ABSTRACT

We present results of a simulation of two flavor QCD on a $16^3 \times 4$ lattice using p4-improved staggered fermions with bare quark mass $m/T = 0.4$. Derivatives of the thermodynamic grand canonical partition function $Z(V, T, \mu_u, \mu_d)$ with respect to chemical potentials $\mu_{u,d}$ for different quark flavors are calculated up to sixth order, enabling estimates of the pressure and the quark number density as well as the chiral condensate and various susceptibilities as functions of $\mu_q = (\mu_u + \mu_d)/2$ via Taylor series expansion. Furthermore, we analyze baryon as well as isospin fluctuations and discuss the relation between the radius of convergence of the Taylor series and the chiral critical point in the QCD phase diagram. We argue that bulk thermodynamic observables do not, at present, provide direct evidence for the existence of a chiral critical point in the QCD phase diagram. Results are compared to high temperature perturbation theory as well as a hadron resonance gas model.

1 Introduction

The thermodynamics of strongly interacting matter has been studied extensively in lattice calculations at vanishing quark chemical potential, $\mu_q$ (or baryon $\mu_B \equiv 3\mu_q$) [1]. Current lattice calculations strongly suggest that the transition from the hadronic low temperature phase to the high temperature phase is a continuous, non-singular but rapid transition happening in a narrow temperature interval around the transition temperature $T_0 \approx 170$ MeV. Recent advances in the development of techniques for lattice calculations at non-zero quark chemical potential $\mu_q$ [2–6] have also enabled the first exploratory studies of the QCD phase diagram and bulk thermodynamics in a regime of small $\mu_q$, i.e. for $\mu_q/T \lesssim 1$ and $T \geq 0.8 T_0$.

Guided by phenomenological models which suggest that at low temperature and non-zero quark chemical potential the low and high density regions will be separated by a first order phase transition it has been speculated [7] that a 2$^{nd}$ order phase transition point, the chiral critical point, exists in the interior of the QCD phase diagram, at which the line of first order transitions ends. For smaller values of $\mu_q/T$ the low and high temperature regime will then be only separated by a crossover transition. The first exploratory studies at non-zero quark chemical potential indeed gave evidence for such a chiral critical point [2], although subsequent investigations made clear that at present any quantitative statement about the location [8,9] and maybe even about the existence of such a chiral critical point is premature. The first calculations of the baryonic contribution to the pressure in strongly interacting matter [3,10–14] also suggested that the transition and the thermodynamic behaviour in the high-T phase resemble the picture found previously at zero net baryon density. In this case ($\mu_q = 0$) the transition occurs over a narrow temperature interval. Beyond a region $T \in [T_0, 1.5T_0]$ where there are large deviations from ideal gas behaviour, thermodynamic observables rapidly approach the high-T ideal gas limit; for instance, the pressure agrees with the Stefan-Boltzmann prediction to within $\sim 20\%$. In the low temperature hadronic phase it has been found that a hadron resonance gas model provides an astonishingly good description of basic features of the $T$ and $\mu_q$-dependence of thermodynamic observables [15].

Maybe one of the largest changes compared to the thermodynamics at $\mu_q \equiv 0$ has been observed in the temperature dependence of the quark number and isovector susceptibilities [11]. For $\mu_q = 0$ these observables show a similar temperature dependence. They have been found to change rapidly at the transition temperature but continue to increase monotonically at larger temperatures [16–20]. For $\mu_q > 0$, however, the quark number susceptibility develops a pronounced peak at the transition temperature while the isovector susceptibility continues to show a temperature dependence similar to that
found at $\mu_q = 0$. Such a behavior, indeed, is expected to occur in QCD in the vicinity of a $2^{nd}$ order phase transition point [21]. Susceptibilities thus may provide the most direct evidence for the existence of a $2^{nd}$ order phase transition in the QCD phase diagram. Finding the characteristic volume and/or quark mass dependent universal scaling behavior$^a$ of susceptibilities would undoubtedly establish the existence of a chiral critical point.

In this paper we want to extend our previous study of thermodynamics at non-zero quark chemical potential [3,11], which is based on a Taylor series expansion around $\mu_q = 0$, to the $6^{th}$ order$^b$. Going to higher orders in the expansion is of particular importance for the analysis of higher derivatives of the density of the grand potential expressed in units of the temperature$^c$, $\Omega(V,T,\mu) \equiv (VT^3)^{-1} \ln Z$, i.e. for an analysis of generalized susceptibilities. Accordingly our main emphasis will be to further analyze the properties of quark number and isovector susceptibilities, relate them to diagonal and non-diagonal flavor susceptibilities, calculate the chiral susceptibility and discuss to what extent the pronounced peaks found in some of these susceptibilities give evidence for the existence of a chiral critical point in the QCD phase diagram.

This paper is organized as follows. We start in the next section by summarizing basic results on QCD thermodynamics at non-zero quark chemical potential obtained in high temperature perturbation theory [22, 23] and expectations based on properties of the hadron resonance gas model at low temperature [24, 25]. In section 3 we present results on the calculation of various thermodynamic observables obtained from a Taylor expansion up to $6^{th}$ order in $\mu_q/T$. In section 4 we analyze the convergence properties of the Taylor series. Section 5 is devoted to a discussion of the reweighting approach to QCD thermodynamics at $\mu_q \neq 0$ and its comparison to the Taylor expansion approach. In section 6 we give our conclusions. An Appendix contains details on the Taylor expansion of various observables studied here.

## 2 Thermodynamics at low and high temperature

In this section we want to briefly discuss the density or chemical potential dependence of thermodynamic observables in the asymptotic high temperature regime as well as at low temperatures in the hadronic phase of QCD. On the former we have information from high temperature perturbation theory which recently has been extended to $O(g^6 \ln g)$ [23] also for non-vanishing quark chemical potentials $\mu_f, f = u, d, ..$, and as for $\mu_f \equiv 0$ [26]

$^a$The $2^{nd}$ order critical point in the QCD phase diagram is expected to belong to the universality class of the 3-dimensional Ising model.

$^b$Some results on the radius of convergence have been reported recently in an $8^{th}$ order Taylor expansion for two flavor QCD [20].

$^c$We will call this in the following the grand potential although conventionally the extensive quantity $VT^3\Omega$ is called the grand potential.
is thus now known to all perturbatively calculable orders. Although a comparison of the perturbative expansion with lattice calculations at $\mu_f = 0$ suggests that quantitative agreement cannot be expected at temperatures close to the transition temperature, $T_0$, we can gain useful insight into the structure of the Taylor expansion used in lattice calculations to study thermodynamics at $\mu_f \neq 0$.

In the low temperature hadronic phase a systematic QCD based analysis is difficult and one generally has to rely on calculations within the framework of effective low energy theories or to phenomenological approaches. Here we will focus on a discussion of the properties of a hadron resonance gas model, which recently has been compared to lattice results at non-zero quark chemical potential quite successfully [15] and which also is known to describe experimental results on the chemical freeze-out of particle ratios observed in heavy ion collisions rather well [25].

2.1 High temperature perturbation theory

In the infinite temperature limit the grand potential of QCD\textsuperscript{d}, $\Omega(T, \mu) \equiv \ln Z(V, T, \mu)/VT^3$, which is equivalent to the pressure in units of $T^4$, approaches that of a free quark-gluon gas (Stefan-Boltzmann (SB) gas),

\begin{equation}
\frac{p_{SB}}{T^4} = \frac{8\pi^2}{45} + \sum_{f=u,d,\ldots} \left[ \frac{7\pi^2}{60} + \frac{1}{2} \left( \frac{\mu_f}{T} \right)^2 + \frac{1}{4\pi^2} \left( \frac{\mu_f}{T} \right)^4 \right], \tag{2.1}
\end{equation}

where the first term gives the contribution of the gluon sector and the sum over the fermion sector extends over $n_f$ different flavors. In Eq. (2.1) we only gave the result for massless quarks and gluons. Also in the following we will restrict our discussion of perturbative results to the case of QCD with massless quarks. In this section we also use $\mu$ to denote the entire set of $n_f$ different chemical potentials ($\mu_u$, $\mu_d$, ...). We also introduce the shorthand notation $\mu^2 = \sum_f (\mu_f/T)^2$.

The additive structure of contributions arising from gluons and the different fermion flavor sectors persists at $O(g^2)$. Only starting at $O(g^3)$ is a coupling among the different partonic sectors introduced. At this order it is induced through the non-vanishing electric (Debye) mass term $m_E$ [23],

\begin{equation}
\Omega(T, \mu) = \Omega^{(0)}(T, \mu) + g^2 \Omega^{(2)}(T, \mu) + g^3 \Omega^{(3)}(T, \mu) + O(g^4), \tag{2.2}
\end{equation}

\textsuperscript{d}We suppress here the volume dependence of $\Omega$. Perturbative calculations are performed in the thermodynamic limit. The volume dependence, however, has to be analyzed more carefully in lattice calculations.
with
\[
\begin{align*}
\Omega^{(2)}(T, \mu) &= - \left( \frac{1}{6} + \frac{5n_f}{72} + \frac{1}{4\pi^2}\mu^2 + \frac{1}{8\pi^4} \sum_{f=u,d,\ldots} \left( \frac{\mu_f}{T} \right)^4 \right), \\
\Omega^{(3)}(T, \mu) &= \frac{1}{6\pi} \left( \frac{m_E}{gT} \right)^3 = \frac{1}{6\pi} \left( 1 + \frac{n_f}{6} + \frac{1}{2\pi^2}\mu^2 \right)^{3/2}.
\end{align*}
\] (2.3)

The electric mass term introduces a dependence of a given quark flavor sector on changes in another sector, i.e. the quark number density in a flavor sector \( \ell \),
\[
\frac{n_\ell}{T^3} = \frac{\partial \Omega(T, \mu)}{\partial \mu_\ell/T},
\] (2.4)
depends on the other quark chemical potentials only at \( \mathcal{O}(g^3) \). This is also reflected in the structure of diagonal and non-diagonal susceptibilities [4,16–20].

\[
\frac{\chi_{ff}(T, \mu)}{T^2} = \frac{\partial^2 \Omega(T, \mu)}{\partial (\mu_f/T)^2}, \quad \frac{\chi_{fk}(T, \mu)}{T^2} = \frac{\partial^2 \Omega(T, \mu)}{\partial (\mu_f/T) \partial (\mu_k/T)}.
\] (2.5)

The diagonal susceptibilities are non-zero in the ideal gas limit and, moreover, the leading order perturbative term stays non-zero also in the limit of vanishing quark chemical potential,
\[
\frac{\chi_{ff}(T, \mu)}{T^2} = 1 + \frac{3}{\pi^2} \left( \frac{\mu_f}{T} \right)^2 + \mathcal{O}(g^2).
\] (2.6)

The non-diagonal susceptibilities, however, receive non-zero contributions only at \( \mathcal{O}(g^3) \). The leading perturbative contribution is positive and inversely proportional to the electric screening mass. However, it vanishes in the limit of vanishing chemical potentials. In this case the first non-zero contribution arises at \( \mathcal{O}(g^6 \ln 1/g) \) [22],
\[
\frac{\chi_{fk}(T, \mu)}{T^2} = \frac{g^3}{2\pi^5} \left( 1 + \frac{n_f}{6} + \frac{1}{2\pi^2}\mu^2 \right)^{-1/2} \frac{\mu_f \mu_k}{T^3} + \mathcal{O}(g^4),
\] (2.7)
\[
\frac{\chi_{fk}(T, 0)}{T^2} \approx - \frac{5}{144\pi^6} g^6 \ln 1/g.
\] (2.8)

As we are going to discuss lattice calculations at non-zero chemical potential which are based on a Taylor expansion of the grand potential \( \Omega \) in terms of \( \mu_f/T \) it also is instructive to consider a Taylor expansion of the perturbative series for \( \Omega \). While perturbative terms
up to $O(g^2)$ only contribute to the series up to $O(\mu^4)$ higher order terms in the expansion start receiving non-vanishing contributions at $O(g^3)$. These again arise from the electric mass term, i.e. from an expansion of $m_E/gT$ in powers of $\mu^2$.

$$\Omega^{(3)} = \frac{1}{6\pi} \left(1 + \frac{n_f}{6}\right)^{3/2} + \frac{1}{8\pi^3} \left(1 + \frac{n_f}{6}\right)^{1/2} \mu^2 + \frac{1}{64\pi^5} \left(1 + \frac{n_f}{6}\right)^{-1/2} (\mu^2)^2 - \frac{1}{768\pi^7} \left(1 + \frac{n_f}{6}\right)^{-3/2} (\mu^2)^3 + O(\mu^8).$$ (2.9)

Note that the expansion coefficients up to and including $O(\mu^4)$ are positive. Starting at $O(\mu^6)$ they alternate in sign. From the sign of the $\mu^6$-term it follows via Eq. (2.5) that the leading perturbative contribution to the expansion coefficient of diagonal as well as non-diagonal susceptibilities at $O(\mu^4)$ is negative, with the latter being an order of magnitude smaller.

