Abstract

Introduction: The Post-traumatic Stress Disorder (PTSD) is a group of persistent psychological and physiological symptoms due to a traumatic, severe, event. Only few studies focused on the effects of Covid-19 on psychosocial outcomes in children with Type 1 Diabetes (T1D) and their parents.

Aim of the study: The aim of this study was to evaluate the presence PTSD in parents of children with T1D during COVID-19 pandemic lockdown.

Patients and methods: In the period between March and May 2020 we submitted the “Impact of Event Scale – Revised” (IES-R) questionnaire to the parents of 34 children with Type 1 Diabetes, asking them to express their emotions about the ongoing Covid-19 pandemic.

Results: A total of thirty mothers (mean age 43.0 ± 4.2 years) and 25 fathers (mean age 45.6 ± 5.9 years) participated in the survey and completed the questionnaires. 29.1% of parents had a score that allows to define a clinically relevant level of PTSD; ten mothers and 6 fathers had a PTSD clinically relevant score, corresponding, respectively, to 28.4 and 24% of total mothers and fathers. Finally, mothers and fathers, both express PTSD symptoms mainly in the form of intrusion and hyperarousal.

Conclusions: The present study confirms a high prevalence symptoms related to PTSD in mothers and fathers of children with Type 1 Diabetes. We believe that psychosocial outcomes of the COVID-19 pandemic should be taken into account in the planning of the next future assistance for children with T1D.

Keywords: Pediatric diabetes, Post-traumatic stress disorder, SARS-CoV-2, Covid-19

Introduction

Type 1 diabetes (T1D) is one of the most common chronic diseases in infancy [1] and the most frequent endocrinopathy in childhood. Pediatric diabetes management requires complete parental dedication and involvement and exposes the whole family to daily challenges, related to the need for frequent blood glucose monitoring, intensive insulin therapy and specific dietary indications [2, 3].

The Post-traumatic Stress Disorder (PTSD) is a group of persistent psychological and physiological symptoms due to a traumatic, severe, event. As reported in the Diagnostic Statistical Manual (DSM) of Mental Disorders (4th and 5th editions) a post-traumatic event is classified as a life-threatening event and it is perceived as a risk for physical and mental integrity. PTSD belongs to a category, called “Trauma- and Stressor-Related Disorders” [4, 5].

The acute onset and the chronic diabetes management are, both, related to PTSD. Studies have found that a diabetes diagnosis in a child is associated with psychological...
distress among parents. In particular, a study of newly diag- 

nosed children with diabetes showed that nearly one-

fourth of mothers and fathers met criteria for PTSD 6 

weeks postdiagnosis [6].

Usually, parents of children with diabetes report ini-

tially an acute stress, strictly related to diabetes diagno-

sis. This psychological status can be followed by a 

chronic, persistent stress, essentially related to traumatic 

aspects of medical treatment.

Sars-Cov-2 (Covid-19) infection has first been reported 

in Wuhan, China in December 2019 and so far, it af-

fected about one hundred and ten millions patients in 

more than 220 countries and has caused more than 

2,400,000 deaths [7, 8]. In Italy lockdown of the entire 

country has been claimed in March 9th, 2020 in order to 

prevent/reduce the spread of pandemic. It lasted until 

mid-May and has forced the entire Italian population to 

a considerable psychological distress [9].

Indeed, the lockdown and the fear of Covid-19 pan-

demic greatly influenced our society. The majority of 

scientific studies have focused on biochemical aspects or 

on the interaction between the virus and existing dis-

eases. Medical effects have received the most attention, 

whereas only few studies focused on the Covid-19 pan-

demic direct effect on mental health and psychosocial 

attitude.

Pediatric T1D is a very fragile context, in which a 

destructing event, as was the lockdown in the acute 

phase of the pandemic, can induce emotional adaptation 

disorders such as PTSD. It, therefore, seems important 

to underline the psychological relatedness of the SARS-

COV2 infection with its possible consequences. In par-

ticular, the COVID-19 outbreak would result in higher 

levels of psychological distress among people and fam-

ilies managing with T1D.

Aim of the study

The aim of this study was to evaluate the presence PTSD 
in parents of children with T1D during COVID-19 pan-
demic lockdown.

Patients and method

In the period between March and May 2020, we con-

secutively interviewed the parents of 34 children with 

T1D followed at the Diabetes Unit of the Bambino Gesù 
Children’s Hospital, Rome – Italy. Patients involved in 
the study were all affected by Type 1 Diabetes, with a 

diabetes duration of at least 1 year and a reference age 
range between 1 and 18 years; in order to avoid the psy-

chological distress related to the onset of the disease, we 
excluded families of patients with recent diagnosis. The 

interview was done in a tele-assistance context, which 

was the prevailing assistance mode during the lockdown 
period. During the lockdown period the center per-

formed “in presence visits” only for emergency issues 
and those families were excluded from the interview. 
The study was conducted according to the Declaration 
of Helsinki. Participants provided informed consent. Po-
tential conflict of interest do not exist. Patients’ data are 
available and the paper did not request access to re-

search funds.

