to the expression pattern in rats. Nonetheless, TSG-6 also has a role in maintenance of the bladder epithelial barrier in humans.

The important role of TSG-6 in maintaining the bladder epithelium led to our hypothesis that administration of TSG-6 might reverse the damage from BPS/IC. Previous studies indicated that TSG-6 can cross-link with the components of the ECM (including HA, heparin, and chondroitin sulfate) to stabilize the GAG layer, and is a potential regulator of HA synthesis (21). Recent clinical studies have used bladder perfusion with exogenous HA to repair the GAG layers of patients with BPS/IC (3, 10). The present study showed that the bladders of rats with BPS/IC had disrupted uroplakin III expression, and that TSG-6 therapy normalized expression of this protein, repaired the structure of bladder epithelium, and restored bladder function.

TSG-6 expression is increased in diverse acute and chronic inflammatory conditions, and this appears to be a protective response (19, 20). Our clinical results indicated that controls had TSG-6 expression on the bladder epithelia, but not on the submucosa; however, in the presence of BPS/IC, TSG-6 expression was significantly increased in the bladder epithelia, submucosa, and tunica muscularis. TSG-6 expression was also elevated in rats with BPS/IC. These observations are consistent with the observation that TSG-6 expression is elevated in osteoarthritis (22), and suggest that TSG-6 may be useful as a marker of inflammation in BPS/IC. Although TSG-6 is expressed in the bladder epithelia, submucosa, and tunica muscularis of rats with BPS/IC, expression was lower on the surface of the bladder epithelium. These results are consistent with our clinical findings. The low expression of TSG-6 in the bladder epithelia of BPS/IC rats may be due to HAase-induced degradation of the GAG layer, and the subsequent disruption of the bladder barrier. This also supports the view that TSG-6 is important in maintenance of the GAG layer.

Previous studies have confirmed the therapeutic efficacy of TSG-6 in several models of inflammatory diseases. For example, in rats with corneal injury, injection of the aqueous chamber with TSG-6 improved corneal transparency and reduced angiogenesis (27). In mice with lipopolysaccharide-induced lung injury, administration of TSG-6 attenuated lung injury (34). In mice with myocardial infarction, intravenous injection of TSG-6 reduced the infarct area and improved cardiac function (16). Previous studies of BPS/IC indicated the presence of hyperplastic mast cells (31), and that TSG-6 may exert anti-inflammatory effects by inhibiting the tryptase activity of these cells (35). In the present study, rats with BPS/IC had bladder inflammation, altered urination patterns, and related symptoms, and TSG-6 therapy led to significant resolution of these histological and metabolic changes. Our previous study (2) showed that IL-6 expression in the bladder of rats with HAase-induced cystitis correlated with disease severity, suggesting that IL-6 may be a useful marker for chronic cystitis (2). In the present study, similar to that reported in other inflammatory disease models (27), bladder expression of IL-6 declined significantly after TSG-6 therapy, confirming the anti-inflammation role of TSG-6.
inflammatory effects of this protein. A limitation of this study is that we do not have data for mice given 4 weeks of HAase + TSG, so cannot assess the effect of TSG-6 in mice with more advanced disease. Another limitation is that the control group of human subjects consisted of only 8 patients in whom there was no diagnosis of BPS/IC.

Conclusion

Our results indicate that TSG-6 plays an important role in the integrity of the bladder epithelial barrier. BPS/IC leads to disruption of this barrier, and increased TSG-6 expression throughout the bladder is a protective response. This increased TSG-6 expression appears to have anti-inflammatory effects, so this protein may be a useful marker of inflammation in BPS/IC. TSG-6 administration ameliorated the HAase-induced cystitis and urination behavior in rats, and repaired the bladder barrier. These results suggest the potential of using TSG-6 for therapy of BPS/IC.

Acknowledgment

This study was supported by the Foundation for Young Scientists of the Education Bureau of Fujian Province, China (Grant No.:JA14148).

Conflict of interest

The authors declare that there are no conflicts of interest.