Rather than discussing the thermodynamics of QCD at non-vanishing quark chemical potential in terms of chemical potentials related to quark numbers in different flavor channels, it is convenient to introduce chemical potentials which are related to conserved quantum numbers considered at low energy, i.e. quark or baryon number and isospin. In the case of two flavor QCD, which we are going to analyze in our lattice calculations, we thus introduce also the quark chemical potential, $\mu_q = (\mu_u + \mu_d)/2$ and the isovector chemical potential $\mu_I = (\mu_u - \mu_d)/2$. In analogy to Eq. (2.5) we then can introduce quark number and isovector susceptibilities,

$$\frac{\chi_q}{T^2} = \frac{\partial^2 \Omega}{\partial (\mu_q/T)^2} \equiv 2 (\chi_{uu} + \chi_{ud}), \quad \frac{\chi_I}{T^2} = \frac{\partial^2 \Omega}{\partial (\mu_I/T)^2} \equiv 2 (\chi_{uu} - \chi_{ud}),$$ (2.10)

where in the second equality we have assumed degenerate $(u, d)$-quark masses.

### 2.2 Low temperature hadron resonance gas

The success in describing particle abundance ratios observed in heavy ion experiments at varying beam energies in terms of equilibrium properties of a hadron resonance gas model [25] begs a comparison of this model for the low temperature hadronic phase with lattice QCD calculations. Indeed this led to astonishingly good agreement [15].

In the hadron resonance gas (HRG) model it is assumed that for $T < T_0$ the QCD partition function can be approximated by that of a non-interacting gas of hadron resonances, either bosonic mesons or fermionic baryons. This, however, does not mean that

---

6. It has also recently been pointed out in the context of a large-$N_c$ expansion that flavor non-diagonal contributions to the free energy are suppressed by $O(1/N_c^2)$ [27].

7. This definition of the isovector chemical potential differs from that used in [11] by a factor of 2.
interactions in dense hadronic matter have been ignored; in the spirit of Hagedorn’s bootstrap model [24] the inclusion of heavy resonances as stable particles also takes care of the interaction among the hadrons in the dense gas at low temperature.

The partition function of the hadron resonance gas may be split into mesonic and baryonic contributions,

\[
\ln Z_{HRG}(T, V, \mu_q, \mu_I) = \sum_{i \in \text{mesons}} \ln Z_{m_i}^M(T, V, \mu_q, \mu_I) + \sum_{i \in \text{baryons}} \ln Z_{m_i}^B(T, V, \mu_q, \mu_I), \tag{2.11}
\]

where

\[
\ln Z_{m_i}^{M/B}(T, V \mu_q, \mu_I) = \mp \frac{V}{2\pi^2} \int_0^\infty dk k^2 \ln(1 \mp z_i e^{-\varepsilon_i/T}), \tag{2.12}
\]

with energies \(\varepsilon_i^2 = k^2 + m_i^2\) and fugacities

\[
z_i = \exp \left(\frac{3B_i \mu_q + 2I_3 \mu_I}{T}\right). \tag{2.13}
\]

Here \(B_i\) is the baryon number and \(I_3\) denotes the third component of the isospin of the species in question. The upper sign in Eq. (2.12) refers to bosons, and the lower sign to fermions. Note that with this convention anti-particles must be counted separately in Eq. (2.11) with fugacity \(z_i^{-1}\), and self-conjugate species such as \(\pi^0, \eta'\) have \(z = 1\). If the logarithms are expanded in powers of fugacity, the integral over momenta, \(k\), can be performed. This yields

\[
\ln Z_{m_i}^{M/B} = \frac{V T m_i^2}{2\pi^2} \sum_{\ell=1}^\infty \left\{ \frac{1}{(-1)^{\ell+1}} \right\} \ell^{-2} K_2 \left(\frac{\ell m_i}{T}\right) z_i^\ell, \tag{2.14}
\]

where the upper factor in braces applies to bosons and the lower to fermions, and \(K_2\) is a modified Bessel function. For large argument, i.e. for \(m_i \gg T\) the Bessel function can be approximated by \(K_2(x) \sim \sqrt{\pi/2x} e^{-x}(1 + 15/8x + \mathcal{O}(x^{-2}))\). Terms with \(\ell \geq 2\) in the series given in Eq. (2.14) thus are exponentially suppressed. For temperatures and quark chemical potentials less than a typical scale of about 200 MeV it generally suffices to keep the first term in the sum appearing in Eq. (2.14). The only species for which this step would need further justification is the pion; clearly for realistic pion masses more care must be taken when evaluating the sum over \(\ell\). This, however, does not influence the \(\mu_q\)-dependence of the hadron resonance gas; \(B_i = 0\) for mesons and their contribution thus is independent of \(\mu_q\). At \(\mu_I = 0\) one readily derives,

\[
\frac{p(T, \mu_q)}{T^4} = \frac{1}{VT^3} \ln Z_{HRG}\bigg|_{\mu_I=0} \simeq G(T) + F(T) \cosh \left(\frac{3\mu_q}{T}\right), \tag{2.15}
\]
with \( G(T) = (VT^3)^{-1} \sum_{i \in \text{mesons}} \ln Z_{m_i}^M \) and \( F(T) \) given by the Boltzmann approximation to the fermion partition function of baryons,

\[
F(T) = \frac{1}{\pi^2} \sum_{i \in \text{baryons}} \left( \frac{m_i}{T} \right)^2 K_2 \left( \frac{m_i}{T} \right) .
\]  

(2.16)

Note that each term in the sum for \( F \) now counts both baryon and anti-baryon. As the meson sector of the partition functions is independent of \( \mu_q \), the mesonic component does not contribute to \( \chi_q \),

\[
\frac{\chi_q}{T^2} = 9 F(T) \cosh \frac{3\mu_q}{T} .
\]  

(2.17)

Similarly, at \( \mu_I = 0 \) we find for the isovector susceptibility

\[
\frac{\chi_I}{T^2} = G^I(T) + F^I(T) \cosh \frac{3\mu_q}{T}
\]  

with

\[
G^I(T) = \frac{1}{2\pi^2} \sum_{i \in \text{mesons}} \sum_{\ell=1}^\infty (2I_3)^2 \left( \frac{m_i}{T} \right)^2 K_2 \left( \frac{\ell m_i}{T} \right) ,
\]

\[
F^I(T) = \frac{1}{\pi^2} \sum_{i \in \text{baryons}} (2I_3)^2 \left( \frac{m_i}{T} \right)^2 K_2 \left( \frac{m_i}{T} \right) .
\]  

(2.19)

where again only in the baryon sector \( \ell > 1 \) terms have been neglected.

The resonance gas model in the (partial) Boltzmann approximation given by Eqs. (2.15)-(2.19) leads to simple predictions for the dependence of thermodynamic observables on the quark chemical potential \( \mu_q \). In particular, it predicts that ratios of the density dependent part of thermodynamic observables are insensitive to details of the hadronic mass spectrum. Nor do they depend explicitly on temperature, but instead only on the ratio \( \mu_q/T \). For instance, one finds

\[
\frac{p(T, \mu_q) - p(T, 0)}{\chi_q T^2} = \cosh(3\mu_q/T) - 1 \ , \quad \frac{n_q}{\mu_q \chi_q} = \frac{T}{3\mu_q} \tanh \left( \frac{3\mu_q}{T} \right) .
\]  

(2.20)

Similarly ratios of Taylor expansion coefficients of thermodynamic quantities, \( X \), are temperature and spectrum independent. For an observable \( X \), of generic form \( X = G^X + F^X \cosh(3\mu_q/T) \), the expansion in \( \mu_q/T \) is given by

\[
X = \sum_{n=0}^\infty c_n^X (\mu_q/T)^n .
\]  

(2.21)
with
\[ c_0^X = G^X + F^X, \quad c_{2n}^X = \frac{9^n}{(2n)!} \frac{F^X}{(2n)!} \] (2.22)

and \( c_{2n+1}^X = 0 \). Hence, ratios are given by
\[ \frac{c_{2n+2}^X}{c_{2n}^X} = \frac{9}{(2n + 2)(2n + 1)} \quad \text{for } n \geq 1. \] (2.23)

These ratios as well as ratios of physical observables calculated within the resonance gas approximation will be compared to corresponding lattice results in the following.

3 Taylor expansion for two flavor QCD

The basic concepts of our Taylor expansion approach to QCD thermodynamics at non-zero quark chemical potential have been introduced in [11] where observables have been analyzed up to \( O(\mu_q^4) \). Here we extend the analysis up to the sixth order in \( \mu_q/T \) with significantly improved statistics.

Our calculations have been performed for two flavor QCD on an \( 16^3 \times 4 \) lattice with bare quark mass \( m_a = 0.1 \) using Symanzik-improved gauge and p4-improved staggered fermion actions. These parameters are identical to those used for our analysis of thermodynamic observables at non-zero chemical potential up to \( O(\mu_q^4) \) [3, 11]. The simulation uses the hybrid R molecular dynamics algorithm, and measurements were performed on equilibrated configurations separated by 5 units of molecular dynamics time \( \tau \). The gauge couplings, \( \beta = 6/g^2 \), used for our calculations cover the interval [3.52,4.0], which corresponds to a temperature range \( T/T_0 \in [0.76,1.98] \), where \( T_0 \) is the pseudocritical temperature at \( \mu = 0 \) for which we use\(^6 \beta_c = 3.65 \). This value is used to define the temperature scale \( T/T_0 \). The number of configurations generated at each \( \beta \)-value is given in Table 3.1. The third and seventh columns give the sample sizes used in [11], where coefficients up to \( n = 4 \) were calculated. The numbers of additional configurations generated for the present study of expansion coefficients up to \( n = 6 \) are listed in the fourth and eighth columns. It can be seen that we have increased our statistics in the hadronic phase by a factor 4-5 and in the plasma phase by a factor 3.