We submitted the “Impact of Event Scale – Revised” 
(IES-R) questionnaire to the partecipants, asking them 
to express their emotions about the ongoing Covid-19 
pandemic.

The IES-R is a self-report 24-item questionnaire, used 
in order to assess subjective distress caused by traumatic 

events. Items directly refers to 14 out of the 17 DSM-IV 
symptoms of PTSD. Respondents are asked to identify a 
specific stressful life event and then indicate how much 
they were distressed or bothered during the past 7 days 
by each “criticism” listed. Items are rated on a 5-point 
scale ranging from zero (“not at all”) to four (“ex-
tremely”). The IES-R yields a total score and according 
to the final score, partecipants are allocated in a specific 
range that defines the presence and the severity (mild to 
very severe) of traumatism.

Results

A total of thirty mothers (mean age 43.0 ± 4.2 years) and 

25 fathers (mean age 45.6 ± 5.9 years) participated in the 
survey and completed the questionnaires, without miss-
ings items.

The mean total scores and those relating to the “Avoidance, Intrusion and Hyperarousal” sub-scales are reported in Table 1. Mothers have a higher average score than fathers.

Analyzing the individual answers, the following data were highlighted:

1) Sixteen out of 55 parents (29.1%) had a score that 
allows to define a clinically relevant level of PTSD 
(raw scores above 33)

Table 1 Mean scores of the IES-R questionnaire

|                      | Total mean score | Avoidance scale mean score | Intrusion scale mean score | Hyperarousal scale mean score |
|----------------------|------------------|---------------------------|---------------------------|-------------------------------|
| Total n.55           | 2.96             | 0.93                      | 1.13                      | 0.92                          |
| Mother n.30          | 3.15             | 0.96                      | 1.16                      | 1.32                          |
| Father n.25          | 2.72             | 0.87                      | 1.02                      | 1.11                          |
2) Ten mothers and 6 fathers had a PTSD clinically relevant score, corresponding, respectively, to 28.4 and 24% of total mothers and fathers
3) Overall, the percentage of parents with active stress symptoms is generally high in our sample; mothers and fathers, both express PTSD symptoms mainly in the form of intrusion and hyperarousal (Fig. 1)

Finally, we made a comparison analysis between parents with symptoms related to the PTSD area and those without symptoms; this analysis demonstrates a significant age difference between parents reporting high levels of stress and those reporting symptom-free status (42 vs 45,5 years).

Conclusion
In a previous evaluation [10], we described a clinically relevant presence of trauma in a high percentage of mothers and fathers of T1D children, affecting also the Quality of Life of entire families. Also a recent review [11] on the psychosocial outcomes of the Covid-19 pandemic has highlighted how the periods of forced quarantine performed by different states worldwide have caused or at least favored the appearance of psychological, as well as physical, consequences; these include PTSD as a critical element in the management of children and adolescents affected by diabetes during this peculiar historical moment. The present study confirms a high prevalence of PTSD symptoms in this category of patients. About a third of families of children and adolescents with diabetes experience symptoms related to the trauma area. In particular, in our present assessment mothers and fathers of children and adolescents with T1D express PTSD symptoms mainly in the form of intrusion and hyperarousal. This could have an impact on glycometabolic control and perhaps on the path of management autonomy that these patients need to achieve.

The limitation of the present study is that there is no interview to the same families with the same questionnaire at the first post-lockdown visit in presence.

In the next future it would be indeed interesting to understand if the stress symptoms were only related to the lockdown period.

In conclusion, we believe that the presence of symptoms related to PTSD should be taken into account in the planning of the assistance to be reserved for families of children and adolescents with T1D, especially in the next phase of routine recovery of diabetes management. Future studies will help to better understand whether the psychosocial outcomes of the COVID-19 pandemic will have an impact on glycometabolic control metrics.

Authors’ contributions
CC, AD, RS and VP engaged in literature retrieval of the articles, have analyzed the results and wrote the manuscript. NR contributed to wrote the manuscript and discussed on literature analysis. SC critically revised the manuscript. All authors approved the manuscript.

Declarations
Ethics approval and consent to participate
The study was conducted according to the Declaration of Helsinki and was ethically approved as part of the Systematic Monitoring Program and Continuous Improvement of the Quality of Assistance in Italian Pediatric Diabetology. Participants provided informed consent. Patients’ data and questionnaires are available in the medical records. Potential conflict of interest do not exist. The paper did not request access to research funds.

Competing interests
The authors declare that they have no competing interests.