For the calculation of various operator traces we use the method of noisy estimators. We generally found that expectation values involving odd derivatives of \( \ln \det M \) with

---

\(^6\)In [3] we determined as critical coupling \( \beta_c = 3.649(2) \). Our current analysis favors a slightly larger value, \( \beta_c = 3.655(5) \).
Table 3.1: Sample size at each $\beta$ value.

| $\beta$ | $T/T_c$ | #(2,4) | #(2,4,6) | $\beta$ | $T/T_c$ | #(2,4) | #(2,4,6) |
|---------|---------|--------|---------|---------|---------|--------|---------|
| 3.52    | 0.76    | 1000   | 3500    | 3.70    | 1.11    | 800    | 2000    |
| 3.55    | 0.81    | 1000   | 3500    | 3.72    | 1.16    | 500    | 2000    |
| 3.58    | 0.87    | 1000   | 3500    | 3.75    | 1.23    | 500    | 1000    |
| 3.60    | 0.90    | 1000   | 3800    | 3.80    | 1.36    | 500    | 1000    |
| 3.63    | 0.96    | 1000   | 3500    | 3.85    | 1.50    | 500    | 1000    |
| 3.65    | 1.00    | 1000   | 4000    | 3.90    | 1.65    | 500    | 1000    |
| 3.66    | 1.02    | 1000   | 4000    | 3.95    | 1.81    | 500    | 1000    |
| 3.68    | 1.07    | 800    | 3600    | 4.00    | 1.98    | 500    | 1000    |

respect to $\mu$ are noisier and require averages over more random vectors than needed to estimate expectation values involving only even derivatives. Odd derivatives have to appear in even numbers in an expectation value in order for this to be non-zero. Such expectation values behave very much like susceptibilities and receive their largest contributions in the vicinity of $T_0$. Still their total contribution to the expansion of e.g. the pressure is found to be small up to $O(\mu^4)$. It only becomes sizeable at $O(\mu^6)$. For these reasons we used 100 stochastic noise vectors to estimate operator traces on each configuration for $\beta \in [3.60, 3.68]$. For other $\beta$ values 50 noise vectors were found to suffice.

### 3.1 Pressure, quark number density and susceptibilities

To start the discussion of lattice results on thermodynamics of two flavor QCD for small values of the quark chemical potential we will present results obtained from a Taylor expansion of the grand potential $\Omega(T, \mu_u, \mu_d) \equiv \Omega(T, \mu_q + \mu_I, \mu_q - \mu_I)$ and some of its derivatives. We will consider expansions in terms of $\mu_q/T$ at fixed, vanishing $\mu_I$. The pressure is then given by

$$
\frac{p}{T^4} \equiv \Omega(T, \mu_q, \mu_q) = \sum_{n=0}^{\infty} c_n(T) \left( \frac{\mu_q}{T} \right)^n.
$$

(3.1)

CP symmetry implies that the series is even in $\mu_q$, so the coefficients $c_n$ are non-zero only for $n$ even, and are defined as

$$
c_n(T) = \frac{1}{n!} \left. \frac{\partial^n \Omega}{(\mu_q/T)^n} \right|_{\mu_q=0} = \frac{1}{n!} \frac{N_3^2}{N_3} \left. \frac{\partial^n \ln Z}{(\mu N_T)^n} \right|_{\mu=0},
$$

(3.2)
| $T/T_c$ | $c_2$ | $c_4 \times 10$ | $c_6 \times 10^2$ | $c_2'$ | $c_4' \times 10$ | $c_6' \times 10^2$ |
|--------|-------|----------------|-----------------|--------|----------------|-----------------|
| 0.76   | 0.0243(19) | 0.238(61) | -1.12(121) | 0.0649(6) | 0.098(5) | 0.23(9) |

Table 3.2: Taylor expansion coefficients $c_n(T)$ and $c'_n(T)$.

where in the second equality we have explicitly specified that the calculations have been performed on a $N^3_σ \times N_τ$ lattice with dimensionless quark chemical potential $μ ≡ μ_q a$. $Z$ denotes the lattice regularized partition function for two flavor QCD. Similarly we calculate the quark number density

$$\frac{n_q(T, μ_q)}{T^3} = \frac{∂Ω(T, μ_q, μ_q)}{μ_q/T} = 2c_2 \left( \frac{μ_q}{T} \right) + 4c_4 \left( \frac{μ_q}{T} \right)^3 + 6c_6 \left( \frac{μ_q}{T} \right)^5 + \cdots , \quad (3.3)$$

as well as the quark and isovector susceptibilities using Eq. (2.10),

$$\frac{\chi_q(T, μ_q)}{T^2} = 2c_2 + 12c_4 \left( \frac{μ_q}{T} \right)^2 + 30c_6 \left( \frac{μ_q}{T} \right)^4 + \cdots \quad (3.4)$$

$$\frac{\chi_I(T, μ_q)}{T^2} = 2c_2' + 12c_4' \left( \frac{μ_q}{T} \right)^2 + 30c_6' \left( \frac{μ_q}{T} \right)^4 + \cdots \quad (3.5)$$

where

$$c_n' = \frac{1}{n!} \frac{∂^n}{∂(μ_l/T)^2}(μ_q/μ_I - μ_I) \bigg|_{μ_q=0, μ_l=0} \quad (3.6)$$
Figure 3.1: The Taylor expansion coefficients $c_n$ and $c_n^I$ for $n = 2, 4$ and 6 as functions of $T/T_0$.

Explicit expressions for $c_2$, $c_4$, $c_6$ and $c_2^I$, $c_4^I$ and $c_6^I$ are given in the Appendix. Note that the expansion for the quark number susceptibility $\chi_q$ given in Eq. (3.4) is a derivative of the grand potential at $\mu_I \equiv 0$ and thus has the same radius of convergence as that of the pressure and quark number density given by Eqs. (3.1) and (3.3). The expansion coefficient $c_2^I$ also defines the first term in an expansion of the pressure at non-zero isospin. This series may have a different radius of convergence [28]; indeed, since the lightest particle carrying non-zero isospin $I_3$ in the hadronic phase is the pion, we might expect the expansion to break down in the chiral limit for arbitrarily small $\mu_I$.

The coefficient $c_0(T)$ gives the pressure in units of $T^4$ at vanishing baryon density and can be calculated using the integral method [29]. It is the only expansion coefficient which also requires lattice calculations at zero temperature. Higher order terms can be calculated directly from gauge field configurations generated on finite temperature lattices. They, however, require additional derivatives of $\ln \det M$, where $M$ is the quark matrix. They are evaluated at fixed temperature, i.e. fixed gauge coupling $\beta$, by calculating combinations of traces of products of $\partial^m M/\partial \mu^m$ and $M^{-1}$ (see Appendix).

Results for the Taylor expansion coefficients are listed in Table 3.2. In Fig. (3.1) we plot $c_n$ and $c_n^I$ for $n = 2, 4$ and 6 as functions of $T$. A comparison with Figs. 3 and 8 of Ref. [11] reveals the improvement in statistics of the current study. The same features are apparent: namely $c_2$ and $c_2^I$ both rise steeply across $T_0$ with $c_2^I > c_2$ as is obvious from the explicit expressions given for these coefficients in the appendix; they reach a plateau at approximately 80% of the value $n_\ell/2$ predicted in the Stefan-Boltzmann (SB) limit, i.e. for free massless quarks; $c_4$ rises steeply to peak at $T \simeq T_0$ before approaching its SB limit value $n_\ell/4\pi^2$ from above, whereas the peak in $c_4^I$ is much less marked$^b$.

$^b$The difference is largely due to the dominance of the disconnected term $\langle (\partial^2 \ln \det M/\partial \mu^2)^2 \rangle - \langle \partial^2 \ln \det M/\partial \mu^2 \rangle^2$ which contributes to $c_4$ with a coefficient three times that of its contribution to $c_4^I$. 

As can be seen in Table 3.2 in the high temperature phase the 6th order expansion coefficients generally are an order of magnitude smaller than the 4th order coefficients. In the low temperature phase they are still a factor 3-5 smaller. As a consequence the 6th order contributions to the pressure and quark number density are small for \( \mu_q/T \leq 1 \). This is seen in Fig. (3.2) which shows \( \Delta p/T^4 \equiv (p(T, \mu_q) - p(T, 0))/T^4 \) and \( n_q/T^3 \) in the range \( 0 \leq \mu_q/T \leq 1 \). Here we also show as dashed lines results obtained from a Taylor expansion which includes only terms up to 4th order in \( \mu_q/T \). This suggests that the expansion for the pressure and quark number density is converging rapidly for \( \mu_q/T < 1 \). Even for \( \mu_q/T = 1 \) the differences between the 4th and 6th-order results are small and partly influenced by statistics. We also note that in the high temperature regime, \( T \gtrsim 1.5T_0 \), our results are compatible with the continuum extrapolated (quenched) results obtained with an unimproved staggered fermion action [13]. This supports the expectation that deviations from the continuum limit are strongly suppressed with our improved action.

Next we turn to a discussion of quark number and isovector susceptibilities which are shown in Fig. (3.3). They have been obtained using Eqs. (3.4) and (3.5). Again we show the corresponding 4th-order results as dashed lines in these figures. These lines agree with our old results shown as Fig. 9 of [11]. The effect of the new term proportional to \( c_6(T) \) is to shift the apparent maximum in \( \chi_q(T) \), arising from the sharply peaked \( \mu_q^4 \)-contribution proportional to \( c_4(T) \), to lower temperature. This suggests that the transition
Figure 3.3: The quark number susceptibility $\chi_q/T^2$ (left) and isovector susceptibility $\chi_I/T^2$ (right) as functions of $T/T_0$ for various $\mu_q/T$ ranging from $\mu_q/T = 0$ (lowest curve) rising in steps of 0.2 to $\mu_q/T = 1$, calculated from a Taylor series in $6^{th}$ order. Also shown as dashed lines are results from a $4^{th}$ order expansion in $\mu_q/T$.

temperature at non-zero $\mu_q$ determined from the peak position of susceptibilities indeed moves to temperatures smaller than the transition temperature $T_0$ determined at $\mu_q = 0$. The figure, however, also shows that at least for $T < T_0$ the $6^{th}$-order contribution can be sizeable and still suffers from statistical errors. Better statistics and the contribution from higher orders in the Taylor expansion thus will be needed to get good quantitative results for susceptibilities in the hadronic phase.

There is also a pronounced dip in $\chi_q(T)$ for $T/T_0 \simeq 1.05$ which, together with the increased error bars makes the presence of a peak in $\chi_q$ less convincing then it is without the inclusion of the $\mu_q^6$-contribution. However, the error bars also reflect the problem we have at present in determining this additional contribution with sufficient accuracy to include it in the calculation of higher order derivatives of the partition function. On the other side, Fig. (3.3) confirms that a significant peak is not present in the isovector channel. In fact, if a critical endpoint exists in the $(T, \mu)$-plane of the QCD phase diagram, this is expected to belong to the Ising universality class, implying that exactly one $3d$ scalar degree of freedom becomes massless at this point. Since both $\bar{\psi}\psi$ and $\bar{\psi}\gamma_0\psi$ are isoscalar and Galilean scalars, both are candidates to interpolate this massless field, and hence we can expect divergent fluctuations in both quark number and chiral susceptibilities at this point. The latter will be discussed in section 3.3.

The difference in the temperature dependence of $\chi_q$ and $\chi_I$ also reflects the strong correlation between fluctuations in different flavor components. This will become clear
from our discussion of flavor diagonal and non-diagonal susceptibilities in the next section.

### 3.2 Flavor diagonal and non-diagonal susceptibilities

Using the relation between quark number and isovector susceptibilities on the one hand and diagonal and non-diagonal susceptibilities on the other hand (Eq. (2.10)) we also can define expansions for the latter,

\[
\frac{\chi_{uu}(T, \mu_q)}{T^2} = 2c_{uu}^2 + 12c_{uu}^4 \left( \frac{\mu_q}{T} \right)^2 + 30c_{uu}^6 \left( \frac{\mu_q}{T} \right)^4 + \cdots ,
\]

\[
\frac{\chi_{ud}(T, \mu_q)}{T^2} = 2c_{ud}^2 + 12c_{ud}^4 \left( \frac{\mu_q}{T} \right)^2 + 30c_{ud}^6 \left( \frac{\mu_q}{T} \right)^4 + \cdots ,
\]

with \(c_{uu}^n = (c_n + c_I^n)/4\) and \(c_{ud}^n = (c_n - c_I^n)/4\).

As discussed in the previous section the expansion coefficients \(c_n\) and \(c_I^n\) become quite similar at high temperature. This was to be expected from the discussion of the structure of the high temperature perturbative expansion given in section 2.1 as \(c_n\) and \(c_I^n\) differ only by contributions coming from non-diagonal susceptibilities, which enter with opposite sign in these two coefficients. It thus is instructive to analyze directly the expansion coefficients of \(\chi_{uu}\) and \(\chi_{ud}\). These are listed in Table 3.3 and plotted in Fig. (3.4). We note that the errors on these quantities have been obtained from an independent jackknife analysis and thus are not simply obtained by adding errors for \(c_n\) and \(c_I^n\).

Fig. (3.4) clearly shows that for \(T > T_0\) the various expansion coefficients rapidly approach the corresponding ideal gas values, which is zero for all non-diagonal expansion coefficients, \(c_{ud}^n\). In fact, as discussed in section 2.1 the latter receive contributions only at \(\mathcal{O}(g^n \ln 1/g^2)\) for \(n = 2\) and \(\mathcal{O}(g^3)\) for \(n > 2\). Moreover, it is interesting to note that despite the small magnitude of these contributions the leading order perturbative results correctly predict the sign of all expansion coefficients for \(T > T_0\), i.e. \(c_{ud}^{2,6} < 0\), \(c_{ud}^4 > 0\), and \(c_{uu}^{2,4} > 0\), \(c_{uu}^6 < 0\). Furthermore, the order of magnitude for \(c_{ud}^2\), i.e. \(|c_{ud}^2| \approx 5 \cdot 10^{-4}\) at \(T \approx 2T_0\), agrees with the perturbative estimate\(^1\) [22].

A striking feature of the expansion coefficients \(c_{uu}^n\) and \(c_{ud}^n\) is that for \(n > 2\) they become similar in magnitude close to \(T_0\). In fact, \(c_{uu}^4\) and \(c_{ud}^4\) both have pronounced peaks at \(T_0\) with \((c_{ud}^4/c_{uu}^4)_{\text{peak}} \approx 0.45\) and the expansion coefficients for \(n = 6\) are identical within errors. This suggests that any divergent piece in \(\chi_{uu}\), which could occur when \(\mu_q/T\) approaches the radius of convergence of the Taylor expansion, will show up with

---

\(^1\)A previous analysis [18] reported values for \(c_{ud}^2\) consistent with zero for temperatures \(T/T_0 \geq 1.25\) within an error of \(10^{-6}\). This has been found subsequently to be incorrect. The corrected values [20] are qualitatively consistent with our findings. (The second panel of Fig. 10 in [20] should be compared to twice the value of \(c_{ud}^2\) shown in our Fig. 3.4.) Similar agreement is found with the results of [19].
identical strength also in $\chi^{ud}$. This, in turn, implies that the singular behavior will add up constructively in the quark number susceptibility whereas it can cancel in the isovector susceptibility giving rise to finite values for $\chi_I$ at such a critical point. Even for smaller, non-critical values of $\mu_q/T$, however, the rapid rise of $c_n^{ud}(T)$ for $T \approx T_0$ is important. It shows that non-diagonal susceptibilities will become large at non-zero chemical potential in the transition region from the low to the high temperature phase, i.e. fluctuations in different flavor channels, which are uncorrelated at high temperature, become strongly correlated in the transition region. This correlation is also reflected in the errors of the various expansion coefficients, which are of similar size for $c_n^{uu}$ and $c_n^{ud}$ but much reduced in the difference, $\chi_I$.

The above considerations also suggest that the electric charge susceptibility,

$$
\chi_C = \left( \frac{2}{3} \frac{\partial}{\partial \mu_u} - \frac{1}{3} \frac{\partial}{\partial \mu_d} \right) \left( \frac{2}{3} \frac{\partial p}{\partial \mu_u} - \frac{1}{3} \frac{\partial p}{\partial \mu_d} \right) = \frac{1}{9} \left( 4\chi_{uu} + \chi_{dd} - 4\chi_{ud} \right) = \frac{1}{4} \left( \chi_I + \frac{1}{9} \chi_q \right),
$$

(3.9)

will be singular whenever the diagonal and non-diagonal susceptibilities are singular as

| $T/T_c$ | $c_2^{uu} \times 10^2$ | $c_4^{uu} \times 10^2$ | $c_6^{uu} \times 10^2$ | $c_2^{ud} \times 10^2$ | $c_4^{ud} \times 10^2$ | $c_6^{ud} \times 10^2$ |

Table 3.3: Taylor expansion coefficients $c_n^{uu}(T)$ and $c_n^{ud}(T)$. 
the cancellation between the corresponding singular parts will be incomplete. We show the charge susceptibility in Fig. (3.5). As it is dominated by the contribution from the isovector susceptibility any possible singular contribution arising from $\chi_q$ will be weak. It thus may not be too surprising that a peak does not yet show up in $\chi_C$.

### 3.3 Mass derivatives and chiral condensate

The transition between low and high temperature phases of strongly interacting matter is expected to be closely related to chiral symmetry restoration. It is therefore also of interest to analyze the dependence of the chiral condensate on the quark chemical potential. We will do so in the framework of a Taylor expansion of the grand potential, 

$$\frac{\langle \bar{\psi}\psi \rangle}{T^3} = \left( \frac{N_c}{N_f} \right) \frac{1}{3} \frac{\partial \ln Z}{\partial (\mu_q/T)} = \sum_{n=0}^{\infty} c_n^{\bar{\psi}\psi} (T) \left( \frac{\mu_q}{T} \right)^n ,$$  \hspace{1cm} (3.10)

with

$$c_n^{\bar{\psi}\psi} = \frac{1}{n!} \frac{\partial^n \langle \bar{\psi}\psi \rangle / T^3}{\partial (\mu_q/T)^n} \bigg|_{\mu_q=\mu_f=0} = \frac{1}{n!} \frac{\partial^{n+1} \Omega}{\partial (\mu_q/T)^n \partial m/T} \bigg|_{\mu_q=\mu_f=0} .$$  \hspace{1cm} (3.11)
Figure 3.5: The charge susceptibility $\chi_C/T^2$ as a function of $T/T_0$ for various $\mu_q/T$ ranging from $\mu_q/T = 0$ (lowest curve) rising in steps of 0.2 to $\mu_q/T = 1$, calculated from a Taylor series in 6th order.

Here we expressed the bare lattice quark masses, $m_a$, in units of the temperature by using $m/T \equiv maN_\tau$. For $n > 0$ the expansion coefficients of the chiral condensate, are directly related to derivatives of the expansion coefficients of the grand potential $\Omega$ with respect to the quark mass, i.e. $c_n^{\bar{\psi}\psi} = \partial c_n/\partial (m/T)$. For $n = 0$ this holds true up to a contribution arising from the normalization of the pressure at $(T = 0, \mu_q = 0)$. As such the coefficients $c_n^{\bar{\psi}\psi}$ also provide information on the quark mass dependence of other thermodynamic observables like pressure, number density or susceptibilities. For instance, the change of the quark number susceptibility with quark mass is given by

$$\frac{\partial \chi_q/T^2}{\partial m/T} = 2c_2^{\bar{\psi}\psi} + 12c_4^{\bar{\psi}\psi} \left( \frac{\mu_q}{T} \right)^2 + O(\mu_q^4).$$  \hspace{1cm} (3.12)

We have calculated the derivatives of $c_n$ with respect to the quark mass for $n = 0, 2$ and 4. These derivatives are shown in Fig. (3.6) together with the corresponding derivatives for the expansion coefficients of the isovector susceptibility, which have a similar temperature dependence,

$$\frac{\partial \chi_I/T^2}{\partial m/T} = 2c_2^{I,\bar{\psi}\psi} + 12c_4^{I,\bar{\psi}\psi} \left( \frac{\mu_q}{T} \right)^2 + O(\mu_q^4).$$  \hspace{1cm} (3.13)

We note that the expansion coefficients $c_n^{\bar{\psi}\psi}$ are negative for $n > 0$ and $T \leq 0.96T_0$. The chiral condensate thus will drop at fixed temperature with increasing $\mu_q/T$ and the chiral
susceptibilities will increase in the hadronic phase with decreasing quark mass. This, together with the change of sign in $c_4$ at $T \simeq T_0$, will shift the transition point at non-zero $\mu_q/T$ to lower temperatures. In Fig. (3.7) we show the chiral condensate and the related chiral susceptibility\(^\text{\textsuperscript{3}}\) obtained from a Taylor expansion up to and including $O(\mu_q^4)$,

\[
\chi_{\bar{\psi}\psi} \quad = \quad \frac{N_t}{N^3} \left( \frac{n_t}{4} \right)^2 \left[ \langle (\text{tr}M^{-1})^2 \rangle - \langle \text{tr}M^{-1} \rangle^2 \right] \\
= \quad c_0^\chi + c_2^\chi \left( \frac{\mu_q}{T} \right)^2 + c_4^\chi \left( \frac{\mu_q}{T} \right)^4 + O \left( \left( \frac{\mu_q}{T} \right)^6 \right). \quad (3.14)
\]

Obviously $\chi_{\bar{\psi}\psi}$ develops a much more pronounced peak for $\mu_q/T > 0$ than at vanishing chemical potential which, moreover, is shifted to smaller temperatures. However, as will become clear from the discussion in the next section the peaks found in $\chi_{\bar{\psi}\psi}$ and also in other susceptibilities have to be analyzed and interpreted carefully. They reflect the abrupt transition from the hadronic regime to the high temperature phase in which fluctuations of the chiral condensate are suppressed, but do not signal the presence of a 2\textsuperscript{nd} order phase transition unambiguously. The rapid rise of susceptibilities in the hadronic phase is strongly correlated to the increase in the pressure and is also present in a hadron gas which does not show any singular behavior at the transition temperature.

Also the expansion of the chiral condensate and related observables are compatible with the HRG model. In fact, a comparison of the temperature dependence of $c_4^{\bar{\psi}\psi}$ shown in Fig. (3.6) with that of the expansion coefficients $c_n$ of the grand potential shown in

\footnote{The chiral susceptibility introduced here is not the complete derivative of the chiral condensate with respect to the quark mass. As frequently done also at $\mu_q = 0$ we define the chiral susceptibility by ignoring a contribution from the connected part which would arise in the derivative $\partial \langle \bar{\psi}\psi \rangle / \partial m$. Nonetheless $\chi_{\bar{\psi}\psi}$ seems to capture the leading singular behavior that should show up at a 2\textsuperscript{nd} order critical point [30].}
Figure 3.7: The chiral condensate \( \langle \bar{\psi} \psi \rangle \) (left) and chiral susceptibility \( \chi_{\bar{\psi} \psi} \) (right) as a function of \( T/T_0 \) for \( \mu_q/T = 0, 0.4 \) and 0.8. The chiral condensate drops with increasing \( \mu_q/T \) and the peak in \( \chi_{\bar{\psi} \psi} \) becomes more pronounced.

Fig. (3.1) suggests a strong similarity between \(-c_n\bar{\psi}\psi\) and \(c_{n+2}\). On the other hand, for \( T < T_0 \) the ratio \( c_4\bar{\psi}\psi/c_2\bar{\psi}\psi \) agrees within errors with the ratio \( c_4/c_2 \) shown in Fig. (4.1). All this is consistent with the HRG model where the quark mass (or spectrum) dependence only enters through the functions \( F(T) \) and \( G(T) \) and does not modify the dependence on \( \mu_q/T \).

### 4 Radius of convergence and the hadron resonance gas

So far we have not discussed the range of validity of the Taylor expansion. In general the Taylor series will only converge for \( \mu_q/T < \rho \) (or \( \mu_q/T \leq \rho \)) where the radius of convergence, \( \rho \), is determined by the zero of \( Z(T,\mu_q,\mu_q) \) closest to the origin of the complex \( \mu_q \) plane. If this zero happens to lie on the real axis the radius of convergence coincides with a critical point of the QCD partition function. A sufficient condition for this is that all expansion coefficients are positive [31]. Apparently this is the case for all coefficients \( c_n(T) \) with \( T/T_0 < 0.96 \) that have been calculated so far by us\(^k\). Above \( T_0 \), however, we find from the calculation of \( c_6(T) \) that the expansion coefficients do not stay

\(^k\)In [20] it is reported that \( c_8(T) \) is negative for \( T < 0.95T_0 \), however, the statistical significance of this result unfortunately is not given.
strictly positive. This is in accordance with our expectation to find a chiral critical point
at some temperature $T < T_0$.

The radius of convergence of the Taylor series for $\Omega(T, \mu_q, \mu_\bar{q})$ can be estimated by
inspecting ratios of subsequent expansion coefficients,

$$\rho = \lim_{n \to \infty} \sqrt[n]{\frac{c_{2n}}{c_{2n+2}}},$$  \hspace{1cm} (4.1)

where the square root arises because the Taylor expansion of the grand potential $\Omega$ is an
even series in $\mu_q/T$. The ratios $c_{2n+2}/c_{2n}$ are shown in Fig. (4.1) together with ratios of
the expansion coefficients $c_{2n}^I$ of the isovector susceptibility and $c_{2n}^{\bar{\psi}\bar{\psi}}$ of the chiral condensate. It is obvious that these ratios rapidly change across $T_0$ and approach the value of corresponding ratios obtained in the high temperature ideal gas limit. Another remarkable feature, however, is that below $T_0$ the ratios involving expansion coefficients of the $\mu_q$-dependent parts of $\Omega$, $\chi_I$ and $\chi_{\bar{\psi}\bar{\psi}}$ are almost temperature independent. In fact, these ratios are consistent with the corresponding ratios deduced from the grand potential of a hadron resonance gas (Eq. (2.23)), i.e. $c_4/c_2 = c_4^{\bar{\psi}\bar{\psi}}/c_2^{\bar{\psi}\bar{\psi}} = 3/4$ and $c_6/c_4 = c_6^{I}/c_4^{I} = 3/10$.

In ratios that contain the lowest order expansion coefficients, i.e. $c_0$, $c_0^{\bar{\psi}\bar{\psi}}$ and $c_2^I$, the spectrum dependence does not cancel because the lowest order expansion coefficients also depend on the meson sector which is not the case for higher order coefficients. These ratios thus show a significant temperature dependence as can be seen for $c_4^{I}/c_2^{I}$ and $c_6^{\bar{\psi}\bar{\psi}}/c_4^{\bar{\psi}\bar{\psi}}$ shown in Fig. (4.1).

Similar information is contained in the ratios of physical observables, e.g. the quark
number density or pressure over the quark number susceptibility, introduced in Eq. (2.20). These ratios are shown in Fig. (4.2). Here $n_q/T^3$ and $\chi_q/T^2$ have been calculated using
Figure 4.2: The baryonic part of the pressure divided by the quark number susceptibility, \( \Delta p/\chi_q \) (left), and the normalized derivative of pressure with respect to quark number density, \( n_q/\chi_q \) (right), as a function of \( \mu_q/T \) for various \( T/T_0 \). Horizontal lines show the infinite temperature ideal gas values and the HRG model prediction \( (T \leq T_0) \) (solid lines) and expanded to 6th-order in \( \mu_q/T \) (dashed lines). The difference is visible only for \( \Delta p/\chi_q \) at \( \mu_q/T = 0.8 \).

Eqs. (3.3) and (3.4) up to \( \mathcal{O}(\mu_q^6) \). The ratio, \( n_q/\chi_q = (\partial p/\partial \mu_q)/(\partial n_q/\partial \mu_q) = \partial p/\partial n_q \) is related to the isothermal compressibility, \( \kappa_T = \chi_q/n_q^2 \) which diverges at a 2nd order phase transition point, i.e. at a point at which \( \partial p/\partial n_q = 0 \), the number of particles is unstable under small changes in the pressure (mechanical instability) and large density fluctuations occur. This instability leads to a divergence in the quark number susceptibility [21]. A 2nd order phase transition is thus expected to be signalled by a zero in both ratios shown in Fig. 4.2. On the other hand, for \( \mu_I = 0 \) these ratios are expected to be constant in an ideal quark-gluon plasma as well as in a hadron resonance gas,

\[
\frac{n_q^{SB}}{\mu_q \chi_q^{SB}} = \frac{1 + \frac{1}{\pi^2} \left( \frac{\mu_q}{T} \right)^2}{1 + \frac{3}{\pi^2} \left( \frac{\mu_q}{T} \right)^2}, \quad \frac{n_q^{HRG}}{\mu_q \chi_q^{HRG}} = \frac{T}{3 \mu_q} \tanh \left( \frac{3 \mu_q}{T} \right). \tag{4.2}
\]

The corresponding values are indicated in Fig. 4.2 by horizontal lines.

As far as the determination of a possible 2nd order critical point at non-vanishing quark chemical potential (chiral critical point) is concerned Fig. 4.1 and Fig. 4.2 contain identical information. For \( T \leq 0.96T_0 \) bulk thermodynamic observables agree with predictions based on an HRG model, which in itself does not show any critical behavior as function of \( \mu_q/T \) at fixed \( T \). In particular, there is no hint for a dip in \( \Delta p/\chi_q \) or \( n_q/\chi_q \) which could signal the presence of a second order transition point. The
same observation, albeit with larger statistical errors, holds for ratios involving the chiral susceptibility $\chi_{\bar{\psi}\psi}$. Nonetheless, all these quantities change rapidly in the transition from the low temperature to the high temperature regime and, moreover, at $T = T_0$ the 6th order expansion coefficients clearly cannot be described within the HRG model. Due to the good agreement with the HRG model and its Taylor expansion at lower temperature we cannot, however, present an upper limit for the radius of convergence below $T_0$; the ratios shown in Fig. [41] suggest that a lower limit is given by $(\mu_q/T)_c > 1$. Also from the analysis of the temperature dependence of bulk thermodynamic observables we get, at present, no unambiguous evidence for the existence of a phase transition. At present, therefore, we cannot rule out that in the temperature range covered by our analysis ($T > 0.8T_0$) the transition to the high temperature phase is a rapid crossover transition rather than a phase transition. This situation then would be similar to that at $\mu_q = 0$. In order to exclude this possibility we would need, in the future: to consider even higher orders in the Taylor series; to scan in more detail the small temperature interval $[0.95T_0, T_0]$; and to explore systematically the quark mass and volume dependence of our results. These issues are partially addressed already in the next section where we discuss the use of reweighting techniques to calculate some thermodynamic observables and compare results obtained within this approach with results from the Taylor expansion.

The good agreement found here for different ratios of Taylor expansion coefficients calculated on the lattice and within the HRG model suggests that we may use this information for a more detailed analysis of the composition of hadronic matter at temperatures below $T_0$. In Ref. [15] also the temperature dependence of thermodynamic observables like the pressure or the quark number susceptibility have been compared to the HRG model. In order to do so the hadron spectrum has been adjusted to the conditions realized in the lattice calculations, i.e. all masses have been shifted to larger values as the lattice calculations have been performed with unphysically large quark masses. This approach can also be turned around. The HRG model for $T < T_0$ can be used as an ansatz to determine the contributions of the mesonic and baryonic parts of the spectrum without making assumptions on the distortion of the spectrum due to the unphysical quark mass values.

As outlined in section 2, within the Boltzmann approximation the HRG model yields a simple dependence of the pressure on the quark chemical potential. The relation given in Eq. [2.15] can easily be extended to also include a non-vanishing isovector chemical potential. Neglecting the mass difference among isospin partners the pressure can be written as,

$$\frac{p(T, \mu_q, \mu_I)}{T^4} \approx G^{(1)}(T) + G^{(3)}(T) \frac{1}{3} \left( 2 \cosh \left( \frac{2\mu_I}{T} \right) + 1 \right)$$

\[\text{For these observables a good functional agreement between lattice data and the leading } \mu_q \text{ dependent term in the HRG model has also been noted in [14] within the imaginary chemical potential approach.}\]
Figure 4.3: Contribution of different hadronic channels to the total pressure $p/T^4$ obtained by using the HRG ansatz. Shown are results for (a) $\mu_q/T = 0$, (b) $\mu_q/T = 0.4$ and (c) $\mu_q/T = 0.8$.

\[ G^{(1)}(T) = 3 \frac{c_2}{4} - c_4^I, \quad F^{(2)}(T) = \frac{5}{18} c_2 - \frac{2}{3} c_4^I, \quad F^{(4)}(T) = -\frac{1}{18} c_2 + \frac{2}{3} c_4^I. \]  

The various contributions to the pressure are shown in Fig. (4.3)a for $\mu_q = 0$. With increasing quark chemical potential the relative weight of hadrons in different quantum number channels changes. As expected the baryonic component becomes more important with increasing $\mu_q$ (Fig. (4.3)b and c). We find that for $\mu_q/T \gtrsim 0.6$ the baryonic sector gives the dominant contribution.
Figure 5.1: Contour plot of the variance of the phase of the quark determinant, $\sigma(\theta)$ calculated for $\theta^{(3)}$ in the $(T/T_0, \mu_q/T)$ plane. Contour lines for $\sigma(\theta^{(3)})$ are given in steps of $\pi/4$ ranging from $\pi/4$ (lowest curve) to $2\pi$.

5 Reweighting Approach

An alternative to a strict Taylor expansion of thermodynamic observables in terms of $\mu_q/T$ is the reweighting approach. Here the dependence of the grand potential on the quark chemical potential is included in the calculation of observables, $X$, by shifting the $\mu_q$-dependent piece of the QCD action into the calculation of expectation values rather than taking it into account in the statistical weights used for the generation of gauge field configurations. This reweighting approach has been used to analyze the thermodynamics of QCD at non-zero chemical potential [10, 12]. Within this approach thermodynamic observables $X(\beta, \mu)$ are estimated via the expression

$$\langle X \rangle_{(\beta, \mu)} = \frac{\langle X e^{\frac{4i}{\beta} \Delta \ln \det M} e^{-\Delta S_g} \rangle_{(\beta_0, 0)}}{\langle e^{\frac{4i}{\beta} \Delta \ln \det M} e^{-\Delta S_g} \rangle_{(\beta_0, 0)}},$$

(5.1)

where $\Delta \ln \det M \equiv \ln \det M(\mu) - \ln \det M(0)$ and $\Delta S_g \equiv S_g(\beta) - S_g(\beta_0)$ is the difference of the gluonic part of the QCD action. The expectation values on the RHS of Eq. (5.1) are obtained in simulations at $(\beta_0, 0)$. In [3] we implemented a version of Eq. (5.1) in which the reweighting factor $\Delta \ln \det M$ as well as the operator $X$ itself have been replaced by a Taylor series about $\mu = 0$. The advantage over an exact evaluation of $\det M$ [2] clearly is that the required expressions are calculable with relatively little computational effort even on large lattices. In our initial study we performed the expansion consistently up
The effectiveness of any reweighting approach strongly depends on the overlap between the ensemble simulated at $(\beta_0, \mu_0 = 0)$ and that corresponding to the true equilibrium state at $(\beta, \mu)$ which one wants to analyze. This can be judged by inspecting the average phase factor of the complex valued quark determinant, $\langle e^{i\theta}\rangle_{(\beta_0,0)}$, where the quark determinant is written as $\det M = |\det M|e^{i\theta}$. Reweighting loses its reliability once $\langle e^{i\theta}\rangle \ll 1$ as both expectation values appearing in the numerator and denominator of Eq. (5.1) then become difficult to control [32]. In our approach we estimate the phase factor via the variance of the phase $\theta$, $\sigma(\theta) = \sqrt{\langle \theta^2 \rangle - \langle \theta \rangle^2}$, where we approximate the phase by its Taylor expansion up to $O(\mu^{2n-1})$,

$$\theta^{(n)} = \frac{\mu^0}{4} \text{Im} \sum_{j=1}^{n} \frac{\mu^{2j-1}}{(2j-1)!} \partial^{2j-1} \ln \det M \partial_{\mu^{2j-1}}.$$

As discussed and shown in Fig. 6 of [32], the value of $\mu_q/T$ for which the standard deviation of $\theta^{(n)}$ exceeds $\pi/2$ is a reasonable criterion for judging the applicability of reweighting.
in our simulated systems. In Fig. (5.1) we show contour lines for the variance of $\theta^{(3)}$. All contour lines drop dramatically in the vicinity of $T_0$; the contour corresponding to $\sigma(\theta^{(3)}) = \pi/2$ yields $\mu_q/T \approx 1.5$ at $T \simeq 1.2T_0$ and reaches a minimum value of about 0.6 at $T \simeq 0.9T_0$. Reweighting is thus much easier to control in the high temperature phase than in the hadronic phase.

In Fig. (5.2) we plot quark number and isovector susceptibilities for various $\mu_q/T$ calculated by using reweighting where possible. The operators needed for the susceptibilities are calculated with an error of $O(\mu^6)$, the reweighting factor $\Delta \ln \det M$ with error $O(\mu^8)$. Dashed lines show a comparison with the results obtained from direct Taylor expansion of the susceptibilities up to and including $O(\mu^4)$ (see Fig. (3.3)).

As anticipated above, for $T < T_0$ reweighting becomes difficult to control for $\mu_q/T > 0.6$. However, where reweighting appears to be statistically under control, it agrees well with the direct Taylor expansion and even shows similar features in the statistical errors; i.e. the signal is much noisier in the vicinity of $T_0$ for $\chi_q$ than for $\chi_I$.

6 Conclusions

We have extended our analysis of the thermodynamics of two flavor QCD at non-zero quark chemical potential to the 6th order in a Taylor expansion around $\mu_q/T = 0$. We find clear evidence for a rapid transition from a low temperature hadronic phase to a high temperature quark-gluon plasma phase which is signalled by large fluctuations in the quark number density and the chiral condensate. The transition temperature shifts to smaller values with increasing quark chemical potential. Above $T_0$ the Taylor expansion coefficients and bulk thermodynamic observables agree with qualitative features of the perturbative high temperature expansion and approach the ideal gas limit to within $\sim 20\%$ for $T \gtrsim 1.5T_0$. Thermodynamics in the low temperature phase agrees well with predictions based on a hadron resonance gas for temperatures $T \lesssim 0.96T_0$ and $\mu_q/T \lesssim 1$.

From the analysis of bulk thermodynamic observables alone we cannot provide strong evidence for the existence of a 2nd order phase transition point in the QCD phase diagram. At present we cannot rule out the transition being a rapid crossover in the entire parameter space covered by our analysis. In particular, we have shown that large fluctuations in the quark number and the chiral condensate are consistent with expectations based on a hadron resonance gas. The current estimates on the radius of convergence of the Taylor expansion favor a critical value of the quark chemical potential close to $\mu_q \approx T_0$. The good agreement of the expansion coefficients with those of a hadron gas, however, prohibit any firm conclusion on the location and even on the existence of the chiral critical point.

Likewise, we cannot rule out that a 2nd order transition occurs at temperatures closer to $T_0$ than the largest value in the hadronic phase, $T = 0.96T_0$ which we have analyzed
here. In order to improve on the current analysis it would be important to perform calculations at smaller quark masses in a narrower temperature interval around $T_0$. An improvement over the current statistical errors on the $6^{th}$ order coefficient as well as the analysis of higher order expansion coefficients with high statistics is needed.

A Appendix: Taylor expansion coefficients

In this appendix, we derive some equations which are used in the calculation of the various thermodynamic quantities and expansion coefficients of the Taylor series presented in this study. The partition function is given by

$$ Z = \int \mathcal{D}U (\det M)^{n_f/4} e^{-S_g}, \quad (A.1) $$

with $U \in SU(3)$. The expectation value of a physical quantity, $\langle \mathcal{O} \rangle$ is then obtained as

$$ \langle \mathcal{O} \rangle = \frac{1}{Z} \int \mathcal{D}U \mathcal{O} (\det M)^{n_f/4} e^{-S_g}, \quad (A.2) $$

and its derivatives with respect to quark chemical potential and quark mass are given by,

$$ \frac{\partial \langle \mathcal{O} \rangle}{\partial \mu} = \left\langle \frac{\partial \mathcal{O}}{\partial \mu} \right\rangle + \frac{n_f}{4} \left( \left\langle \mathcal{O} \frac{\partial (\ln \det M)}{\partial \mu} \right\rangle - \langle \mathcal{O} \rangle \left\langle \frac{\partial (\ln \det M)}{\partial \mu} \right\rangle \right), \quad (A.3) $$

$$ \frac{\partial \langle \mathcal{O} \rangle}{\partial m} = \left\langle \frac{\partial \mathcal{O}}{\partial m} \right\rangle + \frac{n_f}{4} \left( \left\langle \mathcal{O} \frac{\partial (\ln \det M)}{\partial m} \right\rangle - \langle \mathcal{O} \rangle \left\langle \frac{\partial (\ln \det M)}{\partial m} \right\rangle \right) $$

$$ = \left\langle \frac{\partial \mathcal{O}}{\partial m} \right\rangle + \frac{n_f}{4} \left( \left\langle \mathcal{O} \text{tr} M^{-1} \right\rangle - \langle \mathcal{O} \rangle \left\langle \text{tr} M^{-1} \right\rangle \right). \quad (A.4) $$

Here we use $m$ as the dimensionless quark mass value instead of $m_a$, and also $\mu = \mu_q a$ for the dimensionless quark chemical potential. The temperature is $T = (N_f a)^{-1}$ and the volume is $V = (N_f a)^3$. Moreover, we introduce for simplification,

$$ C_n = \frac{n_f}{4} \frac{\partial^n \text{tr} M^{-1}}{\partial \mu^n} = \frac{n_f}{4} \frac{\partial^{n+1} \ln \det M}{\partial \mu^{n+1}} \quad \text{and} \quad D_n = \frac{n_f}{4} \frac{\partial^n \ln \det M}{\partial \mu^n}. \quad (A.5) $$
All Taylor expansion coefficients used in this paper can be expressed in terms of expectation values of certain combinations of $C_n$ and $\mathcal{D}_n$. The required derivatives of $\ln \det M$ and $\text{tr} M^{-1}$ are explicitly given in the following.

**Derivatives of $\ln \det M$:**

\[
\frac{\partial \ln \det M}{\partial \mu} = \text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} \right), \tag{A.6}
\]

\[
\frac{\partial^2 \ln \det M}{\partial \mu^2} = \text{tr} \left( M^{-1} \frac{\partial^2 M}{\partial \mu^2} \right) - \text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} \right), \tag{A.7}
\]

\[
\frac{\partial^3 \ln \det M}{\partial \mu^3} = \text{tr} \left( M^{-1} \frac{\partial^3 M}{\partial \mu^3} \right) - 3\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^2 M}{\partial \mu^2} \right) + 2\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} \right), \tag{A.8}
\]

\[
\frac{\partial^4 \ln \det M}{\partial \mu^4} = \text{tr} \left( M^{-1} \frac{\partial^4 M}{\partial \mu^4} \right) - 4\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^3 M}{\partial \mu^3} \right) - 3\text{tr} \left( M^{-1} \frac{\partial^2 M}{\partial \mu^2} M^{-1} \frac{\partial^2 M}{\partial \mu^2} \right) + 12\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^2 M}{\partial \mu^2} \right) - 6\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} \right), \tag{A.9}
\]

\[
\frac{\partial^5 \ln \det M}{\partial \mu^5} = \text{tr} \left( M^{-1} \frac{\partial^5 M}{\partial \mu^5} \right) - 5\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^4 M}{\partial \mu^4} \right) - 10\text{tr} \left( M^{-1} \frac{\partial^2 M}{\partial \mu^2} M^{-1} \frac{\partial^3 M}{\partial \mu^3} \right) + 20\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^3 M}{\partial \mu^3} \right) + 30\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^2 M}{\partial \mu^2} M^{-1} \frac{\partial^2 M}{\partial \mu^2} \right) - 60\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} \right) + 24\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} \right), \tag{A.10}
\]

\[
\frac{\partial^6 \ln \det M}{\partial \mu^6} = \text{tr} \left( M^{-1} \frac{\partial^6 M}{\partial \mu^6} \right) - 6\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^5 M}{\partial \mu^5} \right) - 15\text{tr} \left( M^{-1} \frac{\partial^2 M}{\partial \mu^2} M^{-1} \frac{\partial^4 M}{\partial \mu^4} \right) - 10\text{tr} \left( M^{-1} \frac{\partial^3 M}{\partial \mu^3} M^{-1} \frac{\partial^3 M}{\partial \mu^3} \right) + 30\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^4 M}{\partial \mu^4} \right) + 60\text{tr} \left( M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^2 M}{\partial \mu^2} M^{-1} \frac{\partial^3 M}{\partial \mu^3} \right) + 60\text{tr} \left( M^{-1} \frac{\partial^2 M}{\partial \mu^2} M^{-1} \frac{\partial M}{\partial \mu} M^{-1} \frac{\partial^3 M}{\partial \mu^3} \right) + 30\text{tr} \left( M^{-1} \frac{\partial^2 M}{\partial \mu^2} M^{-1} \frac{\partial^2 M}{\partial \mu^2} M^{-1} \frac{\partial^2 M}{\partial \mu^2} \right).\]
Having defined the explicit representation of $C_n$ and $D_n$ we now can proceed to define the expansion coefficients for various thermodynamic quantities discussed in this paper.
Pressure \( (p) \): The pressure is obtained from the logarithm of the QCD partition function. Its expansion is defined in Eqs. (3.1) and (3.2). The leading expansion coefficient \( c_0 \) is given by the pressure calculated at \( \mu_q = 0 \). All higher order expansion coefficients are given in terms of derivatives of \( \ln Z \).

\[
\frac{p}{T^4} \equiv \Omega = \frac{1}{V T^3} \ln Z = \sum_{n=0}^{\infty} c_n \left( \frac{\mu_q}{T} \right)^n ,
\]
(A.16)

with

\[
c_n = \left. \frac{1}{n! V T^3} \frac{\partial^n \ln Z}{\partial (\mu_q/T)^n} \right|_{\mu=0}.
\]
(A.17)

To generate the expansion we first consider derivatives of \( \ln Z \) for \( \mu \neq 0 \). For the first derivative we find

\[
\frac{\partial \ln Z}{\partial \mu} \equiv A_1 = \langle D_1 \rangle .
\]
(A.18)

Higher order derivatives are generated using the relation

\[
\frac{\partial A_n}{\partial \mu} = A_{n+1} - A_n A_1 ,
\]
(A.19)

where \( A_n \) is defined as

\[
A_n \equiv \left\langle \exp\{-D_0\} \frac{\partial^n \exp\{D_0\}}{\partial \mu^n} \right\rangle .
\]
(A.20)

With this we can generate higher order derivatives of \( \ln Z \) iteratively using

\[
\frac{\partial^{n+1} \ln Z}{\partial \mu^{n+1}} = \frac{\partial^n A_1}{\partial \mu^n} .
\]
(A.21)

Explicitly we find from Eq. (A.20)

\[
A_2 = \langle D_2 \rangle + \langle D_1^2 \rangle ,
\]
(A.22)
\[
A_3 = \langle D_3 \rangle + 3 \langle D_2 D_1 \rangle + \langle D_1^3 \rangle ,
\]
(A.23)
\[
A_4 = \langle D_4 \rangle + 4 \langle D_3 D_1 \rangle + 3 \langle D_2^2 \rangle + 6 \langle D_2 D_1^2 \rangle + \langle D_1^4 \rangle ,
\]
(A.24)
\[
A_5 = \langle D_5 \rangle + 5 \langle D_4 D_1 \rangle + 10 \langle D_3 D_2 \rangle + 10 \langle D_3 D_1^2 \rangle + 15 \langle D_2^2 D_1 \rangle + 10 \langle D_2 D_1^3 \rangle + \langle D_1^5 \rangle ,
\]
(A.25)
\[
A_6 = \langle D_6 \rangle + 6 \langle D_5 D_1 \rangle + 15 \langle D_4 D_2 \rangle + 10 \langle D_4 D_1^2 \rangle + 15 \langle D_3 D_2^2 \rangle + 60 \langle D_3 D_2 D_1 \rangle + 15 \langle D_3 D_1^3 \rangle + 20 \langle D_2^3 D_1 \rangle + 45 \langle D_2^2 D_1^2 \rangle + 15 \langle D_2 D_1^4 \rangle + \langle D_1^6 \rangle .
\]
(A.26)
From Eq. (A.21) we then obtain through repeated application of Eq. (A.19),

\[
\frac{\partial \ln Z}{\partial \mu} = A_1, \quad (A.27)
\]
\[
\frac{\partial^2 \ln Z}{\partial \mu^2} = A_2 - A_1^2, \quad (A.28)
\]
\[
\frac{\partial^3 \ln Z}{\partial \mu^3} = A_3 - 3A_2A_1 + 2A_1^3, \quad (A.29)
\]
\[
\frac{\partial^4 \ln Z}{\partial \mu^4} = A_4 - 4A_3A_1 - 3A_2^2 + 12A_2A_1^2 - 6A_1^4, \quad (A.30)
\]
\[
\frac{\partial^5 \ln Z}{\partial \mu^5} = A_5 - 5A_4A_1 - 10A_3A_2 + 20A_3A_1^2 + 30A_2^2A_1 - 60A_2A_1^3 + 24A_1^5, \quad (A.31)
\]
\[
\frac{\partial^6 \ln Z}{\partial \mu^6} = A_6 - 6A_5A_1 - 15A_4A_2 - 10A_3^2 + 30A_4A_1^2 + 120A_3A_2A_1 + 30A_2^3 - 120A_3A_1^3 - 270A_2^2A_1^2 + 360A_2A_1^4 - 120A_1^6. \quad (A.32)
\]

These relations simplify considerably for \(\mu = 0\) as all odd expectation values vanish, \textit{i.e.} \(A_n = 0\) for \(n\) odd. In fact, \(\partial^n (\ln \det M) / \partial \mu^n\) is strictly real for \(n\) even and pure imaginary for \(n\) odd. Using this property, the odd derivatives of the pressure vanish and also the even derivatives become rather simple. This defines the expansion coefficients \(c_n\) introduced in Eqs. (3.1) and (3.2).

\[
c_2 \equiv \frac{1}{2} \frac{\partial^2 (p/T^4)}{\partial (\mu_q/T)^2} \bigg|_{\mu_q=0} = \frac{1}{2} \frac{N_c}{N_f^2} A_2 ,
\]
\[
c_4 \equiv \frac{1}{4!} \frac{\partial^4 (p/T^4)}{\partial (\mu_q/T)^4} \bigg|_{\mu_q=0} = \frac{1}{4!} \frac{1}{N_f^3 N_c} (A_4 - 3A_2^2) ,
\]
\[
c_6 \equiv \frac{1}{6!} \frac{\partial^6 (p/T^4)}{\partial (\mu_q/T)^6} \bigg|_{\mu_q=0} = \frac{1}{6!} \frac{1}{N_f^3 N_c^3} (A_6 - 15A_4A_2 + 30A_2^3) . \quad (A.33)
\]

Here all expectation values \(A_n\) are now meant to be evaluated at \(\mu = 0\).

\textbf{Isovector susceptibility} \((\chi_I)\): While the Taylor expansion of the quark number susceptibility is easily obtained from that of the pressure we need to introduce the expansion of the isovector susceptibility. This has been done in Eq. (3.5). More explicitly the isovector susceptibility is given by

\[
\frac{\chi_I}{T^2} = \frac{N_f}{N_f^3} \frac{N_c}{N_f^2} \left( \frac{\partial^2 \ln Z}{\partial \mu^2} \right) - \left( \frac{\partial^2 \ln Z}{\partial \mu_u \partial \mu_d} + \frac{\partial^2 \ln Z}{\partial \mu_d^2} \right) \bigg|_{\mu_q=0} + \left( \frac{1}{4} \frac{\partial (\ln \det M_f)}{\partial \mu_u} - \frac{1}{4} \frac{\partial (\ln \det M_u)}{\partial \mu_u} \right)^2 \bigg|_{\mu_q=0} \bigg|_{\mu_q=0}
\]

33
\[ - \left\langle \frac{1}{4} \frac{\partial (\ln \det M_u)}{\partial \bar{\mu}_u} - \frac{1}{4} \frac{\partial (\ln \det M_d)}{\partial \bar{\mu}_d} \right\rangle^2 \]. \quad (A.34)

Throughout this paper we have considered the case of \( \bar{\mu}_u = \bar{\mu}_d \equiv \mu_q \equiv \mu \). The isovector chemical potential \( \mu_I \) has been set equal to zero after appropriate derivatives have been taken. In the Taylor expansions of \( \chi_I \), which is performed at \( \mu = 0 \) in terms of \( \mu_q/T \), the derivatives with respect to \( \mu_u \) and \( \mu_d \) then become identical, i.e.

\[ (\partial^n (\ln \det M_u) / \partial \mu^n_u) (\bar{\mu}_u u) \equiv (\partial^n (\ln \det M) / \partial \mu^n)(\mu). \]

The calculation of the isovector susceptibility thus reduces to the calculation of

\[ \frac{\chi_I}{T^2} = \frac{N_r}{2N_o^5} \left\langle \frac{\partial^2 (\ln \det M)}{\partial \mu^2} \right\rangle. \quad (A.35) \]

To define the expansion of the isovector susceptibility, \( \chi_I \) at fixed \( \mu_I = 0 \) around \( \mu_q = 0 \) we set up an iterative scheme similar to that introduced for the pressure. We introduce the additional kernel \( D_2 \) in Eq. (A.20) to generate \( B_n \) for arbitrary \( \mu_q \neq 0 \),

\[ B_{n+2} \equiv \left\langle \exp\{-D_0\} \frac{\partial^n D_2 \exp\{D_0\}}{\partial \mu^n} \right\rangle. \quad (A.36) \]

This yields,

\[
\begin{align*}
B_2 & = \langle D_2 \rangle, \\
B_3 & = \langle D_3 \rangle + \langle D_2 D_1 \rangle, \\
B_4 & = \langle D_4 \rangle + 2 \langle D_3 D_1 \rangle + \langle D_2^2 \rangle + \langle D_2 D_1^2 \rangle, \\
B_5 & = \langle D_5 \rangle + 3 \langle D_4 D_1 \rangle + 4 \langle D_3 D_2 \rangle + 3 \langle D_3^2 \rangle + 3 \langle D_2^2 D_1 \rangle + \langle D_2 D_1^2 \rangle, \\
B_6 & = \langle D_6 \rangle + 4 \langle D_5 D_1 \rangle + 7 \langle D_4 D_2 \rangle + 4 \langle D_3^2 \rangle + 6 \langle D_4 D_1^2 \rangle + 16 \langle D_3 D_2 D_1 \rangle + 3 \langle D_2^3 \rangle + 4 \langle D_3 D_1^3 \rangle + 6 \langle D_2^2 D_1^2 \rangle + \langle D_2 D_1^4 \rangle. 
\end{align*}
\]

The derivative of \( B_n \) with respect to the chemical potential satisfies,

\[ \frac{\partial B_n}{\partial \mu} = B_{n+1} - B_n A_1. \quad (A.42) \]

Starting with \( (N_r/N_o^5)B_2 = \chi_I/T^2 \), we obtain the equations for \( \partial^n (\chi_I/T^2)/\partial (\mu_q/T)^n \) iteratively, and then use again the CP symmetry for \( \mu = 0 \), i.e. \( A_n \) and \( B_n \) are zero for \( n \).
odd. Therefore the odd derivatives in the expansion of \( \chi I / T^2 \) at \( \mu = 0 \) are zero and the even derivatives define the expansion coefficients \( c_n^I \) used in Eq. (3.5),

\[
c_2^I \equiv \frac{1}{2} \left. \frac{\chi I}{T^2} \right|_{\mu_q = 0} \equiv \frac{1}{2} \frac{N_\tau}{N_\sigma^2} B_2 ,
\]
\[
c_4^I \equiv \frac{1}{4!} \left. \frac{\partial^2 (\chi I / T^2)}{\partial (\mu_q / T)^2} \right|_{\mu_q = 0} \equiv \frac{1}{4!} \frac{1}{N_\tau^2 N_\sigma^2} (B_4 - B_2 A_2),
\]
\[
c_6^I \equiv \frac{1}{6!} \left. \frac{\partial^4 (\chi I / T^2)}{\partial (\mu_q / T)^4} \right|_{\mu_q = 0} \equiv \frac{1}{6!} \frac{1}{N_\tau^3 N_\sigma^3} (B_6 - 6B_4 A_2 - B_2 A_4 + 6B_2 A_2^2) \quad . \tag{A.43}
\]

**Chiral condensate \( \langle \bar{\psi} \psi \rangle \) and disconnected chiral susceptibility \( \chi \bar{\psi} \psi \):** We also discuss the Taylor expansion of the chiral condensate and the related chiral susceptibility,

\[
\frac{\langle \bar{\psi} \psi \rangle}{T^3} = \frac{N_\tau^2}{N_\sigma^2} \frac{\partial \ln Z}{\partial m} = \frac{N_\tau^2}{N_\sigma^2} \frac{n_f}{4} \left( \frac{\partial \ln \det M}{\partial m} \right) = \frac{N_\tau^2}{N_\sigma^2} \frac{n_f}{4} \left( \langle \text{tr} M^{-1} \rangle \right) , \tag{A.44}
\]
\[
\frac{\chi \bar{\psi} \psi}{T^2} = \frac{N_\tau}{N_\sigma} \left( \frac{n_f}{4} \right)^2 \left[ \left( \langle \text{tr} M^{-1} \rangle \right)^2 - \langle \text{tr} M^{-1} \rangle \right] . \tag{A.45}
\]

The iterative scheme is similar to that introduced for the isovector susceptibility but with the generating kernel \( D_2 \) in Eq. (A.36) replaced by \( C_0 \). This yields

\[
F_0 = \langle C_0 \rangle , \tag{A.46}
\]
\[
F_1 = \langle C_1 \rangle + \langle C_0 D_1 \rangle , \tag{A.47}
\]
\[
F_2 = \langle C_2 \rangle + 2 \langle C_1 D_1 \rangle + \langle C_0 D_2 \rangle + \langle C_0 D_1^2 \rangle , \tag{A.48}
\]
\[
F_3 = \langle C_3 \rangle + 3 \langle C_2 D_1 \rangle + 3 \langle C_1 D_2 \rangle + \langle C_0 D_3 \rangle + 3 \langle C_1 D_1^2 \rangle + 3 \langle C_0 D_2 D_1 \rangle + \langle C_0 D_1^2 \rangle , \tag{A.49}
\]
\[
F_4 = \langle C_4 \rangle + 4 \langle C_3 D_1 \rangle + 6 \langle C_2 D_2 \rangle + 4 \langle C_1 D_3 \rangle + \langle C_0 D_4 \rangle + 6 \langle C_2 D_1^2 \rangle + 12 \langle C_1 D_2 D_1 \rangle + 4 \langle C_0 D_3 D_1 \rangle + 3 \langle C_0 D_2^2 \rangle + 4 \langle C_1 D_1^3 \rangle + 6 \langle C_0 D_2 D_1^2 \rangle + \langle C_0 D_1^3 \rangle . \tag{A.50}
\]

These expectation values again satisfy

\[
\frac{\partial F_n}{\partial \mu} = F_{n+1} - F_n A_1 \quad . \tag{A.51}
\]
This gives the expansion coefficients $c_{\tilde{\psi}\psi}^n$ for the chiral condensate defined in Eqs. (3.10) and (3.11),

\[
c_0^{\tilde{\psi}\psi} & \equiv \frac{\langle \tilde{\psi}\psi \rangle}{T^3} \bigg|_{\mu_q=0} = \frac{N_f^2}{N^3} F_0 , \tag{A.52}
\]

\[
c_2^{\tilde{\psi}\psi} & \equiv \frac{1}{2} \frac{\partial^2 \langle \tilde{\psi}\psi \rangle / T^3}{\partial (\mu_q/T)^2} \bigg|_{\mu_q=0} = \frac{1}{2} \frac{1}{N_f^2} \frac{\partial^2 \langle \tilde{\psi}\psi \rangle / T^3}{\partial \mu^2} \bigg|_{\mu=0} \\
& = \frac{1}{2} \frac{1}{N_f^3} (F_2 - F_0 A_2) , \tag{A.53}
\]

\[
c_4^{\tilde{\psi}\psi} & \equiv \frac{1}{4!} \frac{\partial^4 \langle \tilde{\psi}\psi \rangle / T^3}{\partial (\mu_q/T)^4} \bigg|_{\mu_q=0} = \frac{1}{4!} \frac{1}{N_f^3} \frac{\partial^4 \langle \tilde{\psi}\psi \rangle / T^3}{\partial \mu^4} \bigg|_{\mu=0} \\
& = \frac{1}{4!} \frac{1}{N_f^3 N_f^2} (F_4 - 6F_2 A_2 - F_0 A_4 + 6F_0 A_2^2) , \tag{A.54}
\]

where we used again that $A_n$ and $F_n$ are zero for $n$ odd and $\mu = 0$. Hence the odd derivatives in the expansion vanish. Note that these expansion coefficients also control the quark mass dependence of the quark number susceptibility given in Eq. (3.12). The first derivative of the isovector susceptibility with respect to the quark mass,

\[
\frac{\partial (\chi I / T^2)}{\partial m / T} = \frac{1}{N_f^3} \left[ \frac{n_f}{4} \frac{\partial^2 (\ln \det M)}{\partial \mu^2 \partial m} \right] + \left( \frac{n_f}{4} \right)^2 \frac{\partial^2 (\ln \det M)}{\partial \mu^2} \frac{\partial M^{-1}}{\partial m} - \left( \frac{n_f}{4} \right)^2 \frac{\partial^2 (\ln \det M)}{\partial \mu^2} \frac{\partial M^{-1}}{\partial m} \right] , \tag{A.55}
\]

for which we have introduced the Taylor expansion in Eq. (3.13) requires the calculation of further expectation values $\mathcal{I}_n$,

\[
\mathcal{I}_2 = \langle C_2 \rangle + \langle C_0 D_2 \rangle , \tag{A.56}
\]

\[
\mathcal{I}_3 = \langle C_3 \rangle + \langle C_2 D_1 \rangle + \langle C_1 D_3 \rangle + \langle C_0 D_2 D_1 \rangle + \langle C_0 D_3 D_1 \rangle , \tag{A.57}
\]

\[
\mathcal{I}_4 = \langle C_4 \rangle + 2 \langle C_3 D_1 \rangle + 2 \langle C_2 D_3 \rangle + 2 \langle C_2 D_2 \rangle + \langle C_2 D_1^2 \rangle + 2 \langle C_1 D_2 D_1 \rangle + \langle C_0 D_3 D_1 \rangle + \langle C_0 D_2^2 \rangle + \langle C_0 D_2 D_1^2 \rangle . \tag{A.58}
\]

With these and the coefficients $B_n$ and $F_n$ one finds for the expansion coefficients,

\[
c_2^{\tilde{\psi}\psi} & = \left. \frac{1}{2} \frac{\partial (\chi I / T^2)}{\partial m / T} \right|_{\mu=0} = \frac{1}{2} \frac{1}{N_f^3} (\mathcal{I}_2 - B_2 F_0) , \tag{A.59}
\]

\[
c_4^{\tilde{\psi}\psi} & = \left. \frac{1}{4!} \frac{\partial^3 (\chi I / T^2)}{\partial (\mu_q/T)^2 \partial m / T} \right|_{\mu=0} \\
& = \frac{1}{4!} \frac{1}{N_f^3 N_f^2} (\mathcal{I}_4 - I_2 A_2 - B_4 F_0 - B_2 F_2 + 2B_2 F_0 A_2) . \tag{A.59}
\]

36
Finally we present the expansion of $\chi_{\bar{\psi}\psi}$ which is generated in analogy to the isovector susceptibility by using $C_2^0$ as a kernel in Eq. (A.20). We find

\begin{align}
G_0 &= \langle C_0^2 \rangle, \\
G_1 &= 2 \langle C_1 C_0 \rangle + \langle C_0^2 D_1 \rangle,  \\
G_2 &= 2 \langle C_2 C_0 \rangle + 2 \langle C_1^2 \rangle + 4 \langle C_1 C_0 D_1 \rangle + \langle C_0^2 D_2 \rangle + \langle C_2^2 D_1^2 \rangle,  \\
G_3 &= 2 \langle C_3 C_0 \rangle + 6 \langle C_2 C_1 \rangle + 6 \langle C_2 C_0 D_1 \rangle + 6 \langle C_1^2 D_1 \rangle + 6 \langle C_1 C_0 D_2 \rangle + \langle C_0^2 D_3 \rangle + 6 \langle C_1 C_0 D_1^2 \rangle + 3 \langle C_0^2 D_2 D_1 \rangle + \langle C_0^2 D_1^3 \rangle,  \\
G_4 &= 2 \langle C_4 C_0 \rangle + 8 \langle C_3 C_1 \rangle + 6 \langle C_2^2 \rangle + 8 \langle C_2 C_0 D_1 \rangle + 24 \langle C_2 C_1 D_1 \rangle + 12 \langle C_2 C_0 D_2 \rangle + 12 \langle C_2^2 D_2 \rangle + 8 \langle C_1 C_0 D_3 \rangle + 12 \langle C_2 C_0 D_1^2 \rangle + 12 \langle C_1^2 D_1^2 \rangle + 24 \langle C_1 C_0 D_2 D_1 \rangle + 4 \langle C_0^2 D_3 D_1 \rangle + 3 \langle C_0^2 D_2^2 \rangle + 8 \langle C_1 C_0 D_1^3 \rangle + 6 \langle C_0^2 D_2 D_1^2 \rangle + \langle C_0^2 D_1^4 \rangle. 
\end{align}

These expectation values satisfy,

\begin{equation}
\frac{\partial G_n}{\partial \mu} = G_{n+1} - G_n A_1.
\end{equation}

The expansion of the disconnected chiral susceptibility defined in Eq. (3.14) is then given by,

\begin{align}
c_0 \equiv \frac{\chi_{\bar{\psi}\psi}}{T^2} \bigg|_{\mu=0} &= \frac{N_r}{N^3_3} \left( G_0 - F_0^2 \right),  \\
c_2 \equiv \frac{1}{2} \frac{\partial^2 \chi_{\bar{\psi}\psi}/T^2}{\partial (\mu_q/T)^2} \bigg|_{\mu=0} &= \frac{1}{2N^3_3 N_r} \left[ G_2 - G_0 A_2 - 2 \left( F_2 - F_0 A_2 \right) F_0 \right],  \\
c_4 \equiv \frac{1}{4!} \frac{\partial^4 \chi_{\bar{\psi}\psi}/T^2}{\partial (\mu_q/T)^4} \bigg|_{\mu=0} &= \frac{1}{4! N^3_3 N_r^3} \left[ G_4 - 6 G_2 A_2 - G_0 A_4 + 6 G_0 A_2^2 - 6 \left( F_2 - F_0 A_2 \right)^2 - 2 \left( F_4 - 6 F_2 A_2 - F_0 A_4 + 6 F_0 A_2^2 \right) F_0 \right].
\end{align}
